*With Observations on the Pathological Findings in
their Relation to the "Epidemic" Jaundice
of the Dardanelles.*

BY

WILLIAM CAMPBELL, M.B., CH.B. EDIN., B.Sc.(P.H.),
LIEUTENANT R.A.M.C.,

O.C. A.M.S. PATHOLOGICAL LABORATORY, CAPE HELLES; ACTING
PATHOLOGIST, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH;
DEMONSTRATOR OF PATHOLOGY, UNIVERSITY OF EDINBURGH.

Cases of ascending infection of the bile ducts, liver, and gall bladder became extremely common during October, 1915, amongst our troops on the Gallipoli peninsula. The cases, as we met with them in the early days of their illness, may be grouped clinically into three categories:

1. Jaundice, associated with a variable degree of pyrexia, and usually enlarged and tender liver.
2. Acute cholecystitis without jaundice.
3. A combination of the first two types, with jaundice accompanied by acute cholecystitis.

According to our observation, the three classes occur with a relative frequency that corresponds with the order given above, though the patients with cholecystitis may well develop jaundice at a later stage. The following case is reported in order to draw attention to the danger of an acute gangrenous inflammation of the gall bladder—a condition which is in any event of extreme gravity, and, apart from prompt surgical intervention, is almost inevitably fatal from general peritonitis.

Case.

Pte. S., R.A.M.C.(T.), aged 22, reported to one of us (F. B. S.) on sick parade on October 5th, 1915, complaining of the following symptoms: (1) Pain in the epigastrium that had been constant, slight, and aching in character for four or five days; (2) a cough that was worse at night, aggravating the pain; (3) general malaise, anorexia, and slight headache for the same period. There was no history of vomiting, though there had been occasional nausea and retching after food. There was nothing irregular in the frequency and character of the urine or faeces, though he had suffered from diarrhoea a few weeks before. He had been inoculated against typhoid (two doses) about twelve months before.

On examination the temperature was normal. There were no abnormal physical signs in the chest. The tongue was not quite clean, and there was indefinite epigastric tenderness. He was treated as a case of simple indigestion.

On the following day the symptoms were the same, and the temperature still normal. On the morning of October 7th he complained of pain across the lower chest on respiration. The temperature was 99.2°. The chest was quite clear. The epigastric tenderness was more marked but not definitely localized. The tongue was coated yellow, and there was a left follicular tonsillitis. That evening the man complained that his pain was worse, and he was admitted to the dressing station tent with a temperature of 102° F. During the night the pain grew worse, and the patient vomited several times.

On the morning of October 8th he was evidently very ill indeed. The temperature was 102.8°, pulse 120, and he was flushed and showed a marked "abdominal facies." On

examination of the abdomen respiration was shallow, jerky, painful, and limited to the thorax, the abdomen being almost immobile. On palpation there was general abdominal tenderness and rigidity, but all down the right side it was most marked, and in the right hypochondrium the tenderness was peculiarly exquisite. Percussion did not reveal any shifting dullness in the flanks. The liver dullness was more limited than usual.

Perforation of an inflamed gall bladder with spreading peritonitis was diagnosed, and the patient was removed to the main dressing station of the 1st East Lancashire Field Ambulance for immediate operation.

Operation.—Captain J. M. Postlethwaite anaesthetized with chloroform, and Captain Haskins assisted. Subcutaneous saline was given into the left axilla during the operation. A vertical incision through the right rectus was made over the gall bladder. A considerable quantity of turbid, foul-smelling, bile-stained fluid was found in the peritoneum in the right kidney pouch, extending down into the right iliac fossa and pelvis. The gall bladder, which proved to be unusually difficult of access, because so far back under the liver, and adherent, was examined after the peritoneal cavity had been packed off with gauze. It was distended and deeply congested. It showed no gross perforation, but on its inferior aspect, showing up in marked contrast against the surrounding purple, was a green gangrenous area rather larger than a shilling, with two or three smaller discrete patches of gangrene round it. No gall stones were present. The liver was normal in colour and consistency, and was not enlarged. Cholecystectomy was hardly feasible owing to the anatomical peculiarity of the case and the lack of appropriate instruments, so a drainage tube was inserted through the gangrenous patch near the fundus and sutured in. The gall bladder contained somewhat turbid, foul-smelling bile under considerable tension. A gauze drain was inserted alongside of the tube in the gall bladder, and the peritoneal cavity swabbed dry. The abdomen was closed with through-and-through silkworm-gut sutures.

Progress.—Rectal salines were given every four hours for the first twenty-four hours, and the patient was kept propped up in the Fowler position. Bile drained away freely, but two days later the patient was perceptibly jaundiced, though it soon faded. He improved at first. The abdomen became soft and mobile, the bowels were freely moved, and it was evident that there was no further peritonitis, though there was some suppuration in the abdominal wall. But the temperature remained high, and a typical clinical picture of severe typhoid fever gradually developed. For about ten days the temperature varied between 103° and 105°, with a pulse of 120 to 130. There were frequent loose motions, he was greatly prostrated, and the condition was complicated by an area of pneumonic consolidation at the base of the left lung, with a small serous effusion in the pleural cavity. Towards the end of the third week of his illness, however, the temperature began to drop and the pulse to improve, and at the time of writing (October 29th), though very emaciated, and still too weak for removal to a hospital ship, we hope that he is fairly on the way to ultimate recovery. The main credit for this is due to his nursing orderlies, and particularly to Lance-Corporal Gregory, R.A.M.C.(T.), who has shown the most unremitting care and devotion in a very difficult case.

Pathological Investigation.

A specimen of fluid from the gall bladder and subsequently several specimens of faeces and one of blood, for examination by cultural methods, were submitted to Lieutenant William Campbell, M.B., Ch.B., R.A.M.C., at the Pathological Laboratory, Cape Helles, and we are greatly indebted to him for the following reports:

Specimen of Fluid from Gall Bladder (October 16th).

1. I have been unable to find an entamoeba.
2. *Mycobacterium tetragenus* is present.
3. *Staphylococcus pyogenes albus* is present.
4. The only other organism isolated is an organism giving the cultural reactions of a paratyphoid bacillus and agglutinating up to titre with the agglutinating serum of *B. paratyphosus* B (1:4,000 Lister Institute paratyphoid B serum). Isolation of this organism was easy, and it is likely that it was present in greater numbers than either *M. tetragenus* or *S. pyogenes albus* owing to the number of colonies of this organism (paratyphoid B) which came up on plate cultivation. *B. coli communis* was not isolated, and the above represent the total findings.

NOTE.—Since these notes were written (October 29th, 1915) we have been informed that the patient died in hospital in Alexandria.

October 24th. The blood culture taken from the above case (October 21st) has remained sterile.

Three specimens of faeces (No. 1, No. 2, and No. 3) were sent to the laboratory on October 19th, 20th, and 21st respectively.

Specimen of Faeces No. 1 (October 19th).

Report.—Thin, offensive stool, showing no blood or mucus to the naked eye. Microscopically, no entamoebae found. Active *Trichomonas hominis* crows all the fields examined. No blood cells were found. Specimens plated on MacConkey's and on Endo's medium on October 19th. Likely colonies picked off after culture and examined further.

Result (October 24th): *B. paratyphosus* B isolated.

Specimen of Faeces No. 2 (October 20th).

Report.—Naked-eye appearance: Pea-soup type of stool; no blood and no mucus seen. Microscopically, active *Trichomonas hominis* present in large numbers; entamoebae present in small numbers. No blood cells found. Specimen plated on MacConkey's medium, October 20th.

Specimen of Faeces No. 3 (October 21st).

Report.—Naked-eye appearance: As in Specimen No. 2. Microscopically, active *Trichomonas hominis* present in large numbers; entamoebae (cysts) present in small numbers; no blood seen. Specimens plated on MacConkey's medium and on Endo's medium, October 21st.

* Since *B. paratyphosus* B has been isolated from the specimen of faeces No. 1, and as no other organisms of the typhoid or of the dysentery group were isolated from it, I do not think it necessary to carry the examination of specimens No. 2 and No. 3 further.

The above pathological report is of great value in that it may indicate the nature of the infection that gives rise to a considerable proportion of cases in the epidemic under consideration. Our specimen of bile was sent to Lieutenant Campbell with a request that he should look for the entamoeba of dysentery or any other organisms present, and we had no suspicion of paratyphoid before receiving his report. On clinical grounds there was a good deal of presumptive evidence for the view that the cases constituting this epidemic may be secondary to dysentery and due to the entamoeba. The great majority of patients with jaundice or cholecystitis give a history of dysentery or diarrhoea, commonly ceasing two to four weeks before the hepatic symptoms began. But few men who have been many weeks on the peninsula have not had some diarrhoea or dysentery at some time, so that too much weight cannot be given to the suggestive association of the two epidemics. We have, moreover, found a few patients with epidemic jaundice who deny having had any diarrhoea or dysentery at all during the campaign. It is plain that the etiological problem is essentially one for the laboratory, and it is only from cases requiring operation, or from post-mortem examinations, that the necessary material from the biliary tract can be obtained. Without claiming for a moment that this very important etiological problem can be settled by the evidence forthcoming from a single case, the presence of *B. paratyphosus* B in the gall bladder in great numbers is an arresting and suggestive fact that should be borne in mind in further investigations. If it should be established from a series of cases that the most serious cases in this epidemic are due to this organism, it may prove possible by prophylactic inoculation to save our troops from this disease.

Observations on the Pathological Findings in their Relation to the "Epidemic" Jaundice of the Dardanelles, by WILLIAM CAMPBELL, M.B., Ch.B. Edin., B.Sc. (P.H.), Lieutenant R.A.M.C.

If any medical officer serving in the zone of active operations on the Gallipoli peninsula were asked to mention those medical conditions which, from the number of cases affected by them, were of greatest importance, he would immediately answer: (1) Diarrhoeal diseases, (2) pyrexias of uncertain origin, (3) jaundice (? epidemic), and he would inevitably add the remark, "In October, 1915, the numbers of cases of jaundice had been so remarkably large that they constituted a definite epidemic." I have queried the term "epidemic" above because it is exceedingly doubtful whether these cases form a true epidemic in the sense in which I have been accustomed to accept the term.

The designations "Weil's disease" and "epidemic jaundice" are commonly used by medical officers to describe the cases of jaundice occurring, and many such cases came from the trenches to the clearing station with one or other of these two terms already marked on their tickets.

If by "epidemic" it is meant that many cases of jaundice occurred amongst the troops in a given area, then the use of the term may be defensible; but if it be

implied at the same time that the cases are in any sense infectious in character, there can be no doubt that the qualification "epidemic" should be given up unless and until the jaundice be proved on epidemiological and bacteriological grounds to be so.

While numerous cases of jaundice showed no elevation of temperature, there were very many others accompanied by definite pyrexia. This latter fact would seem to point to some organismal cause, especially as in a few cases which have been observed an antecedent pyrexia has been noticed during the two or three days immediately preceding the appearance of yellow coloration of the conjunctivae and skin.

There is at present little to support the view that the jaundice is haematogeneous in origin, and the probability that most of it is due to ascending infection of the biliary apparatus (catarrhal jaundice) is strong. This may be stated with emphasis, because, as Captains Morley and Smith have pointed out above, practically every one who has been a short time on the peninsula admits to having suffered from diarrhoea of some description; and it is an interesting fact that, with the advent of the colder weather, the decrease in the number of cases of diarrhoea from all causes marched practically *pari passu* with a corresponding increase in the number of cases of jaundice.

Regarding this, attention may be drawn to the view mentioned above, and based on clinical grounds, that there is a good deal of presumptive evidence that the cases constituting the epidemic may be secondary to dysentery, and due to the amoeba. But, while it is true that of those cases of diarrhoea the causes of which have been ascertained in the laboratory amoebic dysentery has formed a large proportion, it must be borne in mind that far from all the diarrhoeal cases are of amoebic origin; and it is to be noted that cases of enteric fever due to the paratyphoid organisms (including a smaller number due to *B. typhosus*), the smaller number of diarrhoeal cases which have been due to the Shiga-Flexner group of bacilli, the few cases due to the trichomonas, and finally those cases whose specific cause could not be ascertained by the bacteriologist, all go to make up the complement of diarrhoeal diseases from all causes.

If, then, it be sound to take the apparent parallelism between the incidence rate of diarrhoeal diseases from all causes and that of the so-called "epidemic" jaundice as indicating some relation between the two, it is reasonable to suppose that it is unlikely that the cases of jaundice have a uniform bacteriological cause.

Further, it was a matter of common knowledge on the peninsula that amongst apparently healthy individuals, even in those cases who have had no actual diarrhoea, a condition of chronic laxity of the bowels, unaccompanied by pyrexia, in which two or three bulky pultaceous motions were passed daily, was practically universal. This fact indicates that a very large amount of refuse matter is being got rid of, and would therefore seem to point to the diet containing too much indigestible material. But, as the army diet is reasonably good in quantity and quality, it rather points to there being some underlying catarrhal inflammation of the gastro intestinal tract, which again is in favour of the view that much of the jaundice is due to ascending infection of the common bile duct from the intestine. It is improbable, therefore, that all cases of "epidemic" jaundice are due to a single specific organism.

On the other hand, the occurrence of numerous cases of cholecystitis, with or without jaundice, is striking, and these cases of cholecystitis may afford a possible clue to the cause of some of the cases of "epidemic" jaundice in that they may be due to an organism whose growth is favoured by bile. Such an organism, having multiplied in the gall bladder, might very well produce a secondary descending infection of the common bile duct.

It must be remembered, however, that, as there have been many cases of amoebic (*Löschia histolytica*) dysentery, and that as numerous individuals, who have not suffered from actual dysentery, harbour the amoeba in their intestines, many cases of cholecystitis may represent the so-called "hepatitis," which is characterized by pyrexia and by tenderness in the right hypochondrium, and recognized as being a frequent complication of amoebic dysentery. Indeed Captains Morley and Smith have referred above to the tentative suggestion that the epidemics of cholecystitis and of jaundice may be in large part secondary

to dysentery and due to the amoeba. At the same time, I am not aware that jaundice has been found in places, where amoebic dysentery is endemic, to be a particularly common sequel of infection with the amoeba.

It will be gathered that, while the etiology of the "epidemic" jaundice of the Dardanelles is still uncertain, the problem of its elucidation gives great scope for laboratory investigations, especially to those bacteriologists who are fortunate in working at the base hospitals, where the cases can be kept for some time and who have quiet and settled conditions in which to prosecute their work. The matter can only be cleared up in the laboratory, for it must be granted that, from the clinician's point of view, the problem is not simple because he finds his cases of jaundice complicated in various ways.

For instance, the jaundice may be slight or pronounced in degree, the duration may vary from one or two days up to several weeks, and it may or may not be associated with one or more of the following conditions:

(a) *Pyrexia of indefinite character*; sometimes transient, but frequently of the nature of a low continued fever. Many cases, however, are afebrile and some run a subnormal temperature.

(b) *Digestive disturbances* (generally present); usually marked; evidenced in some cases by nausea and anorexia only, in others by intestinal colic, and in a few by diarrhoea.

(c) *Cholecystitis*, with marked tenderness in the right hypochondrium; pain sometimes referred to back as well.

Captains Morley and Smith have noted above that cases of jaundice following an attack of cholecystitis, as well as other cases of acute cholecystitis without jaundice, are also met with. Further, medical officers find that in nearly all cases of jaundice the patient gives the information that he suffered from diarrhoea and colic at some time or other on the peninsula, but, owing to the prevalence of diarrhoeal diseases, this is not to be wondered at.

Broadly speaking, the cases of "epidemic" jaundice might be divided into two groups:

1. Jaundice with pyrexia.
2. Jaundice with no elevation of temperature.

It is doubtful, however, whether this classification would help us, for the problem is complicated by the fact that temperatures of irregular type and uncertain origin are by no means uncommon, and occur equally in patients with and without jaundice. Again, typhoid fever occurring in inoculated cases shows itself as an atypical and generally abortive fever. The same is true in some degree of enteric fever due to the paratyphoid organisms, because, although the immunity conferred by antityphoid inoculation has been regarded by some as being homologous, and although many paratyphoid infections occurring in patients inoculated against *B. typhosus* give a good clinical picture of enteric fever, there is strong evidence for believing that antityphoid inoculation gives a partial immunity to the paratyphoid fevers, and that, therefore, many atypical and abortive cases of these in all probability occur as well.

It follows from these facts that the diagnosis of febrile conditions has become much more difficult for the clinician, who too often finds himself left in doubt as to what value should be placed on many a temperature chart for diagnostic purposes. This is true generally, and it is true of cases of jaundice with pyrexia. The classification of cases of "epidemic" jaundice into febrile and afebrile varieties may on this account not be of so much value to him as might at first appear.

Pyrexia occurring in these cases indicates the facts (a) of infection and (b) of reaction on the patient's part; but cases of mixed infection are not unknown, and the temperature chart may therefore indicate reaction not to one but to several organisms. Or, in cases of mixed infection, the reaction may be to one organism, while other ordinarily pathogenic organisms found in such cases may be mere saprophytes in the intestine. In respect of this it will be noted that, in the case recorded above, *B. paratyphosus* B occurred in the faeces in conjunction with *Trichomonas hominis* and *Entamoeba histolytica*.

The first specimen sent to me from this case was one of bile, and from it *B. paratyphosus* B was isolated, as well as *Micrococcus tetragenus* and *Staphylococcus pyogenes*.

albus. The two organisms last named I regard as contaminations. No organism was obtained from the blood culture taken from the same case.

Without attempting to assess to the *Trichomonas* and the *Entamoeba* in this particular case their pathological value (if any) in the production of the gangrenous cholecystitis, it seems fair to regard the *B. paratyphosus* B as having been the cause of the condition. To the clinical pathologist who has had the opportunity of seeing patients with "epidemic" jaundice, the case suggests one or two points which I shall now discuss very briefly.

As is generally recognized, catarrhal jaundice commonly occurs without cholecystitis; similarly, cholecystitis is very frequently unattended by jaundice. Both facts are capable of a simple anatomical explanation. But in some cases in the Gallipoli epidemic jaundice followed a definite cholecystitis, and one hears as well of numerous cases of jaundice in which a history of troublesome spasmodic pain in the right hypochondrium, highly suggestive of an antecedent cholecystitis, was obtained. It may therefore be that the relation between the cholecystitis and the jaundice is of greater importance than has been recognized hitherto, and it is possible that cases of cholecystitis treated by operation will furnish to the bacteriologist the most hopeful material for the solution of an etiological enigma.

From this point of view the case recorded by Captains Morley and Smith may be of special value. It shows, at all events, that in a patient inoculated against typhoid fever a paratyphoid organism in the early days of infection may ascend from the intestine to the gall bladder and there settle without causing more than an initial and indefinite epigastric tenderness associated with anorexia and headache; that later its numbers and virulence may be so increased as to cause actual gangrene of the gall bladder; and that, therefore, it is not improbable that from the gall bladder, in cases of cholecystitis, a subsequent descending infection of the common bile duct with consequent jaundice may take place—an infection due to an organism which has meantime been multiplying in the bile. This may explain numerous cases of jaundice with pyrexia, especially those cases which give a history suggesting a previous cholecystitis.

It is likely, then, that a close study of those organisms whose growth is known to be favoured by bile may help to enlighten us as to the cause, or causes, of the "jaundice with pyrexia" which occurred in the Dardanelles; and, although jaundice is not a common complication of ordinary typhoid fever, it is possible that the paratyphoid infections may play a much more important part than the *B. typhosus* in the production of febrile jaundice. The possible connexion between the "carrier" problem and the occurrence of febrile jaundice suggests itself; and it would be interesting to know how many cases of "epidemic" jaundice, bacteriologically examined, have yielded a paratyphoid organism.

Be this as it may, I am for various reasons strongly of the opinion that it is highly improbable that the cases of jaundice occurring in the Gallipoli "epidemic" have, by any means, a uniform specific bacterial cause.

REMOVAL OF INTRACRANIAL FOREIGN BODY UNDER X RAYS.

BY

JOHN ROBERT LEE, M.D., B.S.MELB., F.R.C.S. EDIN.,
TEMPORARY LIEUTENANT R.A.M.C., FULHAM MILITARY
HOSPITAL, LONDON, W.

THE following case of gunshot wound of the head, with a piece of shell in the brain, illustrates the value of the use of an electro-magnet or x-ray screen for removal.

A lance-corporal received a gunshot wound on September 25th, 1915, in France. The piece of shell entered the skull about the middle of the left temporal region. He had an injection of antitetanic serum four hours after the injury. When admitted to this hospital on October 9th he was conscious, complained that he could not sleep, and that he had considerable pain. The superficial wound in the side of the head had healed. The temperature was 99° and the pulse 60. Next morning he vomited.

A skiagram taken on October 11th showed some depressed fragments of the internal table round a small hole in the middle

of the squamous portion of the left temporal bone, and the shadow of a piece of shell about $\frac{1}{2}$ in. by $\frac{1}{4}$ in. was seen on the plate 1 in. behind the hole and $\frac{1}{2}$ in. beneath the surface.

On October 13th Mr. Leslie Paton examined the eyes (pupils not dilated) and found: The right optic disc, highest point + 3 D., edges blurred, veins distended, general retina + 5, swelling 2+. Left optic disc, highest point + 5 D., general retina + 1, swelling + 4. The patient had sensory aphasia, word-blindness, but no apraxia.

Operation.

A large temporal flap was made, and the opening in the skull enlarged; pieces of depressed bone were removed, the torn edges of the membranes were opened up, and about 2 oz. of thick pus under pressure escaped. The piece of shell could not be felt with the probe, and a rubber tube was put in and free drainage established.

On October 15th another skiagram showed that the piece of shell had dropped further back in the abscess cavity into the occipital lobe. The temperature at this time varied between 97° and 99°, but on October 23rd the evening temperature was 100°, on October 24th 101°, and on October 26th 102°; it then became normal and has remained so ever since. The pulse-rate varied between 64 and 100, and after October 26th was from 72 to 80. On October 23rd the eye appearances were: Right optic disc, highest point + 3.5 D.; left optic disc, highest point + 4 D.; veins still much distended.

A probe was passed down along the abscess track, and a stereoscopic skiagram taken.¹ The fragment of shell was found to be lying in the occipital lobe, one eighth of an inch in front of the tip of the probe and half an inch mesial to it. A steel probe was then passed down the track, and an electro-magnet capable of lifting 14 lb. weight was applied to the probe and held in position for a few seconds, but the bit of shell was not drawn out by this means.

It then seemed to me that it might be possible to see the fragment, and remove it under the x-ray screen, and, after consultation with Dr. Florence Stoney, the radiologist to the hospital, the attempt was made on November 9th. The steel probe was again passed in along the track, and I was able quite clearly to see the probe and the fragment. It was found that the latter had been pulled forward by the magnet, and caught in brain tissue. A crocodile forceps was then passed along the track to the depth of four inches, and after some manipulation the piece of metal was seized and removed. The patient was not under anaesthesia and felt no pain, except just as the sharp edges of the fragment came into contact with the edges of the superficial wound.

On November 13th the patient's general condition was quite good. On November 17th the wound had healed; aphasia was less marked, but he still had some slowing of mental cerebration, and at times difficulty in naming articles, with some loss of memory in naming places and for recent events. The eye symptoms were: Right optic disc still blurred; swelling subsided very much; highest point of disc + 2 D., general retina ametropic; small linear haemorrhages especially in lower part of disc; left optic disc still all blurred; subsidence not so marked in appearance as in the right eye; swelling, highest point of disc + 2 D.; some haemorrhages.

The two practical points demonstrated are: First, the use of an electro-magnet for the removal of portions of shell which are capable of being so attracted; and, secondly, the fact that bits of metal can be demonstrated inside the skull, although the x rays have to penetrate two layers of bone; the surgeon may thus receive very material assistance in such cases by seeing the relationship of fragment to instruments during actual removal.

My thanks are due to Dr. Florence Stoney for the excellent skiagrams and help with the screen; to Dr. Leslie Paton, who kindly worked out the eye conditions; to Major Parsons, the Officer-in-Charge, and to Colonel Peterkin, the D.D.M.S., for permission to publish this case.

¹ One skiagram was reproduced in illustration of a report of this case published in the *Journal of the Royal Army Medical Corps*, January, 1916.

DR. ALLEN WALCOTT has contributed an article on beri-beri in the Amazon basin to the *Journal of the American Medical Association* for December 18th, 1915. He has been for six years in the employ of the Madeira-Mamore Railway, which runs through a dense tropical forest along the east bank of the Madeira River 1,500 miles from the mouth of the Amazon. There is a hospital at Candelaria on the line, but no other for many hundred miles in any direction. Out of 30,430 admissions in four years, 963 cases were diagnosed as beri-beri. On the strength of his own previous experience of this disease in San Francisco and Panama, Dr. Walcott concludes that beri-beri in Brazil is of the same type as is found elsewhere, and its cause is the lack of vitamins in the food. The doctors, nurses, and labourers in the medical department have been completely free from attacks of the disease for the last three years, protected by the special precautionary measures used in other lands where it prevails. These measures are described in detail by Dr. Walcott.

PARACHOLERA.

BY

ALDO CASTELLANI, M.D., M.R.C.P.

THIS term was introduced by me some years ago to denote cases which, though clinically hardly distinguishable from cholera, are due to vibrios somewhat different from true *V. cholerae* (Koch). As well known for many years, vibrios have been described which are somewhat different from Koch's germ, and Hewlett, Cunningham, and myself have suggested that the disease may be due to a group of closely allied vibrios. I will not consider in this paper the numerous cholera-like vibrios found in water, and will limit myself to supposed pathogenic vibrios found in the stools of cases presenting cholera-like symptoms. The most important of these vibrios are the following:

1. *Finkler and Prior's organism*, isolated from cases of so-called cholera nostras in Germany many years ago. Its pathogenicity has been doubted by several observers. According to certain authorities, it would appear that the original strain has been lost and that no modern serological tests have been carried out with it.

2. *Pasquale's Vibrio massahuae*, isolated from cases clinically indistinguishable from true cholera in Massowah

in 1895. According to Pasquale, the organism differs from *V. cholerae* (Koch) in having two terminal flagella at each end. Durham found that this vibrio was serologically identical with a vibrio isolated from the water of certain German rivers by Dumar.

3. *Ruffer's vibrios*. Ruffer has isolated certain vibrios from Mohammedan pilgrims returning from Mecca and suffering from various diseases, but with no cholera symptoms. He has compared these "El Tor vibrios" with vibrios he has isolated from other sources, and distinguishes four groups. Neufeld and Haendel, however, having examined some of these vibrios, consider that they are true cholera.

It must be noted, as observed by Grieg, myself, and others, that in cases of true cholera, together with true *V. cholerae*, vibrios may be isolated which are not agglutinated by cholera serum.

Vibrio kegallensis (Castellani, 1913).

This vibrio, for which I suggested also the name *V. paracholerae*, has been isolated by me, as stated in previous publications, from cases in Ceylon clinically scarcely distinguishable from cholera, with profuse serous diarrhoea, severe vomiting, muscular cramps, etc. It was very abundant in the stools and the only species of vibrio

present. It was found also in the water of a well in Mutale, near which a small epidemic of cholera-like cases occurred. The germ is microscopically and culturally very similar to *V. cholerae*. It is very motile, like true cholera, and it is easily stained by the usual dyes; it is Gram-negative. In stained preparations it has the same shape as the true cholera vibrio, but is perhaps slightly larger and thicker. On agar and gelatine and serum the growth is similar or identical to true cholera. Gelatine and serum are liquefied. Milk is generally rendered acid and clotted or peptonized. In peptone water the pellicle is very slight or absent. The germ does not produce indol, or only an extremely slight trace. It must be remembered, however, that certain strains of true cholera vibrio may produce only a very slight amount of indol, and may practically produce no pellicle in peptone water. The production of haemolysis is inconstant with all the strains of *V. kagallensis* I have examined.

Serological Reactions.

V. kagallensis is not agglutinated by true cholera serum in dilutions higher than 1 in 10 or 1 in 20; cholera vibrio is not agglutinated by *V. kagallensis* serum. The absorp-

tion test and Pfeiffer's test confirm the results obtained by the agglutination test.

Pathogenicity.

I have been unable to reproduce the disease in the lower animals by feeding experiments, but, as is well known, this is the case also with true cholera. Considering that the vibrio was present in the stools of the patients in enormous numbers, and was the only species of vibrio present, the probabilities are, in my opinion, that it is pathogenic.

CONCLUSIONS.

1. The term "paracholera," as I suggested some years ago, might be used to denote cases of cholera-like diseases due to vibrios, which are specifically different from *V. cholerae* (Koch), though closely allied to it.
2. In Ceylon cases of paracholera occur which in all probability are due to *V. kagallensis* vel *paracholerae*.

A CASE OF CHRONIC NON-TUBERCULOUS PERITONITIS IN A CHILD.

BY

CECIL WORSTER-DROUGHT, B.A., M.B., M.R.C.S.,
LATE HOUSE-PHYSICIAN OF THE KVELINA HOSPITAL
FOR CHILDREN, ETC.

As I am unable to find any record of a precisely similar condition to that which occurred in the following case, I venture to consider it sufficiently singular to justify its publication. As regards general appearance and all clinical manifestations, few would have hesitated to diagnose the complaint as the ascitic form of tuberculous peritonitis.

A boy, aged 4½ years; when first seen very bright and intelligent; had suffered from no previous illnesses excepting measles. As a baby he had been fed on cow's milk; his five brothers and sisters were all healthy and there was no tuberculosis in the family. The history of the beginning of his present complaint was indefinite. For about four months he had complained of pain in the "stomach" and occasionally vomited after food; there was no diarrhoea. The abdomen during this period had become larger and larger and loss of flesh had been considerable. There was no suggestion of injury.

Condition when First Seen.—The chest, face, and limbs were very emaciated; the abdomen was large and prominent. The heart and lungs appeared quite normal; pulse 90, respirations 28, temperature 98.8°. A large amount of ascitic fluid was present; there was no pain even upon firm pressure. The subcostal circumference was 24½ in.; the umbilical 21½.

Subsequent Progress.—The condition was diagnosed as tuberculous peritonitis; he was kept in bed and given syrup of iodide of iron; oleate of mercury ointment was rubbed into the abdomen daily. Two days after admission he was tested by von Pirquet's cutaneous reaction. On the right arm bovine tuberculin was used and on the left human tuberculin, with a control underneath each. Both proved positive, the intensity of the two reactions being about equal. The circumference of the abdomen in seven days had increased from 24½ in. to 25½ in. in the case of the subcostal circumference, and from 21½ in. to 22½ in. in that of the umbilical. Owing to the respiratory embarrassment—the respirations were now 40—five pints of dark brown fluid were removed by laparotomy; no glands were felt inside the abdomen, nor were any tubercles seen. A small piece of the parietal peritoneum, cut out and subsequently examined microscopically, showed no tubercles.

Ten days later the wound had quite healed and the stitches were removed, but there was still a small amount of fluid. During the time he had been under observation the temperature had varied between 97° and 98.8°; at no period had it been higher. At the end of another week the temperature suddenly went up to 100° and a purpuric rash appeared over the chest

and arms. A few hours later he became comatose and died the next morning.

The necropsy afforded no evidence of tuberculosis. In the abdomen was a fairly large quantity of fluid and numerous adhesions; the visceral and parietal peritoneum was enormously thickened. The omentum and mesentery were somewhat rolled up, and contained much inspissated pus between and around their layers. Pus of a similar nature was present on other parts of the peritoneum. No enlarged glands were found either in the abdomen, mediastinum, or neck; there was no sign of tuberculous ulceration of the intestine. The heart and lungs were normal, but the stomach wall was very thick. The spleen was soft and not enlarged; the liver indicated chronic congestion; the kidneys, brain, and meninges were normal. With such *post-mortem* revelations it can scarcely be maintained that the *Bacillus tuberculosis* was the organism responsible for the pathological changes, although clearly the condition was due to bacteria of low virulence.

Of the many varieties of chronic peritonitis, the following only need be considered in connexion with this case: (1) Diffuse adhesive peritonitis, (2) chronic proliferative peritonitis, (3) tuberculous, (4) gonorrhoeal, (5) pneumococcal, and (6) idiopathic (so-called) peritonitis.

Although undoubtedly the condition found at the necropsy could be described as diffuse adhesive peritonitis with suppuration, it does not agree with the type to which this name is applied, inasmuch as the latter follows an acute attack. The case differed from one of proliferative peritonitis in that pus and numerous adhesions were present and that the etiological factors were not the same.

The onset and course of the case were certainly more or less typical of chronic tuberculous peritonitis. There was a gradual subacute onset; the temperature varied between normal and subnormal. According to Hutchison, however, the ascitic effusion is rarely large; in this case it was sufficiently great to warrant laparotomy. Further, had the case been tuberculous, one would have found at least some *post-mortem* evidence of tuberculosis. In tuberculous peritonitis the effusion is usually straw-coloured, though occasionally it may be haemorrhagic; in this case it was dark brown. When ascites is present, the peritoneum is almost invariably found to be studded with tubercles.

It has been said that gonorrhoeal peritonitis has been found in males associated with a gonorrhoeal infection. In the case under discussion there is nothing to suggest this.

Pneumococcal peritonitis is more often primary or secondary to some other source of infection than a complication of lobar pneumonia. It is most common in female children, and is very acute; the pus is said to be thin, widely diffused, and with much fibrin. According to Still, primary peritonitis in children beyond the stage of infancy is nearly always tuberculous or pneumococcal. Records of 91 cases of pneumococcal peritonitis in children under 15 years of age, collected by Annand and Bowen, show that the symptoms were always severe, closely resembling, with one exception, the clinical course of diffuse perforative peritonitis. There was the same sudden onset, often with rigors and violent and persistent pain, frequent vomiting, advancing prostration, and early death. In children, however, this condition has been known to give rise to chronic encapsulated abscess, and it is conceivable that the chronic suppuration in this case may have been due to a strain of pneumococci of low toxicity.

Allchin, however, mentions certain forms of peritonitis attended with suppuration which run "a course the duration of which may justify their being designated as chronic." They may continue for many months, the severity of the local condition and the toxic manifestations being insufficient to cause death, though the general health of the sufferer steadily deteriorates. "Such cases," he says, "have been referred to as 'acute progressive fibrino-purulent peritonitis.' It is only in the sense of their duration that they are to be regarded as chronic, being rather of the nature of a succession of acute or sub-acute attacks of localized character." Since this patient's illness did not commence with an acute attack, and during the course of observation showed no rise of temperature indicative of an acute exacerbation, it does not coincide with Allchin's description of acute progressive fibrino-purulent peritonitis.

It appears evident that the end was brought about by a sudden rise in the toxæmia, a fact which also accounts for the purpuric rash. As the evidence in favour of pneumococcal infection is not great, the most one can say is that the case was a somewhat anomalous type of chronic suppurative peritonitis and due to an organism of low virulence, such as *Bacillus coli communis*. Had the clinical appearance not been so typical of tuberculous peritonitis, one would have endeavoured to cultivate the organism from a swab taken at the time of operation. My acknowledgements are due to Dr. T. R. Whiphram for his courtesy in permitting me to make use of the case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE TREATMENT OF LAMBLIA INFECTIONS.

I WAS interested to read in the JOURNAL (March 18th, p. 407) of Drs. Woodcock and Penfold's experiences in the treatment of *Lambliæ* infections. In a paper I recently published in the *Journal of Tropical Medicine and Hygiene* I laid stress upon the importance of repeated and careful examinations of the stools both before and after treatment, and also mentioned some drugs tried by myself. In the doses in which I used them, emetine, beta-naphthol, and methylene blue all failed, completely to sterilize the patient of his infection. An apparent improvement occurred after the latter two, but prolonged examinations showed that this was only of a temporary nature.

I also described toxic symptoms following the administration of the methylene blue. Since then Major Marshall, of Edinburgh, has drawn my attention to a paper by himself and Gee published long ago in India, in which similar symptoms were met with after the use of this drug for malaria. He believes it is due to the difficulty of getting samples of the drug free from zinc chloride, and recommends giving it with extract of hyoscyamus to prevent bladder symptoms. Of other drugs I have used, bismuth alone, salicylic acid alone, salol, thymol, and cyllin have also proved ineffective.

It is specially interesting, then, to hear of Drs. Woodcock and Penfold's apparent cure of a case by the combined use of beta-naphthol and bismuth salicylate. Before finally

concluding, however, that this is a cure, further examinations should be carried out especially after the administration of good saline purges. Though very constant in certain cases, the passage of the cysts in others is equally inconstant, and they apparently may disappear for quite a long time of their own accord. An attack of diarrhoea or a purge often quickly brings them back again.

I recently saw a case heavily infected with *Trichomonas* and proposed treating him with methylene blue, but before doing so I thought I would observe him for a week. The trichomonads disappeared of their own accord, and so far (one month) have not again put in an appearance. If I had given the drug I would naturally have concluded that it had made them disappear. Turpentine, so lauded by French workers, and guaiacol carbonate I note also failed in some of the authors' cases. I am certain that many so-called successes, if followed up for a sufficiently long period (six months to a year), would have to be written off and debited to the failure column. Drs. Woodcock and Penfold's first case approaches the time limit given, though one would like to know how many times "several" really means. Their other cases, examined four and three days after treatment, of course give far too short a time to base any definite conclusions upon.

London, W.

GEORGE C. LOW, M.D.

A CASE OF POTASSIUM CHLORATE POISONING IN AN INFANT.

I FOUND a child aged 4½ months in a prostrate condition. There was marked pallor, with cyanosis of ears and lips and of the hands and feet, which were cold; breathing was quickened and shallow, but not jerky or noisy. The child lay still with eyes open, some contraction of the eyebrows, and an occasional peevish cry. The rectal temperature was normal; the pulse, 204, could be felt at the wrist. There was no cough, and nothing was found abnormal in the lungs. There was no vomiting and nothing abnormal about the abdomen. Some castor oil had been given before arrival, and the bowels had acted normally. The appearance suggested profound toxæmia. The diet had consisted of cow's milk, cream, and sugar of milk; the feeds had been prepared with scrupulous care, the mother herself being a medical graduate. Poisoning by gas-stove fumes was excluded, and the cream used was found on inquiry to be free from any preservative, such as boric acid.

It was noticed on the previous day that the feeds had been taken with some reluctance, but nothing abnormal was noticed about the child until the early morning of the day when first seen. When seen three hours later some brown-black material, the size of a small pea, found on the napkin was thought to be probably faecal until some greenish-yellow urine containing particles of similar material was seen issuing from the urethra. It was evident great destruction of the haemoglobin was in progress, and I suspected a chemical poison. Rough tests showed the supposed sugar of milk to be an inflammable salt of potassium, subsequently proved to be potassium chlorate. Death ensued without convulsions.

Post-mortem Examination.—The musculature was of a dusky red colour. The heart and blood vessels contained soft chocolate-coloured clot, and the walls of the aorta showed patches at intervals of brownish discoloration. The liver, spleen, and kidneys were chocolate in colour, with a "burnt sienna" coloured exudate on scraping. The calices of the kidney and the ureters and bladder were filled with a soft, friable brownish-black material which was not blood clot. The bladder also contained some turbid yellowish-brown fluid.

Reading.

E. W. SQUIRE, M.B.Lond.

AT a meeting of the American Medical Library Association held at Washington in May, 1915, Mr. James F. Ballard urged that all medical libraries should adopt a uniform method of preparing statistics of their contents, and the following recommendations were made:—Everything of over 100 pages is a volume; everything of any size, if bound, is a volume; everything under 100 pages, if unbound, is a pamphlet. Duplicates should not be counted, except second copies of books in general use. Uncatalogued material and incomplete and unbound periodicals should not be included.

Reports of Societies.

DISCUSSION ON GUNSHOT WOUNDS OF THE SPINE.

At the meeting of the Medical Society of London on March 20th a discussion on gunshot wounds of the spine was opened.

MEDICAL ASPECTS.

Captain JAMES COLLIER said that the subject could be considered under the following heads: (1) The nature and mechanism of production of the lesions; (2) the state of the reflexes and of muscle tone in the affected region; (3) the distinction between root lesions and central lesions of the cord; (4) disturbances of sensibility; (5) prognostic indications; (6) the occurrence of rare and unusual phenomena.

The Nature of the Lesions.

The lesions had been caused by high-velocity bullets, shrapnel, fragments of shell casing, and by concussion of high explosives without external wound. The lesions might roughly be classified thus:

1. *Direct lesions*, resulting from the passage of a missile across the spinal canal, whether it touched the spinal cord or not.
2. *Indirect lesions*:
 - (a) Those due to the indriving of bone, etc., into the spinal canal.
 - (b) Impact lesions in which the missile struck against the bony wall of the spinal canal.
 - (c) Concussion lesions from the shock of high explosives.
3. *Secondary Lesions*.—Perithecal and intrathecal haemorrhage, medullary haemorrhage and thrombosis, meningitis, oedema. These lesions were important as the cause of the deepening of symptoms, often at a considerable time after the injury.
4. *Remote lesions*, which might be found anywhere in the spinal cord and chiefly near the surface. Such were spots of necrosis, sieve-like rarefaction, punctiform haemorrhages, oedema, and swelling of axons. These lesions were produced by the sudden raising of the intraspinal pressure caused by the passage of the missiles through the intraspinal space or by a general concussion effect. They were well marked in cases of concussion without external wound.

After discussing the mode of production of the direct injury, he said that it seemed to him impossible that a bullet could cross the spinal canal without causing the most severe and irreparable of transverse lesions, and he argued that in all cases in which relative or complete recovery occurred the lesion had been indirect—either an impact lesion or due to the indriving of bone. Probably the bullet was most frequently deflected by the bony wall and seldom traversed the canal. The passage of a high-velocity bullet in the immediate vicinity of the spinal canal or the impact of a projectile upon the bones forming the canal might cause lesions of the cord though the walls themselves remained intact. The damage to the cord produced in this way by indirect injury varied from the most severe with symptoms of a total transverse lesion with no recovery to the slightest with complete recovery.

Concussion Lesions.

Concussion lesions might occur from the bursting of high explosive shells when the back was turned towards the force of the explosion without the production of an external wound, lesion of the bones, or even bruising of the soft tissues. It was possible to conceive that when severe lesions had been caused in this way there had been such distortion of the spinal column as might produce a subluxation of the vertebrae which became immediately reduced, but not before it had severely compressed the cord. There was, however, no evidence of such a subluxation, and the lesions must be regarded as due to impact. In his own cases and in others seen the lesions had been in the lower dorsal region.

Root Lesions.

Sometimes the lesions produced by projectiles affected the spinal roots after they had left the thecal space to a much greater extent than the cord or thecal contents. This seemed to be the case when there was much fracture and crushing of the bone, especially in the region of the transverse processes. There was usually much swelling and oedema in the damaged area. Such root lesions were not entirely due to direct injury; they might result from

subperiosteal haemorrhages and periosteal swelling which strangled the roots in the intervertebral foramina, or from pachymeningeal haemorrhage.

Intrathecal Haemorrhage.

Blood effused into a free thecal space found its way into the lower part of the space around the cauda equina and lumbo-sacral enlargement, and, if massive in quantity, might distend that space and cause pressure upon the roots and epiconus, and ultimately completely destroy by pressure and evascularization the cauda equina, and perhaps also the lumbar enlargement. Small effusions might cause local signs of nerve root injury. A severe condition of this kind might resemble a complete lesion of the cauda equina or lumbo-sacral enlargement. Lesser conditions might cause signs difficult of explanation unless the possibility of intrathecal haemorrhage were borne in mind.

Total Necrosis.

Total necrosis of the distal segment of the spinal cord was found in one patient. The signs were those of a complete transverse lesion at the level of the third dorsal segment, and the patient survived for three months. The most plausible explanation for such lesions was a spreading thrombosis throughout the blood vessels of the distal segment.

Reflex Action.

It was usually held that the initial condition of reflex action after the occurrence of severe lesion of the cord was that there was complete loss of both jerks and superficial reflexes, or that, if the loss was not complete, the only sign of reflex action left was a feeble flexor response of the toes; and that the early presence of the extensor response, or its early return, indicated that the lesion was not complete and was of good import. He had seen one case, fatal on the fourth day, with persistent extensor plantar response which negated this view. There were four consecutive stages in the condition of the plantar reflexes following transverse lesion of the cord: (1) An initial extensor response; (2) either complete absence of reflex or a reduced flexion reflex; (3) extensor response; (4) normal flexion reflex which returned when recovery was complete. He had repeatedly observed these successive changes, and considered that the plantar reflex was an index of the severity of the damage and an important early indication as to recovery. His observations led him to support Lieutenant-Colonel Gordon Holmes's view that the "reduced flexor response" was a unisegmental reflex involving the first sacral segment only. Another important point which had been brought out by recent experiences was that the influence of the higher nervous system upon the reflex action and muscle tone of the cord was strictly homolateral.

Contracture.

Three conditions of contracture of the feet occurred in these paraplegic cases: (1) The dropped foot with retracted toes—pes cavus; (2) the retracted foot with retracted toes—the calcaneus position was often extreme, the ankle-jerk was always lost and the anterior tibial jerk marked, an extensor plantar reflex was always present; (3) the dropped foot with dropped toes, with either absent or reduced flexor response. He considered that the dropped foot with dropped toes indicated a more complete transverse lesion. The calcaneus position was a very remarkable phenomenon, and had always persisted in such cases as he had met with.

Speaking of the ultimate condition of the paralysed region in cases of total transverse lesion, he suggested that "isolation dystrophy" might reach such a point that no signs of activity of the lumbar enlargement remained. To "paralysis in extension" and "paralysis in flexion" he thought might be added a third type—complete flaccid paralysis—from which the other types developed, and to which they returned when there was an increasing lesion or from long-standing isolation of the distal segment.

SURGICAL ASPECTS.

Lieutenant-Colonel DONALD ARMOUR said that the cases met with fell into two main classes: (1) Those in which the function of the cord was not interfered with; (2) those in which there was interference with function with or without damage to the vertebral column. Later effects—such as arose from inflammation, and as adhesions, serous

cysts, blood clot, continual suppuration, etc.—had also to be considered. The most frequent cause of cord injury was a driving in of fragments of bone. The lesions varied from concussion to extensive injury, diffuse and irregular in distribution, with a tendency to diminish gradually from the site of the disturbance. The point of chief importance was whether it was possible to recognize clinically the nature or extent of the damage. X rays were most unreliable in this respect. They might fail to reveal a bony injury when it was present, and never showed the full extent of the injury within the spinal canal.

With regard to operative procedure, three questions arose: (1) Would any benefit accrue? (2) Would life be endangered by it? (3) Might the patient be made worse by the operation? In practised hands he did not think that operative treatment should add materially to the risk.

The level of the lesion, as determined by diagnostic methods, did not correspond to the level of the vertebral damage, and therefore a wide area of the cord should be exposed. The dura, if intact, should not be opened if sepsis were present, and drainage should be employed. A contraindication to operation was a septic condition of the kidney or bladder. If the intercostal muscles were paralysed, this undoubtedly added to the danger of the operation, but such danger might be successfully guarded against by a skilled anaesthetist. An operation was indicated to remove pressure by bony fragments, haemorrhage, oedema, secondary thickening, etc. Since there was no sure means of distinguishing between concussion and actual gross damage, he thought that if any doubt existed, the patient should be given the benefit of the chance of relief by surgery.

DISCUSSION.

Dr. LEONARD GUTHRIE, speaking of the prognosis in transverse lesions of the cord, said that in cases of complete transverse lesion certain familiar symptoms arose; similar symptoms resulted merely from spinal shock. Spinal shock could not be excluded within three months of the injury. In certain cases in which an operation had been performed it had been reported that the cord was disintegrated and pulped, and yet return of function followed. Any return of function was an indication that the cord had not been completely destroyed, as was supposed. He referred to a case in which some return of power and of reflexes took place a year and three months after the cord was said to have been destroyed. With spinal shock, first flaccid paralysis, and then paralysis in extension or in flexion might follow. Paralysis in extension was an indication of a lesion less severe than in paralysis in flexion. Flexion which had become permanent was distinct from that occurring with stimulation, and represented a cadaveric position or a return to the fetal condition. Great caution should be exercised in accepting the view that a complete transverse lesion of the cord had existed. He then recorded certain anomalous cases in which the effects of lesions seemed to indicate the existence of separate sensory paths for sensations which are generally considered to take the same course.

Captain E. ADAMS, speaking from experiences at King George and St. Thomas's Hospitals, referred to 14 cases with positive evidence of damage of nerve tissue. In all there were destruction of nerve cells, haemorrhage and concussion. Three ended fatally, 2 from urinary sepsis and 1 from bronchopneumonia; in 3 there had been no improvement, but of 1 it was too early to speak definitely; in 8 substantial progress had been noted. In such cases he thought that bedsores and catheters must account for some fatalities. The former danger had been greatly lessened by more skilled nursing, but he questioned whether it was right to hand over cases of spinal cord damage to male nurses for regular catheterization. The same view seemed to be suggested by those who in France had resorted to suprapubic cystotomy. Relief of pressure on the cord was the chief aim of surgery. In all fatal cases exploration of the cord showed it to have been severely pulped. In those which improved the cord was softened in one. It was a matter for consideration whether the neural arches should be removed in all cases. In the majority he thought that exploration was not only justifiable but indicated. He preferred to wait until two or three weeks after the wounds had healed.

Captain E. FARQUHAR BUZZARD said that he was in almost complete agreement with Colonel Armour and Captain Adams. In all cases in which an operation was done to determine whether there were pressure on the cord it was not wise to rest satisfied with the mere removal of a foreign body without proper laminectomy. Paraplegic symptoms sometimes came on after a considerable interval. He related such a case in which a foreign body had been removed without laminectomy. The condition had greatly improved after rest. More rest was required after an injury in the cervical region than after an injury elsewhere in the cord. A troublesome sequel to cord lesions was spasticity. In the treatment of this the education of the patient to enable him to overcome the contracture was important. Electric treatment and massage possibly did more harm than good.

Major NEWTON PITT had found that the results of laminectomy were generally very disappointing; it was therefore very difficult to know when to insist on its performance. In the treatment of the cystitis he had been impressed by the improvement which followed suprapubic cystostomy in two cases. Many anomalies were met with in the reflexes. The imperfect flexor plantar response was very interesting, as also was the variability of the plantar responses. He had seen a spastic condition of the legs with flexor plantar response in some cases and considerable divergences in the great and little toe responses on each side, and in that of the tensor vaginae femoris. The etiology of these variations needed more elucidation. Pyrexia occurred in two cases with marked spasticity and flexion of the limbs when extension was applied and disappeared when this was discontinued.

Dr. S. A. K. WILSON referred particularly to so-called cases of concussion of the cord. One case was that of a youth who was advancing when a shell burst ten yards in front of him but without hitting him. He fell down on to soft ground with sudden abdominal pain, followed by involuntary defaecation and loss of power and sensation below the waist. The symptoms were those of a transverse lesion at the level of the ninth dorsal segment. He had gradually improved. The nature of such conditions was undetermined; possibly they might arise from sudden "evascularization" of the cord. He also recounted a case in which symptoms came on after a considerable interval when the patient was thought to have got well. Three months after the injury the patient had suddenly noticed that he could not feel the coins in his pocket, and loss of sensation was detected in his right arm and leg. The symptoms cleared up after two months' rest.

Lieutenant-Colonel P. SARGENT agreed that when any doubt existed the patient should have the benefit of an exploratory operation; it was not a difficult or dangerous procedure. It would reveal conditions not recognizable by neurological methods or by x rays. It was difficult to decide when to operate in the early stages. The question of nursing had to be considered, and again, if the condition seemed almost hopeless, an operation might preclude the possibility of sending the patient home alive to his relatives. All that an operation could do was to relieve pressure, and the earlier that was done the better. In certain cases the spinal cord was swollen, particularly in the cervical region. Many such cases recovered spontaneously and progressed satisfactorily, but it was open to question whether a simple incision into the cord would not assist in recovery and avoid further destruction. The chief difficulty in recent cases was sepsis, which was often a deterrent.

FASTING TREATMENT FOR DIABETES.

At a meeting of the Hunterian Society on March 8th, when the President, Mr. W. H. KELSON, was in the chair, Dr. W. LANGDON BROWN, in a paper on the treatment of diabetes by fasting, said that three recent methods of investigation had been of great assistance in diabetes: (1) The estimation of the blood sugar, which had shown that, whereas in the large majority of cases of clinical diabetes there was hyperglycaemia, in a few, usually mild, cases the blood sugar was below normal; the blood, however, in many of these latter cases of "renal" glycosuria developed hyperglycaemia later on. (2) The so-called pancreatic-diastase reaction, which had shown that the amount of diastase in the urine was subnormal in nephritis, moderately raised in chronic pancreatitis, and

very greatly increased in acute pancreatitis, with blocking of the ducts. The reaction was of value in diagnosing cases of glycosuria of pancreatic origin. (3) The estimation of the alveolar CO_2 had often proved of use in foretelling the onset of coma. Obvious errors of internal secretion were not often met with, but sugar in the urine might occur in the following conditions:

1. *Pancreatic Insufficiency.*—In this case there would be hunger pain and other symptoms of hyperchlorhydria. Very often fatty diarrhoea, and certainly increased diastase reaction.

2. *Thyroid Over-action.*

3. *Suprarenal Over-action.*—Many of the cases of glycosuria in later life, with raised blood pressure, were probably of this type.

4. *Pituitary Over-action.*

The disease was formerly looked upon as due to a disorder of carbohydrate metabolism; it was now recognized that such facts as the presence of oxybutyric and other acids, and the varying amount of ammonia in the urine, indicated that the metabolism of fats and proteins was implicated as well. In order to standardize results he used the test diet containing 100 grams of carbohydrates and 108 grams of proteins. This was capable of producing 164 grams of carbohydrates, and the proportion of this excreted as glucose gave the "coefficient of excretion" in any particular case. The essential principle of the new treatment was fasting. While fasting, in an ordinary person, would occasion a rise in the diacetic acid, in a diabetic it was followed by a diminution. The method of treatment was a complete fast for forty-eight hours followed by von Noorden's "vegetable egg" diet for forty-eight hours. Protein was then added cautiously during the ensuing days; this formed the "ladder diet" stage. After a fortnight the fast routine might be repeated in suitable cases. The aim was finally to reach a "balanced diet" in which a small proportion of carbohydrates found a place. The usual diabetic diet contained far too much protein, and this excess often predisposed to acidosis. Diabetics were not intolerant of the carbohydrates equally; laevulose was much more readily assimilated than most. As artichokes contained inulin, which on digestion gave rise to laevulose, they might be made the first addition to the diet. Others, readily assimilable, were potatoes, baked apples, milk in small quantities, and even green peas. By making use of the fast routine and the balanced diet far more satisfactory results were obtained than by other dietetic methods.

Reviews.

EXERCISE IN EDUCATION AND MEDICINE.

WE noticed the first edition of Dr. R. T. MCKENZIE'S *Exercise in Education and Medicine*,¹ and we now welcome the appearance of a second edition of a book which is certain to be valued by all who are interested in the subject, either as educationists or as physicians. It contains a historical review of the progress of physical education in many parts of the civilized world, even in such countries as China and Manila and among the North American Indians. In the United States this branch of education has received special attention, and the provision of gymnasiums and playgrounds forms an outstanding feature of municipal work. In the universities which have grown up so abundantly in the various States of the Union during the last generation the need for the physical training of students has been not only recognized but even to some extent over-emphasized, for we are not sure that we agree with the author's statement that this training increases the powers of self-preservation and efficiency and teaches a graceful carriage and "those social and moral qualities which can be cultivated so well in no other way." The athlete may be a ruffian and a bully. Record breaking and the desire to win games by any means should be sternly repressed, as only when his skill is associated with a chivalrous character does the athlete become admirable. An excellent feature of the system followed by American teachers of physical education is the "floor talks," or short addresses of about ten minutes' duration on such subjects as the causes of disease, the

carriers of infection, cleanliness, the dangers of dirty uniforms and soiled towels, on diet, exercises, bathing, alcohol, tobacco, and venereal disease. It is hardly possible to over-estimate the good that may be done by a teacher who can deal with subjects such as these in a manner to secure the attention and interest of his hearers.

In his remarks about the athletic education of girls, the author says that though they do not appear to have a natural taste for regular exercises, there has been improvement in this respect in recent years. The exercises followed should not be the same as those for boys, but should be adapted to suit the special character of girls. It is particularly desirable that the co-operative spirit should be encouraged among them by means of "team games," and that there should be plenty of outdoor exercises to promote nervous stability. No comparison in records should be made between men and women; in most exercises women only attain to about two-thirds of the standards reached by men, but in dancing, swimming, skating, and fencing they reach much nearer the male level.

The later part of the book gives a detailed account of the therapeutic use of exercises, and here as elsewhere it is abundantly illustrated by drawings and photographs.

PUBLIC HEALTH.

MR. MATTHEWS, in his book on *Refuse Disposal*,² describes the various methods employed in collecting and disposing of the refuse of towns and cities. The subject is pregnant with interest to bodies concerned in maintaining and improving public health. Efficient and economic scavenging demands increasing attention from sanitary authorities, and the full and reliable information contained in this book will undoubtedly be helpful to authorities about to adjust their equipment to existing necessity. The description of removal methods shows the great development which has taken place in the type of vehicle for removal purposes. The immense advantages, from a sanitary point of view, such a removal car as the Fram possesses, as compared with the uncovered dust cart too commonly used at the present time, are apparent. Mr. Matthews, no doubt intentionally, deals briefly with all methods of disposing of organically charged matter, excepting destruction, since he regards it as the only method of disposal which safeguards the public health. The various types of destructor are described and are fully illustrated by photographs and plans. The claims of the smaller type of destructor are of especial interest at present to those in charge of military stations, where the amount of refuse per head of population is considerable, and where speedy and safe disposal is an urgent necessity.

*The Colchester Oyster Fishery*³ is an interesting little book devoted to description of an industry which dates from a very early age. The oyster was recognized as a delicacy before the time of the Roman Empire, and its value as an article of invalid dietary is admitted. It is of the greatest importance, therefore, that the cultivation of oysters should be conducted under conditions which ensure that the marketed product is wholesome. Where circumstances are less favourable than those which obtain in the Pyfleet oyster beds, risks attendant on sewage contamination may render the product a source of danger. It is the indisputable right of the consumer to be safeguarded against such a menace, and any dealer who markets oysters from sewage-contaminated waters incurs grave responsibilities. Mr. LAYE has demonstrated that the geographical position of the Colchester fisheries is such that contamination under existing conditions is well-nigh impossible, and his book has rendered the industry with which he deals a notable service.

PLAGUE IN ART.

No disease holds so large a place in art and literature as plague, for although there are several which claim a heavier tribute of human lives, plague, by the swiftness

³ *The Colchester Oyster Fishery*. By H. Laye, F.S.A., Chairman of the Colne Fishery Board, Colchester. Published by the authority of the Colne Fishery Board. 1916. (Cr. 8vo, pp. 92; 41 illustrations. 2s. 6d. net.)

with which it has spread through nations and over continents and the upheavals of the social system which it has caused, has always struck a special terror into the hearts of men. In their fear afflicted communities sought for metaphysical aid, and when the day of deliverance came their gratitude and their wish to propitiate the anger of heaven found expression in the building of temples and churches, in the erection of statues, and in pictures, medals, and votive offerings of various kinds. While artists in different ages have found inspiration in plague, writers of fiction have described its visitations and poets have sung its horrors. Historians who have not thought other infectious diseases or general problems of hygiene worth notice have chronicled epidemics of plague and have discussed their economic, social, moral, and political effects. On the memorials of these visitations found in architecture, sculpture, painting, and literature, Dr. RAYMOND CRAWFORD based the Fitz-Patrick Lectures delivered by him before the Royal College of Physicians of London in 1912. He has since embodied the substance of them, with considerable expansions, in a handsome volume in which he gives a masterly review of the whole subject from the earliest records of pestilence down to the end of the eighteenth century.⁴

Among the earliest votive offerings were representations of the parts affected by the disease, such as the golden images of "emerods" sent back by the Philistines with the Ark of the Covenant which they had carried off from the Israelites and placed in the temple of their own god, Dagon. Ancient Rome was sorely afflicted by pestilence, and in the closing days of the third century before Christ the magistrates sought aid at Epidauras, the famous shrine of healing. The serpent of Aesculapius was sent and a temple dedicated to the god was built on the Isola Tiberina. In recent excavations many votive offerings have been found on its site. In Christian times representations of saints whose names were for any reason associated with plague figure largely among the adornments of churches. Saint Sebastian was a favourite subject, probably because his was one of the few nude figures allowed to Christian art in Italy, Switzerland, Southern Germany, and South-Eastern France. Statues and pictures of St. Roch, who is usually depicted with a bubo in the left groin, are also very common.

Dr. Crawford gives an interesting account of the effects of the Black Death on the literature, art, and architecture of England. Throughout the Middle Ages plague was endemic in central and southern Europe, and dances of death, plague banners, votive and commemorative paintings, and representations of plague scenes bear witness to the deep impression which it made on the minds of men. These epidemics also gave a strong impetus to the production of mystery and miracle plays.

Among the historians of pestilence the first place must be given to Thucydides, but Dr. Crawford, from a critical study of his description of the great pestilence of Athens, concludes that the disease was not oriental plague but typhus fever. Of plague the most striking records in literature are found in two works of fiction. In his *Promessi Spesi* Manzoni gave an account of the terrible outbreak at Milan in 1630, which can never be forgotten by any one who has read it, and Daniel Defoe's *Journal of the Plague Year* was accepted by Mead as the authentic record of an eye-witness of the appalling visitation which made London a city of death in 1665. Dr. Crawford, however, thinks that Defoe used materials collected by him for a record of the plague of Marseilles in 1720, and transferred the scene to London. Samuel Pepys, from his own observations, painted a truer picture.

Dr. Crawford's book is illustrated with excellent photographs of the most famous pictures dealing with pestilence in the churches and galleries of Europe. It is a monument of learning and industry, and is written in a style which makes it worthy to rank among the best contributions to the literature of plague. It is a pity, however, that a work so full of varied matter should have neither index nor table of contents.

⁴ *Plague and Pestilence in Literature and Art.* By Raymond Crawford, M.A., M.D. Oxon., F.R.C.P. Oxford: The Clarendon Press, 1914. (Roy. 8vo, pp. 230; 31 plates. 12s. 6d. net.)

NOTES ON BOOKS.

MISS A. E. POPE has written a number of books for the instruction of nurses. Her volume of *Anatomy and Physiology for Nurses*⁶ deals mainly with elementary physiology. Of this it contains an ambitious and up-to-date summary which, one would think, is bound to give a strange idea of the science to any one not possessing a solid knowledge of its elements. There are numerous diagrammatic illustrations; many of these, adapted from drawings of microscopical preparations, would gain by the addition of figures to show the scale of magnification under which they are reproduced. In Fig. 109 the inferior thyroid veins are wrongly labelled as the "brachio-cephalic vein." Miss Pope's *Quiz Book of Nursing*⁶ contains a series of questions and answers designed for the use of nurses who teach and nurses who study under them; it is designed to offer the information essential from the nursing standpoint. It is divided into chapters dealing with the ward, the general and special care of patients, treatment, medicine, diet, disease, and so forth. Special chapters at the end are given to expositions of the duties of visiting nurses, hospital planning, and hospital book-keeping. Much of the book is excellent; but when the author states (p. 384) that a tumbler contains no more than from 6 to 8 fluid ounces, one is tempted to think she has forgotten for a moment that America is the home of the long drink.

Dr. ELIZABETH BUNDY'S *Textbook of Anatomy and Physiology*,⁷ now in its third edition, contains the quantum of knowledge thought suitable for the pupils in training schools and other educational establishments. The type and spelling are American; the illustrations have been selected from such standard works as those of Morris, Deaver, and others. Dr. Bundy's book appears to have begun life as an "Anatomy for Nurses," and contains comparatively little physiology. Occasionally it divagates into pathology; thus on page 338 we read that "Cataract is a thickening of the lens. . . ."

Dr. N. C. FLETCHER'S *Compendium of Aids to Home Nursing*⁸ is an attempt to express the wisdom of the well-trained nurse in the form of memoriae technicae and tabulation, and is based on the author's Polytechnic lectures. It is complete and concise, and should be of service to those who learn best with the help of mnemonic aids.

The Child: His Nature and Nurture,⁹ by Dr. W. B. DRUMMOND, covers a good deal of ground that has been touched on by other authors. The history and comparison of the Froebel and Montessori methods of education is of considerable interest, and will be welcomed by many teachers of young children.

There are some good points in *What Every Mother Should Know*,¹⁰ by C. G. KERLEY, but we cannot agree with the author on the proportions of milk advised for infants of from 3 to 10 days old. Three ounces of milk to seventeen ounces of water and lime water is too dilute a food for the average baby, nor do we like the suggestion that the food for twenty-four hours be mixed at one time.

⁶ *Textbook of Anatomy and Physiology for Nurses* By A. E. Pope. Second edition. New York and London: G. P. Putnam's Sons, 1915. (Cr. 8vo, pp. 604; 137 figures. 1.75 dols. net.)

⁶ *A Quiz Book of Nursing for Teachers and Students.* By A. E. Pope and T. A. Pope. Same publishers. (Cr. 8vo, pp. 499; 5 figures. 1.75 dols. net.)

⁷ *Textbook of Anatomy and Physiology for Training Schools and other Educational Institutions.* By Elizabeth R. Bundy, M.D. Third edition. London: J. and A. Churchill, 1915. (Med. 8vo, pp. 423; 233 figures. 8s. 6d. net.)

⁸ *A Compendium of Aids to Home Nursing (Home Nursing Simplified and Tabulated).* By N. Corbet Fletcher, B.A., M.B., B.C. Cantab. London: J. Bale, Sons, and Danielsson, Ltd. 1915. (4½ by 5 in., pp. 163. 6d. net.)

⁹ *The Child: His Nature and Nurture.* By W. B. Drummond, M.B., C.M., F.R.C.P. Edin. London and Toronto: J. M. Dent and sons, Ltd. 1915. (Cr. 8vo, pp. 223; 11 illustrations. 2s. 6d. net.)

MEDICINAL AND DIETETIC PREPARATIONS.

Chloramine-T Disinfectant.

IN the paper on the antiseptic action of hypochlorites, published in the JOURNAL of December 4th, 1915, Dr. H. D. Dakin showed that probably it was conditioned by the formation of chloramines rather than by any decomposition with liberation of oxygen. In another paper, published in the JOURNAL of January 29th, 1916, by Dr. Dakin, Professor Cohen and Dr. Kenyon, it was pointed out that, as it was believed that the antiseptic action of hypochlorites was

due to their capacity for attacking proteins and related bodies, with formation of substances containing chloramine linked to nitrogen, so chloramine appeared to act also, for when brought into contact with proteins such as blood serum it parted with its chlorine, which attached itself to the nitrogen of the second substance. When the hypochlorites act upon free ammonia the simplest chloramine, NH_2Cl , is produced, and by reaction on other bodies other more complicated chloramines are formed. After testing a number of chloramines, they selected para-toluene-sodium-sulphochloramide. This substance has been used with results so satisfactory that a considerable demand has arisen for it, and the substance was put upon the market under another name a short time ago.¹ Boots Pure Drug Company now inform us that they prepare para-toluene-sodium-sulphochloramide, and can supply it under the name "Chloramine-T," suggested by Dakin and his fellow-workers, in powder or in the form of compressed tablets. The powder is fine, white, and flaky, with a faint chlorous odour. It is freely soluble in water, so that it is easy to make a 3 or 4 per cent. solution, which is the strength recommended for wounds. A weaker solution (1 to 2 per cent.) has been highly praised in the treatment of wounds and infections of the mouth and throat, and Mr. A. Edmunds, who had used it at Malta, said during the discussion at the Harveian Society after the reading of Sir Berkeley Moynihan's address on February 24th that as the supply then available to him was small he had reserved it for such cases. Sir Berkeley Moynihan mentioned in his paper published in the JOURNAL of March 4th that chloramine gauze prepared by Dr. Dakin had been used in Leeds and elsewhere in the Northern Command with results which justified the belief that it was the best method so far introduced for checking and controlling the development of infective processes. Messrs. Boots have sent us a sample of gauze, which seems to be very well prepared. The chloramine is entangled in the meshes of the gauze, which in consequence has a rather pungent odour when the package is first opened. With reference to the powder, Messrs. Boots inform us that at the price they are charging a 2 per cent. solution costs 3d. a lb. and a 4 per cent. solution therefore 6d. a lb., as compared with 10d. a lb., the present price of hydrogen peroxide (10 volumes). The germicidal action of Chloramine-T, molecule for molecule, is about four times as great as that of sodium hypochlorite. The prices charged by Messrs. Boots are: For the powder, 1s. an oz.; 4 oz. for 3s. 6d.; 1 lb., 12s. 6d. Bottles of 100 tablets (8.75 grains each), 4s. 6d.; bottles of 12 tablets of 43.7 grains each, 2s. 8d. The price of the gauze, containing approximately 35 per cent. Chloramine-T, is 1s. a roll. The prices in all cases are post free.

MEDICAL AND SURGICAL APPLIANCES.

Axis Tractor Adaptable to any Obstetric Forceps.

DR. R. I. CUMING (West Brompton) has designed a contrivance to obviate the bulkiness, complexity, and expense of a special instrument; it can be fixed on the handle of a forceps of any pattern and applied even when efficient help is not at hand. He has used it, he states,

in many difficult cases, and it has never failed him. The instrument consists (1) of a traction handle with a swivel, allowing the head to rotate freely, connected with (2) an indicator, rounded at the free end, which shows the direction of

traction. (3) A sliding bar, furnished with a screw and thumb-piece, allows of the instrument being fitted to any forceps and of the direction of traction being adapted to any pelvis. The underside of the sliding bar is fitted with (4) a screw arrangement, which holds the instrument to the forceps and at the same time regulates the amount of pressure on the head. The appliance is made by Messrs. Salt and Son, Birmingham.

¹ BRITISH MEDICAL JOURNAL, February 19th, p. 289.

THE school of massage for blinded soldiers founded in 1915 by Madame A. Léopold-Kahn at the convalescent home at Reuilly has received official sanction.

ELECTROLYTIC HYPOCHLORITE FOR HOSPITAL SHIPS.

A REPORT to the Medical Research Committee¹ on the use of sodium hypochlorite prepared by the electrolysis of sea water for disinfecting and antiseptic purposes on ship-board, especially in hospital ships, has been made by Drs. H. D. Dakin and H. G. Carlisle, and will be read with much interest, because it is important both in its scientific and practical aspects. The report mentions the well-known Hermite process for the sterilization of sewage by electrolytic hypochlorite, introduced about 1893, and the use of electrolytic hypochlorite for general disinfection by several sanitary authorities, notably at Poplar, and the valuable results obtained through its use in the plague epidemic in Glasgow in 1901.

Installation on H.M.H.S. "Aquitania."

The report contains a description of apparatus installed on H.M.H.S. *Aquitania*, and is illustrated by scale drawings which would make it possible for any combination of doctor and engineer to introduce the method into any ship in which its use seems advisable. The electrolyzer consists of a rectangular box of teak or cedar bolted together and divided into twenty or twenty-five cells by means of carbon plates placed parallel to one another. Great care must be taken in the selection of the carbon plates, and a particular kind of graphite is recommended. Two wires leading the ship's current (100 to 110 volts direct current) are suitably connected through a switch with the electrolyzer, which, to ensure even distribution of current, is provided with a copper plate attached to the four binding screws at each end. If alternating current only is available, it must be transformed. If the voltage be 200 to 220, two electrolyzers can be placed in series. Thanks are expressed to Dr. Edward Hopkinson, of Messrs. Mather and Platt of Manchester, for his assistance in constructing a practical and efficient apparatus, and apparently that firm is prepared to provide electrolyzers.

Strength of Solution.

When using ordinary sea water it is inadvisable to continue electrolysis for more than ten minutes. In that time, with a current of 60 to 75 amperes at 110 volts, a solution will be obtained containing usually a little less than 4 parts per 1,000 of sodium hypochlorite or available chlorine. For most purposes it is advantageous to limit the electrolysis to five minutes, and at the end of that time the solution will contain from 2 to 2.7 parts per 1,000 of sodium hypochlorite or available chlorine. For swabbing floors, walls, latrines, etc., this may be diluted with an equal part of water. Comparative experiments upon the bacteriological conditions of floors before treatment, after treatment with salt water, and after treatment with hypochlorite at 1 in 1,000 showed a large reduction by the use of plain sea water, but a huge reduction after the application of the hypochlorite.

Use in Wards.

The results of the free use of hypochlorite in the wards were most gratifying. The general opinion after the experience of two voyages to the Mediterranean was strongly in favour of the hypochlorite as contrasted with phenolic disinfectants. In the typhoid and dysentery wards the results were particularly striking and the absence of odour most marked. In these wards the hypochlorite disinfectant was placed in the bedpans before use. The most important effect, however, had been the large reduction in secondary infection occurring among the ship's staff. While it was not considered that this fortunate result was exclusively due to the hypochlorite, it was generally considered among competent observers that its introduction had been an important cause of the improvement.

Drinking Water.

The hypochlorite had also been used for the purification of the ship's drinking water. About 1 in 1,000,000 was sufficient for all ordinary purposes, and the instability of electrolytic hypochlorite was so great that after three or four hours all traces of chlorine disappeared. On the average about 25 per cent. of the hypochlorite disappeared

¹ Journal of the Royal Army Medical Corps, February, 1916.

in twenty-four hours when the solution was stored in shallow tubs, but in covered vats the rate was materially less.

Surgical Use.

Electrolytic hypochlorite for surgical use should not be kept for more than twenty-four to forty-eight hours, but it can be so readily and cheaply prepared that this is not a matter of consequence. As it is free from excess of alkali and reacts faintly acid to phenolphthalein, it was considered that it would be suitable for surgical use, and it was also thought that the presence of the sodium and magnesium salts in the sea water might have a beneficial lymphagogic action similar to that observed in the hypertonic salt solution described by Sir Almroth Wright. It was believed to have been first used for surgical purposes on the French ship *Charles Roux*, and Drs. Dakin and Carlisle were able by the kindness of the P.M.O., Dr. Heitz-Boyer, to spend several days on the ship and to see the solution employed on about 200 purely surgical cases, most of them from Cape Helles, where the wounds were well known to be badly infected. The idea of using the electrolytic hypochlorite on the *Aquitania* was welcomed by Lieutenant-Colonel R. H. Fuhr, D.S.O., R.A.M.C., and it was used in a number of suppurating injuries, many of them originally due to frost-bite. The clinical results were similar to those observed with the hypochlorite prepared from bleaching powder, as originally described by Dr. Dakin in this JOURNAL on August 28th, 1915. A slightly lower concentration was preferred, and for this purpose the sea water, electrolyzed for five minutes, using about 65 to 70 ampères at 110 volts, and therefore containing from 2 to 2.7 parts per 1,000 of sodium hypochlorite, was found a good concentration for general use in surgery.

Laundry.

The solution was also useful in the laundries. In some of the French boats it was used for soaking undyed cotton and linen; it acted as a disinfectant, and had also a marked action in loosening dirt and in bleaching. The solution should be well diluted so as to contain about 0.12 to 0.25 per 1,000 of available chlorine.

Swimming Baths and Harbours.

A similar solution has been used for purifying the water of the swimming baths at Bow and Poplar, and an experiment made in the swimming bath on the *Aquitania* showed that the addition of electrolyzed sea water in the proportion of 1 in 2,000,000 of available chlorine caused a reduction in the number of organisms in two hours from 2,000 to 200 per c.c.m. It is suggested that the solution may find an important application in the treatment of the heavily infected salt water frequently found in harbours and ports, particularly those of the Mediterranean, where the tidal purification is slight. Observations were also made as to the effect of the solution on various structural materials.

Effects on Metals, etc.

Clean iron and steel were attacked rapidly by 1 in 1,000; copper more slowly; brass still more slowly; and aluminium, zinc, nickel, and tin scarcely at all under the conditions of the experiments. Lead was the most resistant of all the metals tested. Tin plate, nickel plate, and galvanized iron were not appreciably attacked if the plating was intact. Wood took up a certain amount, but in no case was significant damage done. Wooden tubs containing strong hypochlorite solutions for long periods developed a soft whitish deposit, but if this was not scraped off further action soon ceased. Painted wood and metal proved to be very resistant. None of the floor surfaces in the wards on board ship showed significant damage, but the solution dried rather slowly on damp days on linoleum. Speaking generally, it may be said that no significant damage to ship structures was observed after two months' use.

An Expert Opinion.

In some remarks attached to the report Lieutenant-Colonel Fuhr says that for the purification of drinking water the method was quick, simple, and very easily

worked, giving a clear potable water with no appreciable taste or smell if the mixing was thorough. With regard to its use in surgery, he says that he has been much impressed by the results, and by the fact that on changing gauze dressings they readily peel off without pain or bleeding of the granulations. Some considered that the chemically made balanced solution was less irritating, but this, in Colonel Fuhr's opinion, was a matter of dilution and increased frequency of dressing. For sanitary purposes it was the best, cheapest, and most easily applied method available, and as a deodorant it was invaluable. The *Aquitania*, accommodating more than the seven largest London hospitals, had given him full opportunity for forming a considered opinion, particularly as large numbers of dysentery and paratyphoid cases had been carried. The confinement of approximately 4,000 patients in a limited space rendered essential most stringent sanitary precautions, and Colonel Fuhr states that he has satisfied himself that for efficiency, economy, and utility, electrolytic hypochlorite is very essential for hospital ships.

DR. GODLEWSKI states in the *Press médicale* (February 3rd) that he has taken blood from sucklings for haemoculture and Wassermann's reaction, and more recently from military patients, without ever missing a vein, never making a *saignée blanche* as Dupuytren would say. Godlewski makes use of the fact that a vein can be displaced laterally, but only to a limited degree. A vein in the bend of the elbow being made prominent, the needle of a hypodermic syringe or any other suitable needle is thrust into the skin on one side of the vein—on the concave side if the vein be somewhat curved. The needle pushes the vein away for from 2 to 5 mm., but then the limit of lateral displacement is attained, and the point will enter without fail. The needle must be passed almost parallel to the surface of the arm obliquely towards the vein and close under the skin, otherwise it is certain to pass behind the vein.

A SYMPOSIUM on leprosy was held on October 27th at a meeting of the Chicago Medical Society (*Journ. Amer. Med. Assoc.*, November 13th, 1915, p. 1753). The disease in North America is limited to a few foci. In 1815 a leprosy person from Normandy settled at Tracadie, in New Brunswick, and there has been leprosy in the district ever since. There is a lazarette containing 26 beds, but, as the result of partial segregation and better sanitary conditions, leprosy is rapidly diminishing, and few of the beds are now occupied. Scandinavian immigrants have introduced leprosy into Minnesota, eleven cases being detected in 1900. By 1903 no new cases were reported. Along the Mexican frontier a few cases are now under treatment; the patients seem all to be Mexicans. It is believed that there are about 100 lepers in New York and a few cases in Chicago, but in no instance did the disease arise in either place. Two well-known foci of leprosy in the United States are in Louisiana and Key West, Florida. In Louisiana, where leprosy is active, every effort is made to segregate lepers as completely as possible, public asylums of refuge being now provided for them. No such institutions appear to have been established elsewhere in the States, and the establishment of a national sanatorium for lepers is advocated.

THE *Revue Neurologique* is the official organ of the Paris Société de Neurologie. The number for November-December, 1915, which has recently appeared, is, like that of May-June, 1915, devoted entirely to war neurology. It forms a volume of 436 closely printed pages, containing original contributions on disturbances of vision due to lesions of the intracerebral optic paths and of the cortical visual sphere by Pierre Marie and Charles Chatelin; on nervous disturbances of reflex nature by J. Babinski and J. Froment; on the relation of trembling to emotional states by Gilbert Ballet; and others, besides abstracts of communications made to societies and papers in medical journals—French, English, Russian, and Italian—during the second half of 1915. A special feature is a review of the work of French military services of neurology. Summaries of some Austro-German papers are included. These are said to be "of little importance," but the editors state that they have thought it their duty to place at the service of humanity all scientific productions whatever be their source. The January issue of the *Edinburgh Review of Neurology and Psychiatry* is also devoted to the neurology of the war. It contains a report by Dr. A. Ninian Bruce of a case of disseminated sclerosis following exposure with long periods of remission, and fifty-two pages of abstracts.

SATURDAY, MARCH 25TH, 1916.

WOUNDS OF JAW AND FACE.

On the outbreak of war those whose daily work made them realize the calls the army and navy would make on the dental profession urged not only that dentists in large numbers would be needed for preventive dental treatment—treatment more especially designed to obviate the many and serious disabilities arising from septic teeth and want of teeth—but also that special attention should be paid to the difficult subject of repair after serious injury of the jaws and face. They remembered the disabilities, ranging from the loss of power to eat anything but soft food accompanying an ununited fracture of the mandible to the awful misery of such cases as that figured in Heath's *Injuries and Diseases of the Jaws*, in which the whole suborbital part of the face had been blown away by a shell. This occurred in the Crimean war and culminated in the suicide of the victim. They knew, too, that the dentist had not been idle in devising means to relieve the miseries of these unfortunates. Civil practice constantly provides a certain number of cases of direct injury, of necrosis, of resection for tumours, in which greater or lesser amounts of bone and soft parts are lost from the jaws and face; and the need had already produced the men to deal with it. Foremost of these was Claude Martin, a dentist of Lyons, who by lifelong study elucidated the main principles of the methods of combating cicatrization and of applying temporary and permanent substitution apparatus, even to the extent of artificially replacing an entire mandible. Further the surgeon had introduced bone grafting, skin grafting, improved methods of plastic operation, and above all, better ways of dealing with sepsis.

What may be called preventive dentistry, which in view of the numbers involved and of its influence on the general health of the soldier and sailor is the more important problem, has received very considerable and constantly increasing attention.

Colonel Lee, in his speech on the Army Estimates last week, said that at every clearing station along the whole front there is a well-qualified dental surgeon, well equipped with appliances. We may add that we understand that the French authorities have accepted the services of a corps of 1,000 dentists.

The dentists employed with the armies probably have plenty to do, and the treatment of wounds of the jaw is only a part of their duties. It is, however, a very important matter, and the need for special hospitals at the bases was early recognized in France; at the end of November, 1915, there were seven special centres—Paris, Lyons, Bordeaux, Marseilles, Montpellier, Bourges, and Clermont. Mr. H. Baldwin, President of the Odontological Section of the Royal Society of Medicine, in introducing the discussion on war injuries of the jaws and face, reported in our issue of March 11th (p. 375), said that in Paris the jaw cases were divided between the dental department of the American ambulance, a wing of the military hospital of the Val-de-Grâce, the dental school and Michelet Hospital, and a private hospital maintained by the

Comtesse de Grammont. The total number of beds provided in these four hospitals for jaw cases was about 1,000. The organization at Lyons under the general direction of Dr. A. Pont he described as wonderful. The central institution was installed in a large school building called the hospital for stomatology and bucco-facial prosthesis, and in that and five other hospitals beds were provided for 830 jaw cases. The beds in one hospital were reserved for jaw injuries complicated by wounds of the sinuses and ear, under the care of an experienced oto-rhino-laryngologist, as well as a stomatologist. Another was for jaw injuries complicated by wounds of the eyes, and had an ophthalmological service.

In England a start has been made in the Eastern Command, a special hospital having lately been organized at Norbury, where there are now collected about 130 jaw cases under the care of a specially selected dental surgeon. In one direction at least—the treatment of ununited fractures of the jaws—this specialization has already proved of value. We are sure that the military authorities in this country realize the great possibilities of relief the progress of dental and medical science has made available, and are aware that there is a very considerable number of dental surgeons willing and able to help.

In the same discussion Dr. Hotz, of the Paris centre, and Dr. Hayes, of the dental department of the American ambulance in Paris, said that the ultimate success of the treatment of such cases depends upon the building up and restoration of the jaws as a skeleton or framework upon which the final plastic operation can be made. When such cases came under specialist treatment late, though they might be cured of infection and their wounds healed, faces, he said, were distorted, mastication rendered impossible, and the fractured parts were not only displaced but consolidated, so that for reduction either a radical surgical operation, or long and tedious treatment with some special apparatus had become necessary. The moral that skilled dental intervention at the earliest possible moment is essential was supported by all subsequent speakers. Though it may be possible to make a general classification of jaw injuries, yet a specially made splint or apparatus is necessary for each one of such cases, because the teeth, which are used as *points d'appui* for the splints, are not in any two cases alike, and because when it comes to apparatus of replacement, such as false jaws, each case obviously stands alone. Only a skilled dentist can devise, make, fit, and fix these splints and apparatus. The teeth are very generally the groundwork on which the possibility of splint or permanent replacement apparatus rests. A judicious selection must at the outset be made of the remaining teeth and it may be advisable even to retain roots. Teeth likely to be of permanent value are scaled and perhaps filled; those of no value are extracted to aid in the general clearing up of sepsis. An excellent illustration of the expert use of roots was shown among the cases exhibited at the discussion alluded to. The issue between permanent disability and permanent usefulness of the jaw lay in the preservation of a molar root situated in the hinder fragment of the jaw. In this case the dental surgeon, Mr. W. Hern, was able to preserve the root and bring the case to a triumphant issue.

In those more serious cases in which bone grafting or replacement apparatus are contemplated, the patient should be in the hands of a dental surgeon at the earliest possible moment, while the parts are still accessible for taking impressions and noting the various necessary measurements. When vicious bony

union has taken place, when the original wounds of soft parts or the scars of plastic operations have cicatrized; the time for this work, the very foundation of the whole process, is past. Vicious bony union must now be broken afresh. Cicatrices must be stretched by long and painful effort, sometimes, as Claude Martin noted, extending over a year or more, and the result can never be as good as in cases taken in hand at once.

Special centres, each with a skilled dental surgeon and a general surgeon to undertake bone grafting or any necessary plastic operation, are needed, and it will often be necessary to keep ambulant cases under treatment for long periods, since recovery is often necessarily very protracted. In France this point is considered so important that lately, when in preparation for a large influx of wounded an order was sent out to evacuate all such cases as could walk, jaw cases were excepted unless they could be sent to a hospital similarly equipped.

FASTING TREATMENT FOR DIABETES.

ABOUT two years ago Dr. F. M. Allen of the Rockefeller Institute Hospital in New York introduced a new and apparently valuable method for the treatment of diabetes mellitus in certain of its stages. This has already been described briefly in this JOURNAL,¹ and was the subject of a paper read to the Hunterian Society recently by Dr. Langdon Brown (see p. 452). It consists in fasting or starvation, prolonged for several days together if necessary, followed by a period of very light diet. The treatment has been tried with success at the Massachusetts General Hospital, and an account of the experience gained with it there and details of the very various diets employed in these cases have recently been published by Dr. Hill and Miss Eckman.²

An outline of the treatment is as follows: The diabetic patient is kept on ordinary diet for two days after admission, in order that the severity of the disease may be determined. He is then starved, and no food is allowed save whisky and black coffee, one ounce of the former being exhibited every two hours from 7 a.m. to 7 p.m. This furnishes food to the value of about 800 calories, and serves to keep the patient more comfortable while he is being starved; if whisky is thought undesirable, bouillon or any clear soup may be given instead. Water may be taken *ad libitum*. If there is evidence of acidosis (strong acetone or diacetic reactions in the urine) a drachm or two of sodium bicarbonate may be administered every three hours; this, however, is rarely necessary, and there is no danger of producing diabetic coma by the starvation—a most important point brought out by Dr. Allen. The patient should be up and about during the period of starvation and not confined to bed. The starvation is continued until the urine shows no sugar; in the experience of Dr. Hill and Miss Eckman four days is the longest period of starvation that has been found necessary, but they know of obstinate cases that have been starved for as long as ten or eleven days. They say that the patients tolerate fasting remarkably well, and that they have not themselves seen any ill effects from it. The patient should be weighed daily, and a slight loss of weight is to be expected. It is, indeed, to be desired in the case of a fat patient, according to Dr. Allen. It is noted that starvation does not affect the urinary output of

diacetic acid and acetone in any definite way; if they were previously absent, the appearance of these bodies in the urine is not necessarily a cause for alarm.

When the urine has become free from sugar, as a result of the starvation, the patient is given at first a very light diet of vegetables, such as French beans, celery, spinach, cabbage, or asparagus, thrice boiled in water in order to remove as much of their digestible carbohydrate as possible, with tea or coffee to drink. It is very important that the diet should be raised and improved very gradually. Both the protein and carbohydrate in the food should be increased very slowly; the authors give full lists of the foodstuffs and diets they employ, and the food values and heat values of all the diets they tabulate. They emphasize the fact that the diabetic patient should be encouraged to keep thin rather than fat, and to do with as little food as will keep him in health. If, for example a patient is doing well on a mixed diet containing 50 grams of protein, 50 of carbohydrate, and 150 of fat, with a heat value of about 1,800 calories, he should be encouraged to be content, and not add to his dietary. They say that it is surprising to see how well most patients do on a diet with a heat value of only 1,500 or 2,000 calories. They note that a semi-starvation day of 150 grams of vegetables once a week, whether the urine contains sugar or no, is of value for the purpose of keeping well within the margin of safety, and of reminding the patient that he is on a strict diet. It is important, too, that the diabetic should take a considerable amount of exercise, as this enables him to utilize his carbohydrate diet better. Full details of the stages whereby the diet is increased are given by Dr. Hill and Miss Eckman, with directions for the cook and plenty of menus for the dietetician to choose from. It is clear that Dr. Allen's treatment has proved most successful in America, and it is much to be desired that it should be given a full trial in this country.

THE DIRECTION OF THE ARMY MEDICAL SERVICE.

THE Secretary of the War Office issued the following announcement on March 20th: "Surgeon-General W. Babbie, V.C., has been appointed to assist Surgeon-General Sir A. Keogh, Director-General Army Medical Services, especially in the work of supervision of invaliding and all questions connected with the physical fitness of the troops at home. The reports circulated in various newspapers to the effect that Surgeon-General Sir A. Keogh has resigned are quite untrue." On the outbreak of war Sir Alfred Keogh, who had been Director-General of the Army Medical Services from 1904 to 1910, was appointed Chief Commissioner of the British Red Cross Society in Belgium and France. Two months later it was decided to duplicate the office of Director-General of the Army Medical Services, and Sir Alfred Keogh was placed in charge of the office of Director-General at home, while Sir Arthur Sloggett became Director-General of the Expeditionary Force. This decision was taken on account of the amount of medical work connected with the Expeditionary Force on the one hand, and the home forces and new recruits on the other. It was a period of great anxiety for the medical services, especially with regard to sanitation and the prevention of epidemic disease, for the standing organizations had to be enormously enlarged, not only in France, but also, and perhaps even more urgently, in this country. Recruits were pouring in, and one of the consequences of our want of preparation for a European war was that no arrangements for their training or housing existed, so that almost everything had to be improvised. Mr. Tennant, in his speeches on the Army Estimates, has paid tributes to

¹ BRITISH MEDICAL JOURNAL, 1915, ii, 611.

² *The Starvation Treatment of Diabetes. With a Series of Graded Diets used at the Massachusetts General Hospital.* By L. W. Hill, M.D., and Miss S. Eckman, with an introduction by R. C. Cabot, D.M. Second edition. Boston: W. M. Leonard, 1916. (Pp. 132. 1.00 dol.)

the extraordinary success with which the difficulties were surmounted; and it will always be recognized that the great response which the medical profession at home made to the call for recruits, was due in large part to the confidence felt in the broad outlook which Sir Alfred Keogh took of the situation. Surgeon-General W. Babbie, V.C., graduated M.B.Glasg. in 1880, and entered the Army Medical Service in the following year. He received the C.M.G. for his services as senior medical officer in Crete in 1897-98, and the V.C. for his gallantry at Colenso. He was on the staff of the Natal Army, and was present at all the actions for the relief of Ladysmith, and subsequent operations in Natal and the eastern Transvaal, being promoted lieutenant-colonel and receiving the medal with five clasps. He was Assistant Director-General, 1901-1906, Inspector of Medical Services, 1907-10, and Deputy Director-General A.M.S., 1910-14. He was then appointed Director of Medical Services of the Army in India. Last year he became Principal Director of Medical Services, Mediterranean Expeditionary Force, Egypt and Malta.

THE CALCUTTA SCHOOL OF TROPICAL MEDICINE.

ANOTHER long step towards the realization of the scheme for establishing a great school of tropical medicine in Calcutta is recorded in our columns this week. Two years ago the Governor of Bengal laid the foundation stone of the laboratories; on February 26th last he laid the foundation stone of a hospital which will form an integral and essential part of the school, and those who attended the ceremony were able to inspect the laboratories. This is rather good going, though Sir Leonard Rogers seemed disposed to grumble because the pace had not been better. His original plan was for six professors in the tropical school, and it now seems probable that the ambition will be realized. Three professors were sanctioned by the Government, and afterwards a professor in pharmacology was sanctioned, as it was felt that the pharmacology of Indian drugs had been properly included in the scope originally assigned to the school; further, the imperial serologist, Colonel Sutherland, I.M.S., to whose pioneer work some reference was made in an article on blood stains published in the *JOURNAL* of February 19th, was given permission to lecture, and finally there appears to be good reason for hoping that the Rockefeller foundation will endow a separate professorship in protozoology, so that that subject may be separated from medical entomology. Commercial associations in India have undertaken to make annual contributions for five years, and endowments for three research workers have been provided, in addition to a special scholarship founded by Mrs. Mitra in memory of her husband, who was first medical officer and afterwards home minister for Cashmere. The Indian research fund, through the good offices of the Surgeon-General, Sir Pardey Lukis, has provided a lakh of rupees for the equipment of the laboratories, and the scheme has now been taken a step further towards completion by the realization of the plan for the erection of a special hospital, most of the money to defray the cost of which has been collected. The credit for all this is undoubtedly primarily due to Sir Leonard Rogers, Professor of Pathology in the Calcutta Medical College, who not only conceived the scheme but has known how to enlist the support of the Government and to appeal to the generosity of the public.

THE INFLUENCE OF SEX ON DISEASE AND MORTALITY.

The fact that sex *qua* sex creates a predisposition to certain diseases is of course a commonplace, but we do not perhaps recognize at how early an age this physiological influence of sex makes itself felt. As soon as the fetal heart can be heard it is found to beat more rapidly in the female than in the male, though the difference is

too small to enable the sex to be foretold, being in point of fact less than the difference observed between individuals of the same sex. At birth, boys on the average weigh four or five ounces more than girls. It has been suggested that the determination of sex may be dependent upon nutritional conditions affecting the mother, but in so far as this hypothesis assumes an abundant food supply to be favourable to the birth of males it is not supported by statistics. It is even asserted, though not, we believe, on any sound statistical evidence, that there is a marked excess of male births in poverty-stricken countries and those ravaged by war and famine. We referred in the *JOURNAL* of January 15th, p. 105, to some interesting investigations by Dr. R. J. Ewart bearing on the subject, and cannot pursue it further now. It seems clear, however, that the superiority in weight and size of male infants at birth is not due to better conditions of nutrition. At birth there are morphological differences, slight it is true, but still quite recognizable; for instance, the antero-posterior diameter of the abdomen is distinctly greater in male than in female infants, while the anterior superior iliac spines are more prominent, and the ischia more widely separated in girls than in boys, and so on. After birth these differences become more and more pronounced, so much so that even before puberty the boy and the girl have developed into two very distinct organisms, differing morphologically, functionally, and psychologically—differing, indeed, even pathologically. Those who advocate co-education do not seem to have considered this aspect of the question. A parallel education is conceivable, and even desirable, but the differences between the sexes is too great for any uniform system to be applicable. Boys and girls do not spontaneously play the same games. Girls are more precocious than boys, and their individuality asserts itself earlier. It is therefore not surprising that the two sexes should, from childhood onwards, display different pathological predispositions. The first indication of a distinct pathological predisposition is shown by the greater mortality among male infants, so much so that even though more males are born, by the end of the first year of life females may predominate. Tetany is said to be more frequent in boys and convulsions in girls, and the latter display an overwhelming liability to suffer from chorea. It may be argued that the larger size of male infants at birth renders them more liable to obstetrical traumatism, but this would only account for the excess of male mortality during the first few days of existence, whereas the excess persists throughout early childhood. The difference cannot be due to any lack of care affecting the male infant; on the contrary, in most countries the birth of a boy is the source of special congratulation. No influence can be invoked to explain this excess of male deaths except a less resistance to disease, a proclivity that operates in all latitudes. Taking the coefficient of mortality among female infants as 100, that of boys has varied from 123 in England and 121 in France to 110 in Serbia and Japan. This proportion holds good even in countries with a high all round infantile mortality, and the ratio is much the same during the age period 0-5 years. In the age period 5-15 the rates for the two sexes are almost identical, but after 20 years of age the mortality among females again falls in spite of the risks entailed by pelvic affections, pregnancy, and labour. Speaking generally, it may perhaps be said that the boy reacts more violently to disease than the girl, is more easily knocked over than the latter, does not recuperate as quickly when the illness takes a favourable turn, and does not offer as much resistance when suffering from chronic affections.

VENOUS THROMBOSIS IN MYOCARDIAL FAILURE.

In a monograph of the new series of the Johns Hopkins Hospital Reports, Drs. Sladen and Winternitz have collected from the literature of the last sixty years 48 cases of venous thrombosis occurring usually as a terminal

event in patients with heart failure. They add a case observed by themselves, and give an account of 15 more cases, 14 of them seen during recent years at the Baltimore hospital from which they write. The condition, they say, is one that has not met with the recognition its frequency and severity deserve. The patients were of all ages, and 46 of the total of 65 were females. The mortality of the thrombosis was 83 per cent., 36 of the patients dying within a month. Mitral stenosis had been thought the commonest cardiac lesion leading to the heart failure and thrombosis; but the authors found mitral stenosis either alone or in combination in 24 of the patients, mitral reflux in 35. The thrombosis occurs most often in the veins of the upper extremity, the left and right sides being about equally often affected. The iliac or femoral veins were involved in only 7 of the 65 patients. As for the signs and symptoms produced by the thrombosis, oedema was by far the commonest and not infrequently the only manifestation. Local pain and tenderness over the veins and palpable cords in the course of the vessels were the next most frequent indication; cyanosis and local coldness, evidences of a collateral circulation, loss of the jugular pulse, unilateral exophthalmos, and torticollis were among other signs noted. Three cases were not recognized clinically, general oedema being a marked feature in all three. Pulmonary embolism with the formation of an infarct was the most serious complication; no patient who recovered had shown signs of this.

THE PRICE OF DRUGS.

We publish elsewhere a letter from a correspondent on the subject of the high prices at present prevailing for many drugs; probably the increase of 50 per cent. in the cost of drugs for a year therein referred to is by no means an unusual experience. It will be remembered that at an earlier period of the war a circular was sent to the medical profession drawing attention to the shortage of existing supplies of many drugs, and recommending economy in their use; a failure of the usual sources of supply naturally means an enhanced price for such quantities as are available, while other causes—such as increased cost of transport and increased consumption—also play a part in raising prices. Several of the drugs showing the greatest increase in cost—such as salicylates, aspirin, bromides, phenacetin, potassium permanganate, atropine, and cocaine—were before the war either obtained entirely from Germany or were produced here from raw materials, such as bromine, coming principally from that country; others—like morphine and quinine—have always been made here, and their rise in price would appear to be due chiefly to the large demands of the army. Our correspondent suggests that the Association should endeavour directly, and indirectly through the Government, to induce manufacturing firms to produce drugs hitherto obtained from Germany. There is good reason for saying that the present high prices would seem to offer a sufficient inducement to manufacturers; if they have not taken up the production of the drugs in question on a large scale it must be because difficulties exist which are not easily disposed of. The increased demand for drugs due to the huge requirements of the army, and of chemicals of a great variety of kinds required directly or indirectly in modern warfare, has resulted in chemical and pharmaceutical manufacturers being extremely busy in executing orders, and this at a time when large numbers of their male employees have joined the army. These considerations have in many cases precluded the possibility of taking up new manufactures, which inevitably require a fair amount of experimental work; a further difficulty is that, owing to the vast amount of army work in the hands of engineering firms, it is a very difficult matter to get new plant constructed, while the congested state of railway transport makes its delivery when made a very slow matter. Nevertheless, in spite of all these and other

difficulties, manufacturers in this country are producing considerable quantities of some of the drugs formerly sent here by Germany, and there is good ground for believing that most of the manufactures so established will continue here after peace has been declared.

UNWARRANTABLE CRITICISMS.

MR. McNEILL's attack upon the arrangements for collecting and treating the wounded after some of the big actions in which the British army has been engaged in France seems to have aroused a good deal of indignation in the Expeditionary Force. Colonel Arthur Lee's statements in his speech reported at page 461, founded upon personal experience while occupying an official position which enabled him to watch the evacuation of the wounded, may be received with all the more confidence because of Mr. Chamberlain's frank admissions as to defective arrangements in Mesopotamia. In a private letter we have seen, from a writer in a good position to judge, the allegations of which Mr. McNeill made himself the mouthpiece are described as tragic nonsense. "I have been round the front recently," the writer says, "and do not know how any great changes for the better can be made. Mr. McNeill does not understand the situation, nor can he or anyone imagine it who has not been there. The base hospitals," the writer continues, "within a fortnight after Loos were practically normal again, except for the retention of some of the worst cases which it was thought inadvisable to move. This is a great tribute to the administration, and there was little or no delay anywhere." One base alone got "8,000 cases within a very few days, and among them there were in that fortnight only 60 deaths"; although a large proportion of the casualties notified were, of course, only slight wounds, they filled up the hospitals temporarily. "There are," the letter continues, "grouzers who complain that they have no work suitable to their high qualifications, but these are just the people who do not do the work waiting for them. Thank God the majority of the profession is playing the game!... Take Mr. McNeill's remarks about stretchers. Field ambulances were grabbing stretchers indiscriminately; orders were given to disgorge to a proper distributing centre, and at the same time to obtain an extra supply. If more were wanted, a chit for the supply of fifty stretchers, for example, would bring them back with the car or cars which went to fetch them. So, you see, there is truth in what Mr. McNeill says! There was, however, no complaint of want of stretchers."

THE Royal Medical Benevolent Fund Guild, which works in co-operation with the Royal Medical Benevolent Fund to assist, by personal service, the families of medical men who, owing to the death or incapacity of the breadwinner, are reduced to poverty, is always glad to receive gifts of clothes, including secondhand boots and shoes in good condition, and household linen. As was shown by the report of the annual meeting of the Fund, published in the JOURNAL of February 26th, the Guild is now called upon as a result of the war to deal with many widows and children who in happier times would not have dreamt of asking for assistance. We are informed that the cupboards at the clothing dépôt, 43, Bolsover Street, W., are very bare, and that clothes suitable for boys and girls working in offices, for women and for old men, are much wanted. They should be sent to the secretary of the Guild at the address mentioned.

It has been suggested that benevolent societies be formed for the benefit of the families of officers and other ranks of the medical services auxiliary to the Regular Royal Army Medical Corps—namely, the Special Reserve, the Territorial Force, and new army. Funds

would be raised by voluntary subscriptions, and it has been proposed that each branch of the service should appoint a committee of five to seven members to administer its own funds. A meeting, presided over by the Director-General, will be held in the Lecture Theatre of the Royal Army Medical College, Grosvenor Road, S.W., on Wednesday, May 10th, at 3 p.m., and it is hoped that as many officers as possible will attend. In the meantime any inquiries may be referred to Lieutenant-Colonel G. St. C. Thom, R.A.M.C., War Office, S.W.

It is satisfactory to note that among the Shakespeare tercentenary celebrations tributes of honour from the medical profession to the memory of our greatest poet will not be wanting. Sir St. Clair Thomson has chosen "Shakespeare and Medicine" as the subject of his oration to the Medical Society of London on May 1st. This date has been fixed for the oration so that it may take its place in the programme of official celebrations. Another homage from the profession will be paid by Mr. Alban Doran, who has written the article on Shakespeare's medicine in *Shakespeare's England*, a volume designed on lines laid down by Sir Walter Raleigh and Sir Sidney Lee which is to be issued from the Clarendon Press.

Medical Notes in Parliament.

A Year of War.

(Continued from p. 430.)

ARMY MEDICAL ORGANIZATION.

ARMY MEDICAL SERVICES IN FRANCE.

Colonel Arthur Lee's Reply to Mr. McNeill.

IN the course of the debate on March 16th Colonel Arthur Lee (formerly R.A., and British Military Attaché with the United States army during the Spanish-American war, and now parliamentary secretary to the Ministry of Munitions) began his reply to Mr. McNeill, complaining that he had disfigured his speech by very bitter personal attacks upon distinguished officers of the Army Medical Service who were not in a position to defend themselves in public. His reason for speaking was not, Colonel Lee said, his present office, but the fact that for nine months he had been Lord Kitchener's special personal representative to report to him upon the practical working of the medical services in the field, especially with regard to the collection, care, and evacuation of the wounded at the front. He had, he admitted, no special qualification for the work, except the fact that as a soldier he had some knowledge of the practical difficulties which distinguished war conditions from those of peace. The distinction was often forgotten by critics, who, animated no doubt by the most disinterested motives, were apt—he was referring to professional critics, whether they came from Glasgow or Portland Place—not to realize the difficulties with which the medical services were confronted, and had been led in many instances to be grossly unfair to their colleagues overseas. He had had unique opportunities of watching the daily and nightly work of the medical services at the battle of the Aisne, at both battles of Ypres, at Neuve Chapelle, at Festubert, and at other places that had been mentioned. In the harrowing tale Mr. McNeill had told he failed to recognize anything which in the faintest degree corresponded to the facts as he saw them. Mr. McNeill had already shown himself over-credulous in regard to other matters—witness his discovery of two million impending war babies, reduced after investigation to two false alarms and one case of twins. He had again shown this defect in this instance. If there was, Colonel Lee continued, any official at the War Office universally recognized as a success in view of his great talents, his alert and far-seeing mind, his wisdom, patience, and urbanity in dealing with innumerable complaints and representations, it was Sir Alfred Keogh. He was entitled to the highest praise, and it was true that there had been no specially bitter attack upon him. There had, however, been a very bitter and vicious attack upon Sir Arthur Sloggett and Surgeon-

General Macpherson. Mr. McNeill had complained that Sir Arthur Sloggett did not combine the organizing skill of Napoleon with the scientific genius of Lister and Paget. These were rare qualifications, and when a man possessing them was found Colonel Lee would, he said, be the first to support his being placed at the head of the medical services. Whether the distinguished informants who supplied Mr. McNeill with the material for his attack believed that they possessed these high qualifications or not he did not know, but he had met in this country surgeons who had not made the sacrifices these officers had made, who had given him the impression that they probably held a higher view of their qualifications than was generally held by their profession at large. Sir Arthur Sloggett had great qualities for the position of head of the medical services in the field—great experience, extraordinary tact, and great powers of dealing with the difficult personal situations bound to arise, such as that which arose at the beginning of the campaign between the Royal Army Medical Corps and the Red Cross. He was very accessible to suggestions, and was responsible for establishing in the field that Advisory Council of eminent civilian surgeons who met periodically and gave the medical services the benefit of their advice.

Festubert, Ypres.

With regard to the attack on Surgeon-General Macpherson, on the ground that there had been a terrible breakdown in the medical arrangements at the battle of Festubert, Colonel Lee said that he had been specially commissioned to watch the medical arrangements throughout that battle, and there was no breakdown. The evacuation of the wounded proceeded without a hitch, in spite of the fact that an enormous number of wounded had to go through one clearing station. There was no criticism at the time, no complaint by officers or by men, and he thought that Mr. McNeill had been very misinformed. It was not true that Surgeon-General Macpherson had been removed from the first army to another on account of the breakdown, nor that he had subsequently been removed to Salonika. Surgeon-General Macpherson was selected to go to Salonika on account of his high qualifications.

With regard to the general criticisms of the organization of the medical services, Colonel Lee said that he thought it would be a fatal mistake to deprive the divisional medical arrangements of their mobility. One of the chief anxieties of the heads of the medical service had been lest the sedentary character of the war at the moment should deprive the medical service of its flexibility, power of rapid movement, and of adapting itself to new conditions, all of which were necessities in the event of the army advancing. As to Mr. McNeill's statements about the first and second battles of Ypres, Colonel Lee said that they bore no relation whatever to the facts. It was not a mistake to establish a clearing station at Poperinghe; it was the only town within easy reach of Ypres where there was any building of sufficient size. It was not under fire, and was suitable in every way except that there was only the one broad, good, smooth road. If Mr. McNeill had known anything about the conditions of war he would not have suggested that the wounded should be diverted to the other clearing stations at Haasbruck and Bailleul. Had he known the state of the side roads in Flanders he would never have suggested that the wounded should be subjected to the atrocious agony of being carried over them, even in the best motor ambulances. As a matter of fact the wounded were not evacuated from Ypres by motor ambulances but by trains. He could speak confidently on the subject, for he had seen practically every wounded man evacuated and taken out of the area. On October 31st, 1914, 1,600 wounded men were evacuated in the course of the night without any hitch of any sort, an achievement which reflected the greatest credit upon the Army Medical Service. As to Hooge, where it was said that doctors worked forty or fifty hours at a stretch, whilst medical staffs of other divisions were waiting at Ypres with nothing to do because their troops were not engaged, the suggestion was perfectly ludicrous to any one who knew how hard pressed we were. There was not one single unit not engaged in the battle, and every man—cooks, typewriters, and non-combatants—was put into the firing line. As to the eighty men Mr. McNeill alleged had been forgotten, a good deal could be

said, but it was sufficient to say that they were not British. As to the charges that men were left lying out, Colonel Lee said that the collection of the wounded and their evacuation had been carried out with dispatch and regularity never before known in war. He challenged Mr. McNeill to produce evidence to satisfy any reasonable man that there had been anything approaching a breakdown in any of these great battles. Colonel Lee added that in the course of his duties he had interrogated thousands of officers and men at every stage from the front to the base hospitals, but so far from hearing complaints, he heard one long story of gratitude and praise of the way in which they had been treated by the medical services. Two services had in general been outside the fire of criticism—the commissariat and the Army Medical Service.

"Movable Hospitals": Clearing Stations.

As to the argument that the fact that the men arrived home with septic wounds was proof of neglect, the truth was that every wound was septic from the moment it was inflicted. Colonel Lee expressed his inability to understand what Mr. McNeill meant by field hospitals at the front. [Mr. McNeill interposed to say that he had only repeated what he had been told.] As to Mr. McNeill's suggestion that the wounded should be attended by a system of movable hospitals with easy access by motor car, Colonel Lee said that if by hospitals were meant buildings or marquees, with operating rooms, surgeons, nurses, anaesthetics, and everything necessary for operating under modern conditions, then they existed already as close to the firing line as was compatible with not being under shell fire. That was an important point; it was not a question of whether a surgeon and his assistants were afraid, or not afraid, but whether it was physically and mentally possible to conduct operations in a hospital into which a high-explosive shell was liable to be dropped. The experiment had been made, and in some instances hospitals had been pushed up towards the zone of shell fire, with deplorable results to the patients and staff. If the suggestion meant some new form of movable hospital pushed up in close proximity to the firing line, then in the first place the military authorities would not allow it, because it would hamper them; and in the second, it would instantly be spotted by enemy aeroplanes and become the constant mark of artillery fire. Again, what was to be done with the wounded man after he was operated upon in a movable hospital? A movable hospital was meant to move, but after an abdominal operation a man must be kept quiet for a week. The only possible advantage would be that a man could be operated on a few minutes—at the outside half an hour—sooner than he would have been at a clearing station.

Abdominal Operations and Compound Fractures.

It was not the case that opportunities for doing abdominal surgery had never been instituted; they had existed during the whole time he (Colonel Lee) was at the front, and in standing orders issued to the medical service on March 27th, 1915, there was reference to the conditions under which abdominal operations should be conducted, not merely in the clearing stations, but, if necessary, in the field ambulances. The abdominal operations had been singularly successful and there had been a very large proportion of recoveries. The same statement applied to compound fractures. Mr. McNeill had really once more succeeded in discovering what Lord Morley, when he was a member of the House of Commons, used to describe as a *nidus equinus*.

Dentistry.

It was not true that dentistry was neglected; at every station along the whole front there was a well qualified dental surgeon, well equipped with appliances.

Nidus Equinus.

Mr. McNeill had called for an investigation—a few competent and disinterested, not necessarily technical, investigators to be sent out to corroborate the horrors he had described. He wanted the tree pulled up by the roots to see how it was growing. Colonel Lee concluded by saying that he was under no obligation to the War Office, and that to serve Lord Kitchener for nine months sometimes brought more kicks than ha'pence. He had felt impelled by a sense of common justice and decency

to make a vigorous protest against Mr. McNeill's unjustifiable, violent, ill-informed and baseless attack upon a body of as highly skilled, devoted, and gallant men as ever served the State. They deserved not censure, not carping criticism, not personal libels, but the whole-hearted gratitude of the whole community.

Sir John Spear said that it was comforting to hear of the great devotion of the medical men, and the great care taken of wounded soldiers, but Mr. Hodge complained that the accusation that a large numbers of stretchers gathered together before the battle of Loos had been dispersed because the number was in excess of regulations had not been answered. Mr. Hodge also complained that the War Office was doing nothing for nurses who had been broken in the war. They got twenty-six weeks' sickness benefit from an approved society, and after that an invalidity pension of 5s. a week, but nothing from the War Office.

MR. TENNANT'S REPLY.

Mr. Tennant, in a general reply, touched first upon this point. The devotion and self-sacrificing services rendered by the nurses throughout the war were appreciated, and he would take care to see that proper action was taken, but he suspected that Mr. Hodge was referring to members of Voluntary Aid Detachments and not to nurses permanently attached to the army. With regard to the Army Medical Advisory Board, Mr. Tennant said that Sir Alfred Keogh's attention at the outbreak of war was particularly directed to sanitation, which was more important than anything else, for everyone knew that the expectation was that more would die of disease than of wounds. That had been so in nearly every great war, and this war was very unusual in that respect. The responsibility for the sanitation in France had been placed upon an advisory board, to which Dr. Hill was added as a physiologist to deal with poisonous gases. The work done by this body against the gas attacks had been quite extraordinary. He believed that Mr. McNeill now admitted that the work done by the army medical authorities had been admirable, but, Mr. Tennant continued, he regretted very much and would resent on behalf of his medical advisers any false impression such as the speech of Mr. McNeill would have created had it not been for the speech of Colonel Lee. Mr. McNeill interposed to say that he had not spoken from his own knowledge, and had said nothing which he had not been told by people who had seen as much as Colonel Lee, and were in many respects more qualified to judge. Mr. Tennant said that that was a matter of opinion, but he was amazed to hear such a statement, because every soldier he had met from the front, and all persons who came from the front, said that the medical services had really left nothing to be desired. It had been wonderful, and Sir J. Walton exclaimed: "The best there ever was in the world."

MESOPOTAMIA.

On March 22nd Colonel Yate called attention to the operations in Mesopotamia, and criticized the arrangements. The Secretary of State for India, in his reply, said that the campaign began as a comparatively small operation within the resources of the Indian Government. It had grown until it had exceeded those resources, and he was heartily glad that the ultimate control was now exercised by the Imperial general staff at home, acting through the Government of India, the military authorities there, and the general officer commanding on the spot. That transfer had already proved itself advantageous. Mr. Chamberlain went on to say that he had to admit that there had been a lamentable breakdown of the hospital arrangements. He did not seek to palliate some of the things which he had learnt had taken place, but it should be remembered that the campaign had been carried on in circumstances of very great difficulty. According to his latest information—though he was not in a position absolutely to vouch for its accuracy—there had been an abundance of hospital supplies of all kinds at Basra at all times. He thought that there had been a great, and he was inclined to believe inexcusable, shortage of necessary medical appliances above Basra. That was due in large part to the enormous difficulty of river traffic. There had been a shortage of transport; only particular types of river craft, with a very shallow draft, were suitable for the purpose. Recourse was had to Egypt and other countries, but there had been misfortunes in regard

to some of the transports, which had been destroyed or lost by perils of the sea en route. But though the shortage of river transport accounted for a good deal, it did not account for all, and neither the Government at home nor the Government of India were satisfied with the state of things which had prevailed. As Mr. Long had stated, General Bingley and Sir William Vincent had been instructed to proceed to Mesopotamia and investigate the medical arrangements there. The inquiry would not interfere with the urgent work now to be done, but it was necessary that the Government should be informed as to the facts and in a position to weigh and apportion responsibility. The commissioners had begun their inquiry in Bombay, where they had seen officers invalided from the front, and they had sent home questions they desired to be addressed to certain officers invalided home. They had now gone on to Mesopotamia, and he hoped that the steps taken had already worked an improvement, and would prevent a repetition of those occurrences of which complaint had been made. General Aylmer had reported that he was extremely satisfied with the arrangements made for the wounded in the field after the recent action. A large number had already been sent down stream, and the rest were following. Mr. Hobhouse expressed the hope that the responsibility would be brought home to those who had allowed men to perish, while serving the country, for want of care and foresight. Mr. Chamberlain intervened to say that while it was his feeling and belief that there had been inexcusable deficiencies in the arrangements for the treatment of the wounded, he hoped the House would keep an open mind until the information was completed. He was profoundly dissatisfied with the information which had reached him, but he did not know the truth, could not depend upon private letters, and did not wish to be held to have uttered any judgement on anybody. Mr. Hobhouse agreed that to judge now a case of this gravity would be unfair both to those who were making the inquiry and to those who were the subject of it.

Unfit Men.—In the discussion of the Army Estimates Major Astor gave several instances of the enlistment of medically unfit men. Such men were useless in the army, were unfit for the mildest form of home defence, were costing the country much money in allowances, and were prevented from doing useful work as civilians. The War Office should get rid of these men at once, so that they might find occupation. He said also that many men were spending months in hospitals undergoing treatment before they were discharged, but nothing was being done to assist them in the way of getting employment and acquiring skill which would be of use to them after their discharge. The true policy was to let every man realize that when he left the army he could serve the State by increasing the production of the country. Mr. Anderson alleged that some doctors were making the test too low, and accepting men who were of no value from a military point of view. Mr. Long, in his reply, admitted that there was an accumulation of men at home who were unfit for foreign service. He said that the Committee over which he presided had the matter under investigation, and that it was also engaging the attention of the Field Marshal Commanding-in-Chief the Home Forces and the Adjutant-General. Returns had been prepared showing that the men unfit were at once put under orders for discharge so that they might be useful in industries. On March 21st Mr. Tennant said, in reply to a question, that a man voluntarily attested, who, on being called up in his group, was not found fit for any service by the medical board was not accepted.

Spectacled Soldiers.—In an answer to Sir Henry Craik, on March 16th, Mr. Tennant stated it was not the case that men were rejected on account of defective distant vision which could be corrected by glasses. It was true that a considerable number of men who had glasses were now serving in the army. The British standard of vision for general service was not regarded as abnormally high. It was fixed by a joint committee of military officers and ophthalmic experts.

Venereal Diseases.—In reply to Colonel Lockwood, on March 21st, Mr. Tennant said that in Egypt during the last eight weeks the percentage of admissions for venereal diseases had averaged 0.09 per cent. per week, which he understood was equal to an average annual admission ratio of 46.8 per 1,000. No figures had been received for Salonika.

Cerebro-spinal Meningitis.—In reply to Mr. Chancellor, on March 16th, Mr. Tennant said that fifteen soldiers were now segregated at the Fulham Military Hospital as carriers of cerebro-spinal fever infection. Two soldiers segregated as carriers had developed the disease in acute form. The Army

Council were advised that these carriers should be segregated, not because they had actually communicated the disease to other persons, but in order to prevent them from doing so.

Pensions.—Mr. Tennant has informed Mr. Watt that pensions are granted to the widows of soldiers killed by accident while in the performance of military duty. In reply to Mr. Watt, the Financial Secretary to the War Office said that in the case of soldiers who, having done long spells of service in the trenches, lost their mental balance or were suffering from severe mental strain, while there was ground for hope that a permanent cure would be effected in a reasonable time, the men were not discharged, but given light duty at home. When discharge was necessary from the causes mentioned a pension was awarded.

Tuberculosis.—In reply to Major Astor, on March 16th, Mr. Tennant said that the only men discharged from the army not eligible for sanatorium benefit under the National Insurance Act were those who refused to become insured on entering the army. The number was unknown.

Nervous Shock.—In reply to Sir John Jardine, on March 21st, the Financial Secretary to the War Office said that the War Office was directly and wholly responsible for the care and treatment of uncertifiable soldiers invalided through nerve shock. Any payments made to the asylum authorities or Board of Control in this connexion were made to them as agents of the local military authorities. Mr. Tennant stated that cases requiring special but not prolonged treatment were transferred to one of the Territorial Force general hospitals or to other appropriate hospitals. Severe cases requiring prolonged treatment were transferred to the British Red Cross Hospital at Maghull or the Springfield War Hospital at Wandsworth.

Pay of Medical Officers at Asylums.—In reply to Mr. King, on March 15th, the Home Secretary said that medical officers of asylums adapted as war hospitals, who had been granted temporary commissions in the Royal Army Medical Corps, received in most cases the pay of their rank and not their asylum salary. In those instances in which the pay of their rank was less than their asylum salary, they were paid at the higher rate, and this would continue as long as the institution remained a war hospital. In one or two cases, where the circumstances were exceptional, special arrangements had been made.

Dope Poisoning.—In reply to Mr. Rowlands, on March 21st, Mr. Brace said that the obstacle to the use of the non-poisonous dope in aircraft factories was that one of the essential ingredients was not produced commercially in this country at present. The departments concerned were making every effort to arrange for an increased supply, and new instructions embodying further administrative measures for guarding against the danger had been issued by the Home Office to all aircraft factories. Steps were being taken to extend the use by contractors of a dope made under War Office supervision, which contains as little tetrachlorethane as possible.

THE National Council for Combating Venereal Diseases proposes to organize a number of conferences and courses of lectures, and to issue a summary of the principal conclusions of the Report of the Royal Commission. An appeal for financial support has been issued, and is signed, among others, by the President of the Council, Lord Sydenham, who was Chairman of the Royal Commission; Sir Thomas Barlow, Chairman of the Executive Committee; the Presidents of the Royal College of Physicians, the Royal College of Surgeons, and the Central Midwives Board, Sir Rickman Godlee, Sir Malcolm Morris, Dr. F. W. Mott, and Mrs. Scharlieb, M.D.

AT the monthly meeting of the Committee of the Medical Sickness and Accident Society on March 17th the accounts presented showed a margin in favour of the society in the sickness expectation—a rather unusual event at this time of the year. With so many members serving in all parts of the world with the R.A.M.C., it is impossible to regard the experience as normal, and all calculations are set out of gear and upset. The new business was better than for the preceding month, and the amount of sickness benefit insured by each member has risen. The fees of locumtenents are higher, and this is reflected in the sum necessary to cover this expenditure. The Combined Sickness Benefit and Endowment Assurance Scheme, although limited in its amount, appears to be popular owing to the rate at which it is offered to the profession, and the committee feels that its decision to reopen the life assurance branch on sound lines has been justified. The contract for sickness benefit holds good until age 65, and at that age the annuity scheme, which will be submitted for approval at the annual meeting, will, it is believed, prove a useful and valuable benefit in place of the sickness benefit. For full prospectus apply to the Secretary, Medical Sickness and Accident Society, 300, High Holborn, W.C.

THE WAR.

CHEMICAL WORK.

(From a Correspondent in Northern France.)

In many of the arrangements of the Army Medical Service in France there is an air of permanency a little depressing from one point of view, but highly satisfactory from another. On the one hand it suggests that the authorities foresee a much longer stay in France than any one can care to believe possible; on the other hand, it induces a conviction that so far as the environment can contribute to the success of medical work, whether prophylactic or curative, nothing feasible is or will be left undone.

At least half a dozen mental images occur in this connexion, but the particular institution which happens to have evoked the thought is one of the hygiene laboratories. There are several of these doing chemical work with the field armies in the guise of mobile laboratories, but that now in mind is a stationary laboratory which forms part of the outfit of the sanitary officer of the principal hospital and evacuation base.

The rooms occupied are part of a building used in peace times as a dried fish warehouse, but they have been so completely transformed as to make it difficult to realize the fact. The main room, besides being well lighted, is very large, and the whole place is thoroughly well equipped. It is possible, therefore, to undertake all the work that commonly falls to the lot of the chemical department of a well-organized public health laboratory at home, and also a certain amount of research work should opportunity for its performance occur.

The routine work of the laboratory consists in helping to safeguard the health of the troops by examining water supplies and testing for impurities the thousand and one forms of preserved and other foods issued by the Army Service Corps for use in the camps and hospitals.

Thus it comes about that there is generally to be seen on the shelves an array of samples awaiting their turn for examination, and seemingly always the same, but in reality daily changing. To specify them would take too long; it must suffice to say that they range from tinned mushrooms to bully beef, and from paraffin oil to powders sovereign against lice.

The routine work done at the mobile hygiene laboratories is of the same general order, but a good deal of their time is often taken up by a form of sanitary police work—namely, keeping an eye on the way in which the men told off to chlorinate water carry out their instructions. The supervision is exercised not by actually watching the men at work but by taking specimens of water served out as ready for use and testing it in various ways to see whether the work has been intelligently as well as conscientiously performed. At none of the laboratories does the officer in charge work single-handed. Sometimes there are two, sometimes three, collaborators.

In common with the workers in bacteriological laboratories, most O.C.'s of hygiene laboratories try to keep going some side line in the nature of original research. Any expert chemist at work in France and versed in the physiological as well as other aspects of his profession is bound to perceive problems whose solution would be of direct benefit to the army, and opportunities for tackling these are gladly seized if the amount of routine work on hand leaves any time available.

As instances may be quoted an endeavour made at the laboratory more specifically mentioned in this note to establish a means of identifying genuine cases of shock—not the shock consequent on exposure, severe injury, or the performance of a prolonged operation, but the peculiar condition to which Laurent, in the first Balkan war, applied the old term "*commotio cerebri*," and known out here as "shell shock."

In many instances of supposed shell shock the diagnosis may, no doubt, seem luminously clear, but in others there is plenty of room for difference of opinion. Moreover, whatever may be the view taken of the difficulties these cases present, it could not fail to be advantageous to have at command some datum which being both material and positive would be as independent both of patient and observer as a thermometer reading.

The central conception is to use the sugar contents of the blood in the confirmatory diagnosis of these cases, the reasoning in general outline being much as follows: It is well recognized that one of the sequences of any grave disturbance of the central nervous system may be loss of control by the latter over the formation or retention of sugar, and when evidence of such loss is sought it is to the urine that the clinician turns. But sugar in very minute quantities is a normal constituent of urine, and all the tests for its presence in abnormal amount are of a very coarse kind. Consequently no one who uses urine analysis as a means of throwing light on the condition of the central nervous system can feel that he has obtained any assured guidance from his work. Loss of sugar control may exist, but the tests used may have failed to reveal it.

But this does not mean that sugar observations are necessarily useless. Any sugar found in urine must be derived from the blood, and if the sugar contents of the latter could be shown to be altered, such alteration would be better evidence of loss of control than could be any testimony derived from the urine. This would be true even if the tests applied were in both cases equally delicate and precise, for the examination is made at a stage nearer the *causa causans*—that is, the condition of the nervous system—and the evidence obtained would therefore be more direct.

Consequently the aim of the research has been to determine whether there is any method of sugar separation and titration so delicate as to be capable of determining with precision the variation of the sugar contents of the blood above or below the nominal physiological limits, and yet sufficiently simple to be used with the rapidity and frequency required when the final aim of the process is clinical.

The answer so far obtained seems to be in the affirmative, the process employed being a modification of the method of Bang. The distinctive feature of this method is the titration of very minute quantities of cuprous oxide by means of iodine. In the modification the much more delicate reaction of titanium trichloride with ferric chloride and thiocyanide is employed. In both processes the amount of blood required is as little as two drops. Full details of the modification will, it is understood, be made generally available by the publication of a paper thereon at an early date.

A second investigation now in progress at the same laboratory relates to the extreme breathlessness noted in early cases of trench nephritis. It is not known whether this is due to acidosis or some other cause. In the attempts to determine this point made in England the tests have been applied at a date too late for the results to be in any wise conclusive.

GERMAN EXPERIENCES.

NEURASTHENIA AMONG SOLDIERS.

At a meeting of the Berliner medizinische Gesellschaft last November Dr. Stadelmann, attached to a reserve military hospital, said that 50 per cent. of the invalid soldiers under his care suffered from neurasthenia, and this accounted for as many medical casualties as all the other complaints—such as rheumatism, pulmonary catarrh, etc.—put together; 50 to 70 per cent. of these neurasthenic patients complained of symptoms referred to the heart, but only about 5 per cent. suffered from real heart disease. Most of these patients, particularly the middle-aged, did not wish to recover, dreading a return to the front. Radical measures were necessary in order that the army should not be deprived of the services of this large body of men; they should not be sent home, but should be kept in convalescent quarters behind the front. This plan was already adopted on the western front. Dr. Albu gave an account of his many failures earlier in the war in such cases. At first he kept his patients in bed, often for many weeks; he seldom found them any the better, and even when tachycardia was diminished by rest in bed it usually returned as soon as the patients began to move about again. He had given up this treatment and drug treatment also, having found that even bromine preparations were quite useless. Far better results were obtained when the patients were made to walk and were given light work, and when everything was done to distract their attention from their symptoms. A third speaker, Dr. von

Hansemann, whose experience was gained in a convalescent institution, also emphasized the importance of treating these cases as psychic rather than as organic. He gave his patients plenty of freedom to walk about, so that they might learn to rely on themselves again. The influence of parents, wife, and children was, he said, most detrimental.

TREATMENT OF TYPHOID FEVER AND DYSENTERY.

Dr. F. Meyer praised digitalis in the treatment of typhoid fever. In every case, whether there was an immediate need for cardiac stimulants or not, digitalis was given as a routine measure, and since this treatment had been adopted systematically there had been a great reduction in the frequency of cardiac complications. The administration of killed and sensitized bacilli had never in his experience provoked a further rise of temperature; in many cases the fever fell rapidly. Inoculation late in the course of the disease averted relapses. In very severe cases he had given injections of 20 to 30 c.cm. of blood taken from persons whose fever had ceased and whose acquired immunity to typhoid was raised. He had never seen ill effects from this treatment, which often brought the fever down rapidly. In dysentery he had learnt to rely principally on castor oil and polyvalent serum. Liberal doses of castor oil were most efficacious. He had never seen any disaster follow the administration of serum, but he had sometimes found it inert. This was because he did not at first always use a polyvalent serum, and as his material included cases infected with the Shiga-Kruse bacillus, as well as with the Y bacillus, it was clear that only a polyvalent serum would meet the needs of every case. Among his severe cases the mortality was only 3 per cent., and among severe and light cases together it was only 1.2 per cent.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON-PROBATIONER JAMES JOHNSTON, R.N.V.R., was reported as killed in a list of naval casualties published on March 13th. He ranked from July 28th, 1915. His death took place on February 29th, at the age of 20; it is not stated where. He was the fourth son of the late Thomas Johnston, farmer, of Witheote, Oakham.

ARMY.

Killed in Action.

Third-class Assistant Surgeon Alexis Renwick Emmett, of the Indian Subordinate Medical Department, was reported, in the casualty list published on March 17th, as killed in action in East Africa. He was born on November 13th, 1884, entered the Bengal army, and attained warrant rank on February 27th, 1905, being promoted to the third class on February 27th, 1910. He had previously served in the north-west frontier of India, in 1908, in the operations in the Zakka Khel country and in the Mohmand country, receiving the frontier medal with a clasp. Before the war he was in civil employ in the Central Provinces. He was attached to the second battalion of the Loyal North Lancashire Regiment.

Lieutenant John Wilson, R.A.M.C., was notified as killed in France in the casualty list published on March 18th. He was the son of the late Adam Wilson, of Armadale, was educated at Edinburgh University, where he took the M.B. and Ch.B. in 1909, and was in practice at Hamilton till he took a temporary commission in May, 1915. He was attached to the 10th battalion of the Duke of Wellington's Regiment, the old 33rd Foot.

Accidentally Killed on Service.

Lieutenant Gavin Neil Murphy was killed by a fall from his horse in France, on March 12th, aged 42. He was the youngest son of the late Hugh Gavin, of Stirling, was educated at Stirling High School and in the school of the Royal College of Surgeons, Edinburgh, and took the Scottish triple qualification in 1901, also the F.R.C.S. Edin. in 1903. He then joined the Irish Presbyterian mission hospital at Anand, in the Bombay Presidency, and had only recently taken a temporary commission in the R.A.M.C. He married Miss Maud Muriel Stevenson, M.B. Edin., daughter of the late Dr. Fleming Stevenson

of Dublin, who was serving as a lady doctor in the same mission hospital, and leaves a widow and four children.

Died on Service.

Captain William Gem, South African Medical Corps, was reported, in the casualty list published on March 14th, as having died while serving with the South African Expeditionary Force. Neither date nor place were stated. There are expeditionary forces from South Africa now serving in Egypt and in East Africa certainly, perhaps also in France. He was educated in Dublin and took the diplomas of L.R.C.P.I. and L.R.C.S.I. in 1881. Before the war he was medical officer of health of Krugersdorp, in the Transvaal. He was medical officer of the 10th South African Infantry (Witwatersrand Rifles).

Captain Percy Brewster Ridge, R.A.M.C. (T.F.), of the 4th London General Hospital, died at Denmark Hill, London, of pneumonia, on March 12th, aged 33. He was educated at Queen's College, Cork, where he was senior exhibitor, and graduated as B.A.O., M.B., and B.Ch. of the Royal University, Ireland, in 1906. After serving as senior house-surgeon of the Prince of Wales General Hospital and Cancer Hospital, and as pathologist to the Royal Hospital for Diseases of the Chest and to the City of London Hospital for Diseases of the Chest, he became assistant pathologist and curator of the museum of King's College Hospital and lecturer on morbid anatomy to the hospital medical school. He had only recently joined the 4th London General Hospital as a captain.

Lieutenant Percy Haycraft Berry, R.A.M.C., was reported, in the casualty list published on March 17th, as having died in Egypt. He was educated at Cambridge and at Guy's Hospital, took the M.R.C.S. and L.R.C.P. Lond. in 1913, was in practice at Watford, and joined the army as a temporary lieutenant in May, 1915.

Captain Arthur Ryland Chavasse, R.A.M.C., died of pneumonia at No. 2 General Hospital, British Expeditionary Force, in France, on March 12th, aged 28. He was the only son of the late Sir Thomas Chavasse, of the Linthurst Hill, Barnt Green, Worcestershire; was educated at Oxford, Dublin, and St. Thomas's Hospital, and graduated as B.A. Oxon. with honours in physiology in 1908, and as M.A., M.B., and B.Ch. in 1911, also taking the M.R.C.S. and L.R.C.P. Lond. in the same year. He had acted as clinical assistant in the children's medical department, as house-physician, as casualty officer, and as senior obstetric house-physician at St. Thomas's, and as resident medical officer of Queen Charlotte's Hospital. He took a temporary commission as lieutenant in the R.A.M.C. on February 15th, 1915, and was promoted to captain on completion of a year's service.

Wounded.

Captain J. E. M. Boyd, R.A.M.C., Mesopotamia.
 Captain J. H. Fletcher, R.A.M.C. (temporary), France.
 Captain H. P. Hart, R.A.M.C., Mesopotamia.
 Captain H. K. Rowntree, I.M.S., Mesopotamia.

Missing, believed a Prisoner of War.

Captain R. T. Vivian, R.A.M.C., Mesopotamia.

DEATHS AMONG SONS OF MEDICAL MEN.

Cemery, Percival Conrad, Acting Quartermaster-Sergeant, 14th Battalion, Hants Regiment, fourth son of Lieutenant J. B. Cemery, R.A.M.C., of Aston Villa, Brockenhurst, and late of Alton, killed in Mesopotamia on January 21st, aged 26.

Edwards, Harrington Douty, Lieutenant-Commander R.N., son of Lieutenant C. R. Edwards, R.A.M.C., lost at sea about March 11th. He entered the navy as a cadet in 1902, and became lieutenant-commander in October, 1914. He was decorated with the D.S.O. in August, 1915.

Farrar, Valentine Anstruther, Second Lieutenant 17th Battalion Lancashire Fusiliers, second son of Dr. Reginald Farrar, of the Local Government Board, now a major in the R.A.M.C., died on March 17th, in France, of wounds of the head received on March 15th. He was educated at Harrow and at Magdalen College, Oxford, where he was an exhibitor. At the beginning of the war he enlisted in the Public Schools Battalion of the Royal Fusiliers, got a commission on September 9th, 1915, and left for France in January, 1916. He was a grandson of Dean Farrar.

Giffard, Colin Hay, Captain 1st Battalion, King George's Own First Gurkha Rifles, son of Douglas Giffard, M.R.C.S., of Merlindale, St. Winifred's Road, Bournemouth, killed in Mesopotamia on March 8th, aged 32. He was born on December 11th, 1883, served in the embodied militia from October 6th, 1900, to July 16th, 1901, and entered the army as a second lieutenant in the South Wales Borderers on December 4th, 1901. He joined

the Indian Army as lieutenant on June 20th, 1903, was posted to the 1st Gurkhas on March 6th, 1904, and became captain on December 4th, 1910.

Hackman, Cedric Craven, 13th Battalion (Kensingtons) County of London Regiment, killed somewhere in France on or since May 9th, 1915, was the son of Dr. L. K. H. Hackman, honorary secretary of the Portsmouth Division of the British Medical Association.

Johnson, Bernard Angus, Private 5th, Weald of Kent, Battalion of the Buffs, East Kent Regiment, elder son of George Lindsay Johnson, M.D., F.R.C.S., of 24, Wetherhall Gardens, Hampstead, killed in Mesopotamia on January 21st, aged 30.

Landale, James Russell, Captain 2nd Queen's Own Rajput Light Infantry, son of the late Deputy Surgeon-General James Landale, R.A.M.C. (retired), of Cheltenham, killed in Mesopotamia on March 8th, aged 34. He was born on December 6th, 1881, entered the Royal Scots Fusiliers as second lieutenant on January 8th, 1901, entered the Indian army, and was posted to the 2nd Q.O.R.L.I. on September 30th, 1905, and became captain on January 8th, 1910. He served in the South African war, in the operations in the Transvaal from May, 1901, to May, 1902, and received the Queen's medal with five clasps. His father died from an accident at Cheltenham on the same day that he was killed (see p. 470).

Langdon, Laurence, Lieutenant 14th Battalion Hampshire Regiment, attached 2nd Battalion Middlesex Regiment, second son of the late Thomas Charles Langdon, F.R.C.S., of Winchester, and of Broughton, Hants, died of wounds, in France, on March 14th, aged 41. His first commission was dated March 31st, 1915.

NOTES.

DR. DUNDAS GRANT is acting as surgeon in charge of the ear, nose and throat department of the New Zealand Military Hospital, Walton-on-Thames.

HONOURS.

The *London Gazette* of March 15th notifies the bestowal of a number of honours for service in the various expeditionary forces: Ten D.S.O.s, 78 Military Crosses, and 181 Distinguished Conduct Medals. Among the latter were three men of the R.A.M.C.: Sergeant W. E. Holdsworth, 1/2nd West Riding Field Ambulance; Private G. H. Needham, and Corporal W. Oliver, both of the 1/3rd West Riding Field Ambulance.

The King has bestowed the order of the Royal Red Cross on the following nurses, in consideration of their valuable services and devotion to duty on the occasion of the loss of the hospital ship *Anglia* on November 17th:—*First Class*: Mrs. M. S. Mitchell, Acting Matron, Queen Alexandra's Imperial Nursing Service (Retired List). *Second Class*: Miss A. Meldrum, Sister, and Miss E. A. Walton, Staff Nurse, Q.A.I.M.N.S. (Reserve).

Midshipman Charles Douglas Horsfall Herbert-Dixon, R.N., who was commended for action and who has been awarded the D.S.C. for services at Gallipoli, is the only son of Major Herbert-Dixon, O.C. 3/5th London Field Ambulance, and at his time of action was only 15½ years old.

MEDICAL OFFICERS WANTED.

2/1st South Midland Mounted Brigade.

Three medical officers are wanted to complete Brigade at present on East Coast. Applications to Major D. M. Spring, S.M.O., R.A.M.C.(T.), Head Quarters, Hempton, Fakenham, Norfolk.

India.

THE SCHOOL OF TROPICAL MEDICINE, CALCUTTA.

AN important step forward in the provision of a complete school of tropical medicine in Calcutta was taken on February 24th, when Lord Carmichael, Governor of Bengal, laid the foundation stone of the hospital for tropical diseases. It stands immediately to the south of the laboratories described and illustrated in the *JOURNAL* of March 7th, 1914. The chemical laboratory and the medical college adjoin, and the new eye hospital to be erected by the Government of Bengal will occupy a site facing the tropical hospital. The hospital when complete will consist of a basement and three floors. The ground floor will provide thirty-eight beds for Indian male patients. On the first floor there will be smaller wards of nine beds each for European males and Indian females, and of six beds each for European females and children respectively. There will also be twelve small single rooms for private patients and a theatre for clinical teaching and the few operations likely to be required. The second floor will be used temporarily for nurses' quarters until sufficient accommodation is available at the medical college hospital. Quarters are also provided on the top floor of the central block for a resident medical officer and a sister-in-charge, and in the turrets for two

Indian house-physicians. At first the hospital will contain eighty beds, but eventually thirty-six other beds can be provided on the third floor. Bathrooms, lavatories, pantries, and reading rooms are provided for each wing on both floors. In the north wing on the first floor there will be admission rooms, a clinical microscopical room, and a room for the sister. The funds for the erection of the hospital have been provided by public subscription. The laboratories and the hospital when complete will form a fine group of buildings on the new central avenue of Calcutta, which is being constructed by the improvement trust. The advantage of having the school, laboratories, and the hospital close together is too obvious to be insisted upon.

At the ceremony the Governor was received by the Surgeon-General of Bengal, Colonel Edwards, who said that the foundation and rapid progress of the school was due to the untiring energy of Sir Leonard Rogers. The first research scholarship in India would be attached to it, and would commemorate Dr. A. Mitra, who was a student first of the Calcutta Medical College and then in Edinburgh; he became chief medical officer at Cashmere, and finally home minister of that state. The scholarship had been founded by his widow.

Sir Leonard Rogers related the course of events which had led to the selection of the present site for the school and hospital. It had at first been proposed to appoint six professors, but this had to be cut down to four. Afterwards, however, the permission to lecture was given to Colonel Sutherland, I.M.S., imperial serologist. It was, however, felt to be unfortunate that a single professor should teach both protozoology and entomology, and as honorary secretary of the endowment fund he had made an appeal to the Rockefeller International Health Commission of New York. Dr. Victor G. Heiser, a member of the Commission and head of the sanitary service of the Philippine Islands, visited Calcutta, and after inspecting the new laboratories and seeing the great opportunities for research in the Calcutta hospitals, supported a request that the Rockefeller Commission should vote £1,500 a year to endow a separate professorship in protozoology. After the war, therefore, it would, he hoped, be possible to open the school with six professors, and he believed that medical men would be attracted not only from India, but from beyond its borders to the Calcutta School of Tropical Medicine. The response to the appeal for endowments by the jute, tea, and mining associations would warrant the appointment of three research workers, in addition to the scholarship founded by Mrs. Mitra. The hospital for tropical diseases was a necessary complement of the school. Though the subscription list was yet insufficient, he was able to look forward with hope now that the building had actually been commenced.

Lord Carmichael, after whom the hospital is to be named, then laid the stone, and in a short address recalled that it was exactly two years since he had laid the foundation stone of the laboratories. Hopes then expressed by Sir Leonard Rogers had since been fulfilled beyond expectation, in spite of unforeseen difficulties of great magnitude. Afterwards the company present inspected the laboratories of the tropical school.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

THE PROFESSION AND THE DEPARTMENT OF PUBLIC INSTRUCTION.

THE medical inspection of school children has been actively carried on by departmental medical officers for some years, and good work has been done in this direction. Now, however, the Government has decided to go a step further and to undertake the work of treating all the school children who have any physical defects. For this purpose they have advertised for the services of additional medical officers and specialists. This is regarded as the thin end of the wedge towards a complete system of nationalization of medical services, and a special meeting of the New South Wales Branch of the British Medical

Association was held on January 14th to consider the matter. At that meeting the following resolution was passed unanimously:

That the Association is strongly opposed to any of its members accepting any of the appointments as medical officers, ophthalmic surgeon, ear, nose, and throat surgeon, physician, under the Department of Public Instruction now being advertised, unless the Government gives sufficient guarantees that the treatment of the school children will be confined to those whose parents are unable to afford to pay for medical attendance of the kind indicated, and that the rights of private medical practitioners will be preserved; and that, the Minister having written to the effect that it is the intention not to make any discrimination on the ground of the financial circumstances of the children, the appointments be declared inimical to the interests of the profession.

This resolution has been sent to all the members of the Branch, and it has aroused the ire of the Minister of Education. He stated that he did not believe that the great bulk of the medical men would endorse this arbitrary action.

... The principal weapon used by the British Medical Association when in conflict with the lodges and friendly societies of this State was the refusal of its members to meet in consultation any medical man who accepted a contract with the friendly societies. This meant the absolute isolation and ostracism of the practitioner. I propose in this instance to meet any such action by inviting my colleagues to permit me to bring in a bill enacting that any licensed medical practitioner refusing to meet another qualified licensed medical practitioner in consultation without good cause shown shall have his own registration cancelled.

The Minister's bark is worse than his bite, and it is hoped that a satisfactory settlement of the question will be effected.

NATIONAL ASSOCIATION FOR THE PREVENTION AND CURE OF CONSUMPTION.

The annual general meeting of this association was held on January 27th under the presidency of Sir Philip Sydney Jones. The report referred to the material reduction in the staff of the association owing to the war, and to the heavy responsibility which had fallen on the dispensary nurse. There were 368 new patients admitted to the dispensary during the twelve months, and 174 old patients continued their attendances. The number of attendances was 9,708, and the actual number of patients under treatment on December 31st, 1915, was 186. Ninety-four patients were sent to the sanatoriums during the year, and the patients visited in their homes by the nurse was 386. Sir Philip Sydney Jones was re-elected president, and Dr. F. S. W. Zlotkowski vice-president.

England and Wales.

LIVERPOOL MEDICAL INSTITUTION.

A SPECIAL meeting was held on March 16th, in the afternoon, with the object of presenting the congratulations of the members of the Liverpool Medical Institution to Mr. Edgar A. Browne and Dr. George C. Walker on their attaining the jubilee of their membership of the institution. There was a good attendance and ladies were invited to be present at the ceremony, which was preceded by a formal welcome by the President and the two members to be honoured. Tea was provided during half an hour's conversation, and many old friends were present on this memorable occasion. The President, Dr. Charles J. Macalister, occupied the chair, and after letters of regret from the Lord Mayor and others expressing their unavoidable absence had been read, introduced the following resolution:

The members of the Liverpool Medical Institution tender to Mr. Edgar A. Browne and Dr. George C. Walker their hearty congratulations upon their completion of fifty years of membership of the society.

Mr. Edgar A. Browne, as surgeon to the Eye and Ear Infirmary and lecturer in ophthalmology in the University of Liverpool, has been in the foremost rank of those who have advanced the science of his speciality.

Dr. George C. Walker, as physician to the Bootle Borough Hospital, has conferred invaluable benefits upon the sick and suffering among his fellow-townsmen.

Both alike have shown unwearied devotion to clinical work. Dr. Walker has served the institution as vice-president, and Mr. Edgar A. Browne as member of council, secretary to the ordinary meetings, vice-president, and president, and the members desire to place on record their gratitude to and pride in these veteran members of the profession.

They express the hope that these gentlemen may each have many years of happiness with the gratification of being able to look back upon a life's work which has been continuous, effective, and appreciated both by their patients and in the counsels of the profession.

The President lightly touched upon the village of Bootle, at that time a seaside place for Liverpool townspeople, who used to bathe there. It was in such a village Dr. George C. Walker settled down as a general practitioner. Now Bootle was a town with mayor and council, and the shore had long since been converted into spacious docks. With the growth of Bootle a hospital was soon found to be a necessity, and Dr. George C. Walker became attached as honorary physician, which post he held for many years, and was now consulting physician. Later he devoted his skill to mental diseases, and resided in Southport for some time, and was still engaged in active practice there. Speaking of Mr. Edgar A. Browne, the President dwelt upon his wit and humour—ever sources of pleasure to all who heard him. His position in Liverpool as an eye specialist was so well known that it was unnecessary for him to elaborate this point.

Dr. T. R. Glynn, Professor of Medicine, in supporting the resolution, was reminiscent of the days of his youth and that of Mr. Edgar A. Browne, and of the many repartees in which Mr. Browne indulged on various occasions. Dr. Glynn bore testimony to his friend's kindness of heart, his critical acumen, and his excellent method of rendering his discourses, even on eye diseases, not only instructive, but highly entertaining, spiced as they were with quips and anecdote.

Dr. R. Caton, Emeritus Professor of Physiology in the University of Liverpool, spoke of the literary ability of Mr. Edgar A. Browne, and of the artistic gifts inherited from his father, "Phiz," who illustrated many of Charles Dickens's works; both in literature and art Mr. Browne was one of the foremost men in the city. His criticism of art in the widest sense was highly valued, and his opinion was constantly sought for by many in the artistic professions.

Mr. Thomas R. Bickerton, Ophthalmic Surgeon to the Royal Infirmary, gave an account of the work of Mr. Browne, not only as a medical student, but as a medical practitioner. Liverpool had been a gainer in every respect in possessing such a citizen. In the early part of his career Mr. Browne paid a good deal of attention to diseases of the skin, and his published papers in the *Liverpool Medical and Surgical Reports* in 1869 and later revealed not only correct clinical observation, but evidence of that critical faculty which had ever characterized his work. In ophthalmology the many papers Mr. Browne had published showed how wide his researches had been and how valuable his observations were to all who practise the speciality.

The resolution was carried by acclamation.

Dr. George C. Walker gratefully acknowledged the honour that had been paid him, and his reply was adorned with apt poetical quotation referring to the responsibilities of a medical man. No class of men were called upon to do so much for so little, but, although they could not expect their attention to be repaid, they had their own exceeding great reward in the knowledge that they were doing good. It was such a thought that had sustained him throughout his professional life, and this vote of congratulation was to him a ratification of his endeavour to carry out this high ideal.

Mr. Edgar A. Browne genially objected to being pelted with virtues which he asserted he did not possess. He recalled to mind the reason of his becoming a member of the Medical Institution. It was not due to his professional knowledge, but to the fact that he was proficient in swimming. So good was he said to be in the science and art of natation that he was invited to come in and draw up a set of rules and regulations for persons apparently drowned. In spite of, or perhaps on account of, this circumstance, he felt he had received much benefit from his membership, and to his friends and all present he tendered his warm thanks for the honour they had paid him.

Ireland.

At the nineteenth annual meeting of the Royal Victoria Eye and Ear Hospital, Dublin, it was stated that 1,534 in-patients were treated during the year, and that the average number of beds occupied was 98.70. In the out-patient department 7,573 new patients were registered. In November, 1914, ten beds were placed at the disposal of the War Office, and in October, 1915, the number was increased in response to a request. Viscount Iveagh defrayed the cost of the equipment of these beds through the Dublin branch of the British Red Cross Society.

The Newry Board of Guardians has refused to adopt the graded scale of salaries for dispensary doctors recommended by the Local Government Board in 1906. The guardians have recently been advertising, without success, for a doctor for one of the districts, vacant by the resignation of Dr. Irvine. A substitute has been appointed as locumtenent at four guineas a week.

Correspondence.

MEDICAL ARRANGEMENTS AT SUVLA LANDING.

SIR,—The criticism in Parliament upon medical military affairs has aroused public anxiety. I trust some of it may be allayed when people hear the experience of one who took part in the treatment of those who were wounded during the first three days of the landing at Suvla Bay.

I was on board H.M. hospital ship *Soudan*, her station was in the naval firing line, and she received the first men who were wounded on the first day of the landing. I was deeply impressed by the efficiency of the first aid which was rendered to these men. All the wounds were skilfully dressed, properly splinted; those cases that required it had received a dose of morphine, and a short and accurate account was written on a label which was attached to each man. Many of the severe cases were so well and carefully dressed that I felt confident in leaving them until I could find more time to go thoroughly into their troubles.

On shore I could see many kinds of shells bursting among our advancing troops, on the land behind them, and on the beach where the wounded were being collected prior to their embarkation for our ship.

Nothing could have been wrong with the organization which planned and accomplished the deliberate and correct treatment of the wounded in the midst of that devastation, from which there was then no shelter. It must be borne in mind that this organized effort included the successful co-operation of naval and military medical units.

A good deal of the criticism made on this subject is based upon ignorance. Some of my professional brethren have told me I ought not to have been sent to Suvla Bay, and that my right place was at home to attend the cases on their return to this country. I was in my right place at Suvla Bay, where I attended numberless cases with which the work of my life had trained me to deal, and to any one of which I would have been called to see, immediately, at my hospital in London. The organization was as right in sending me there as it was in bringing me home when the ship was carrying cases mainly of a medical nature.

While in Eastern waters I had plenty of opportunity to observe the arrangements made by the naval and military authorities for the rapid conveyance and final accommodation of the wounded men disembarked from our ship. I came to the conclusion that had I friends or relations among those wounded in the Eastern theatre of war, I should be satisfied that the right thing would be done to them.—I am, etc.,

London, W., March 18th.

G. LENTHAL CHEATLE.

THE PHYSICS OF A SURGICAL DRESSING.

SIR,—To my mind Major C. W. Duggan holds the key of the whole argument, namely, that antisepsis and osmosis should be our guides in treating wounds not aseptic. Provided the dressing is not left on the parts too long to become more of a menace than a benefit I consider

that the drier the wound is kept the better. It must be remembered that a dressing is a compromise, and in many superficial wounds the advantage lies in applying as little dressing as possible. Provided the parts are kept clean any kind of dressing, no matter how effective, is a hindrance; the wound will do better if left uncovered. With deep-seated wounds, or wounds other than superficial, the case is rather different. Here we are concerned with a foul opening leading down to tissues more or less damaged, and that treatment which removes the discharge most effectively whilst keeping the surface sweet will give the best result. It is not a matter of moist *versus* dry dressing, but rather one of effective disposal of a discharge loaded with deleterious agents which may reinfect the surrounding parts. No doubt a wet dressing covered with impermeable material, if the parts are thoroughly drained and the dressing not allowed to become saturated with discharge, may not do much harm; indeed, I believe the healing process may be hastened. But in such a case the dressing should be renewed sufficiently often to keep the surface of the wound antiseptic; the frequency will depend upon the depth and character of the wound and the thoroughness with which antiseptics are brought into contact with the infected focus.

If the wound is septic, make it aseptic. Frequently we cannot attain to this perfection, but in all circumstances this end must be kept steadily in view, for until the wound becomes aseptic there can be no true healing process.

In general practice many so-called discoveries of to-day and yesterday have been in use time out of mind, and Sir Almroth's saline treatment of wounds amongst others. I know that my neighbours in Yorkshire, like myself, have used it for long. I have discarded impermeable coverings for dressings for a great many years. I very soon discovered their danger in a wide practice where patients cannot be seen every few hours.

I give this instance of the ineffectiveness of an impermeable dressing over a wound. An armourer-sergeant belonging to this town was sent home suffering from a septic finger which had been treated for more than a month. The finger had the usual wet dressing covered with impermeable oiled silk. I gave it a very thorough washing with a weak antiseptic, clipping away all dead skin, and clearing out the wound as well as I could, and then put it up in a dry dressing. It healed almost directly.—I am, etc.,

Helmsley, March 4th.

ALEXANDER BLAIR, M.D.

THE PRICE OF DRUGS.

SIR,—Is it not time that some effort was made by combined effort to do something to reduce the present price of drugs? It is a very serious matter for general practitioners who dispense their own medicines, and in my own case it had caused a 50 per cent. increase in cost during the last year.

One cannot possibly do without bromides and salicylates and many other drugs which at the present time are enormously increased in price.

Our Association should at once make representation to the Government and make an effort to induce private firms to set about manufacturing drugs that have previously been made in Germany. If there is anything whatever in the cry that after the war we shall boycott German products there ought to be no delay in guaranteeing the firms against any loss on their outlay in plant.—I am, etc.,

Buckingham, March 7th.

ARTHUR E. LARKING.

Universities and Colleges.

UNIVERSITY OF DURHAM.

The following candidates have been approved at the examinations indicated:

FIRST M.B. (*Elementary Anatomy and Biology, Chemistry, and Physics*).—R. L. Dagger, *R. C. Brown, T. H. R. Anderson, N. R. Beattie, Dorothy O. S. Blair, Nan Coxon, H. L. Mather, R. P. Wantless, Philomena R. Whitaker. *Elementary Anatomy*: M. J. Erdberg, Kun Piu Leung, May Raw, R. Sanderson. SECOND M.B. (*Anatomy and Physiology*).—J. M. Brydson, *J. R. Hughes, S. Raj Chatterji, S. (Rev.) Foskett, I. Giris, S. E. Goulstine, J. P. Higham, D. Levinstein, Habib Toma, H. W. Walther, G. R. Woodhead. (*Anatomy*).—Iris M. Cheeseright.

* Honours—Second Class.

Obituary.

THEODORE THOMSON, C.M.G., M.D.LOND.,
D.P.H.CAMB.,

FORMERLY ASSISTANT MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.

By the death of Dr. Thomson at the comparatively early age of 57 the public health service has lost a first-class epidemiologist and sanitary administrator. The son of the Rev. Wm. Thomson, of Belhelvie, Aberdeenshire, he was one of a large family, several members of which have taken important positions in the profession of medicine. He studied at Aberdeen, Edinburgh, and London, taking the degree of M.D.Lond. in State Medicine in 1892 and the D.P.H.Camb. in 1888. His first public health appointment was that of M.O.H. to the city of Aberdeen in 1886, which appointment he resigned after less than two years' service to take a similar post at Sheffield. During the small-pox epidemic at Sheffield, which prevailed during 1887-8, he was in charge of the administration of the public health service of the town, and his ability as an administrator was brought to the notice of the Local Government Board by the late Dr. W. F. Barry, whose report on the outbreak is so well known. Dr. Thomson joined the staff of the Board as a medical inspector in 1891, and continued in the service of the Board until his retirement, owing to continued ill health, in 1913.

He was at first engaged in numerous inquiries on the causation of outbreaks of disease, particularly on outbreaks of enteric fever at Maidstone, Worthing, Newport (Isle of Wight), Chichester, Swinton and Pendlebury, and many others. His conclusions were in all cases logical deductions from the facts, and if no conclusion could be come to he at once admitted this, and did not shirk the issue by bringing forward surmises or unsupported hypotheses. Thus, in his report on recurrent prevalence of enteric fever in the Folkestone urban sanitary district during the years 1896-1900, he admitted that the fever could not be explained on the known facts. At the same time he drew attention to the presence of the same milker at each of three farms the milk supplied from which was suspected as the medium of infection. It was not until the continued prevalence of fever at Folkestone was again investigated in 1909 by his lamented colleague, the late Dr. R. W. Johnstone, that it was ascertained that this milker was an enteric fever "carrier," and had for fourteen years been producing the fever. These occurrences caused him subsequently to devote a large amount of work to the investigation of the effect of "carriers" in disseminating enteric fever; and in conjunction with Dr. J. C. G. Ledingham extensive inquiries were made as to the proportion of carriers among convalescents, the duration of their infectivity, and other matters. If it had not been that his health broke down there is no doubt that he would have dealt with the whole subject in a comprehensive report. As his experience increased he was engaged on various important Commissions; he was placed on the committee of inquiry into the public health of the city of Dublin and was appointed delegate for England at the International Sanitary Conferences at Paris and Rome in 1903, 1906, and 1907. In 1904 the prevalence in the West Indies of small-pox of a very mild type, such that the nature of the disease even was often in doubt, led to great difficulties, owing to the differing quarantine regulations of the various islands. Dr. Thomson was sent out to endeavour to settle this question, to secure the adoption of some uniform procedure, and to reorganize the sanitary administration. In this he succeeded. In 1906 he was sent on a special mission to advise on the sanitary defence and administration of the Persian Gulf, in conjunction with the Powers interested in this region, especially for the prevention of the importation of exotic disease from the shores of the Persian Gulf to other countries. For his services to the Colonial and Foreign Offices he received the C.M.G. From this time he became more and more engaged in the prevention of importation and spread of diseases of an exotic nature, an important part of the work of the Local Government Board which perhaps is not generally known to the public. He was frequently consulted by the Colonial and Foreign Offices on such subjects as cholera, plague, yellow fever, and colonial sanitary

administration in general. For some years he was a member of the West African Medical Advisory Committee, and was British representative on the International Office of Health and Public Hygiene, the head quarters of which are at Paris. There was, however, one important disease which is endemic and epidemic in this country to which he devoted much attention, and his report "On measles in England and Wales, and measures which may be or have been adopted by sanitary authorities for controlling this disease" forms a classic on the subject. He showed that although a number of authorities had adopted the compulsory notification of this disease, this notification had not been properly followed up by visits of advice to the parents, provision of nursing assistance in the homes for cases needing it, provision of medical attendance under similar circumstances, nor the provision of hospital treatment of cases which could not be properly looked after at their homes. Owing, as was believed, to lack of these provisions, the result of notification was very disappointing, and there was no reduction in the excessive mortality from this disease, which causes such a waste of infant life. The recent Order of the Local Government Board empowering sanitary authorities to provide all these desiderata for dealing with measles may be looked upon as the fruit of his work in this direction. In 1911 Thomson succeeded the late Dr. H. Franklin Parsons as assistant medical officer to the Board, and from this period until his retirement early in 1913 his time was taken up in administrative work.

Of striking presence, clear intellect, polished and suave in manner, with a good knowledge of the French language, Thomson was marked out for a diplomatist. Fond of company, devoted to golf, he had a large circle of friends; he never married. His services were readily available to all applicants, and he never appeared to be too busy to devote any amount of time to the assistance of any investigator who might ask his advice on public health matters; but there can be no doubt that for years he worked too hard and overtaxed his physical powers. His retirement was a great loss to the Local Government Board, and other departments of the State will no doubt miss his wise and prudent counsels.

SIR CHARLES BALL, BT., F.R.C.S.

We regret to record the death of Sir Charles Bent Ball, Bt., M.D., M.Ch., F.R.C.S., which occurred on March 17th at his residence in Dublin.

The late Sir Charles Ball was a surgeon of great eminence, and his abilities caused him to be held in high respect not only in Ireland but throughout the United Kingdom. He was born in 1851, and was the youngest son of the late Robert Ball, LL.D., and brother of the well-known astronomer. Sir Charles Ball received his education at Trinity College, Dublin, and from his entrance to the medical school of the college in 1870 his career was a series of rapid successes and distinctions. In 1871 he was a senior moderator, and graduated B.A.; in 1872 he gained the Senior Medical Exhibition and Travelling Prize. In that year also he took the degrees of M.B. and M.Ch., while three years later he became M.D. He studied also in Vienna. He became a Fellow of the Royal College of Surgeons of Ireland in 1879, and in 1900 received the honorary Fellowship of the Royal College of Surgeons, England. Two years later he gave some lectures at San Francisco, and in 1903 was Erasmus Wilson Lecturer to the Royal College of Surgeons. He published a number of papers in the medical journals and transactions, and was the author of a well-known book on diseases of the rectum and anus, a second edition of which appeared in 1896. He described a special operation for the cure of pruritus ani which is commonly spoken of by his name. Among the numerous appointments held by Sir Charles Ball were those of Honorary Surgeon to the King in Ireland, Regius Professor of Surgery in the University of Dublin, President of the Royal Academy of Medicine, Ireland, Lord Chancellor's Consulting Surgical Visitor in Lunacy, and medical referee for Dublin City and County under the Workmen's Compensation Act. He was the representative of Dublin University on the General Medical Council, and a Past President of the University Biological Association. In addition to being consulting surgeon to various Dublin hospitals, he was

visiting surgeon to Sir Patrick Dun's Hospital; he was also consulting surgeon to the Masonic Girls' School and Simpson's Hospital. His practical skill as a surgeon was equal to his attainments and knowledge, and it will be remembered that it was Sir Charles Ball who operated upon Lady Dudley during her serious illness when Lord Dudley was Lord Lieutenant of Ireland.

Soon after the outbreak of war Sir Charles Ball was made a temporary lieutenant-colonel R.A.M.C., and was frequently present at the disembarkation of wounded soldiers brought to Dublin, even on occasions when severe weather and early hours made attendance trying for a man of his years. At one time he was a member of the Advisory Board for the Army Medical Service. He was president of the Leinster Branch of the British Medical Association in 1903, and of the Section of Surgery of the annual meeting in 1905, when the Association met in Leicester. Sir Charles Ball was also a president of the Royal Zoological Society of Ireland, and took a keen interest in the work of this society for many years. He was knighted in 1903, and in 1911 was created a baronet.

ODILLO MAHER, M.D.,

OPHTHALMIC SURGEON TO THE SYDNEY HOSPITAL.

Our correspondent in Sydney, New South Wales, writes: By the death of Dr. Odillo Maher, of Sydney, which occurred at Hobart, Tasmania, on January 10th, from acute pneumonia, the medical profession in Sydney has lost one of its leading members. He was born in Sydney in 1858, and was educated at St. Mary's College, Lyndhurst, and at St. Patrick's College, Goulburn. After spending a year at the Sydney University he went to Ireland, and in 1881 he took the degrees of M.D., Ch.M. at the Royal University. In the following year he obtained the diploma of M.R.C.S.Eng. He early devoted his attention to ophthalmology, and was appointed house-surgeon to Moorfields Hospital, and later became clinical assistant at the same hospital. On his return to Sydney he began practice as an ophthalmic surgeon. In 1886 he was appointed honorary ophthalmic surgeon to the Sydney Hospital, and also to St. Vincent's Hospital, Sydney; both positions he retained up till the time of his death. He was also examiner in ophthalmology in the Sydney University. He occupied several important positions at different times. He was President of the Eye Section at the Australasian Medical Congress in Adelaide in 1905; he was a member of the Council of the New South Wales Medical Union for many years, and a member of the New South Wales Medical Board for the last two years. He was a Fellow of St. John's College within the University of Sydney, and was recently appointed a member of the consulting staff of the Military Base Hospital at Randwick, Sydney.

In 1894 he was one of the victims of the serious railway accident at Redfern, and was severely burnt about the hands and face. This necessitated a prolonged absence, and it was feared that he would never be able to resume his work as an operating ophthalmic surgeon. Fortunately this unfavourable opinion proved to be incorrect, and he resumed full work after an interval of two or three years. He contributed many important articles to the medical journals on his own speciality.

The funeral at Waverley cemetery, preceded by a Requiem mass at St. Mary's Cathedral, was largely attended. He leaves a widow and a family, one of his sons having but recently graduated in medicine at the Sydney University.

DEPUTY SURGEON-GENERAL JAMES LANDALE, R.A.M.C. (retired), died at Cheltenham on March 8th, aged 79. He had dined out on the evening of March 7th, and, walking home, stumbled over an obstruction in the dark and fell. He was assisted home, and did not seem to have been seriously injured, but passed away in his sleep during the night. He was educated at Edinburgh University, where he took the degree of M.D. in 1856 and the L.R.C.S. Edin. in the same year. He entered the army as assistant surgeon on September 15th, 1857, became surgeon in 1869, and surgeon-major in 1873, retiring as deputy surgeon-general on December 10th, 1892. He served in the Indian Mutiny in 1858-59 with the 92nd Foot, and was present at the actions Rahatgarh, Mangrauli, Sindwaha, Kurni, and

Baroda, and received the Mutiny medal. By a sad coincidence his son, Captain James R. Landale, was killed in action in Mesopotamia on the day of Deputy Surgeon-General Landale's death.

LIEUTENANT-COLONEL ROBERT ALEXANDER PETER GRANT, R.A.M.C. (retired), died at Reay House, Inverness, on March 8th. He took the M.R.C.S. in 1858 and entered the army as assistant surgeon on June 13th, 1859, becoming surgeon in 1871, surgeon-major in 1873, and retiring with a step of honorary rank on July 2nd, 1884. He served in the New Zealand war of 1863-66 in the province of Terawaki, was mentioned in dispatches in the *London Gazette* of October 20th, 1865, and received the medal.

SURGEON-MAJOR EDMUND JOHN HOSKINS, Bengal Medical Service (ret.), died in London on January 22nd, aged 79. He was educated at St. Bartholomew's, and took the diplomas of M.R.C.S. in 1858 and L.S.A. in 1859, and the degree of M.D. at St. Andrews in 1860. He entered the Indian Medical Service as assistant surgeon on October 1st, 1860, became surgeon on October 1st, 1872, and surgeon-major on July 1st, 1873, retiring on April 7th, 1879. The *Army List* assigns him no war service.

We regret to announce the death of Dr. DAVID W. CHEEVER, which occurred at his house in Boston on December 27th, at the age of 84. He graduated at Harvard in 1852 and was one of the original surgical staff of the Boston City Hospital which was opened in 1864. He had been a teacher at Harvard since 1860 when he was appointed demonstrator of anatomy. He became professor of clinical surgery in 1875 and professor of surgery in the Medical School in 1882. On his retirement in 1893 he received the title of emeritus professor. He was president of the American Surgical Association in 1889 and the author of *Lectures on Surgery* and of more than sixty papers and addresses on professional topics. He reported more than 1,200 major operations performed by himself, with 85 per cent. of recoveries.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Professor Gilbert-Ballet, of Paris, one of the foremost authorities on mental disease in France; and Dr. Léon Labbé, senator for the Orme department, and member of the Institute of France, whose name is associated with a successful operation on a man who had swallowed a fork, aged 83.

Medico-Legal.

WORKMEN'S COMPENSATION FOR RHEUMATISM.

Glasgow Coal Company Ltd. v. Welsh.

THE House of Lords on March 6th gave judgement on an appeal from the Second Court of Session in Scotland which raised a point of some novelty under the Workmen's Compensation Act, 1906.

The facts were as follows: One, Welsh, was a miner employed as a brusher at the Glasgow Coal Company's colliery. On October 23rd, 1914, the water pump broke down and a large quantity of water accumulated in the pit bottom. Work was suspended, and five days later Welsh was directed to go down the pit. He went down in the belief that he was going to do his ordinary work as a brusher, but, in fact, on reaching the pit bottom he was told off to bale the water. On this work he was engaged up to his chest in water for eight hours.

During the next day or two he felt great stiffness and cold and pains in his joints, but continued to work till the morning of November 2nd. On November 3rd he consulted a doctor, who found that he was suffering from subacute rheumatism. On January 26th, 1915, he returned to work but was unable to earn his full wages, and his incapacity did not wholly cease until March 2nd, 1915. During the whole of this time he was suffering from rheumatism caused by the extreme damp and exposure to which he had been subjected.

The Sheriff Substitute had found that this was an injury caused by accident "arising out of and in the course" of Welsh's employment, and made an award in his favour.

Viscount Haldane, in his speech, said that the question was whether, upon the above facts, the event could be, in point of law, an accident within the meaning of the Act. He thought that had Welsh died suddenly while so exposed there could be no doubt that that would have given a title to his dependants

to claim on the footing of injury from accident, and he was unable to see why a claim in respect of a less serious mishap should be excluded by the circumstance that the miscalculated action of entering the water took time to produce its consequences. In his judgement that miscalculated action of entering the water must be taken to have constituted a definite event which culminated in rheumatic affection and to have imported into that event the character of an accident within the meaning of the Act.

The other lords concurred, and the appeal was dismissed.

The Services.

INDIAN MEDICAL SERVICES.

It has been decided that the outfit allowance of Rs. 600, notified in India Army Order, No. 122, dated March 22nd, 1915, shall be granted to all I.M.S. officers in permanent civil employ (including those who have officiated for three years in civil employment) who reverted to military duty, during the present war, prior to the issue of India Army Order, No. 546, dated October 11th, 1915.

EXCHANGE DESIRED.

TEMPORARY LIEUTENANT, anaesthetist to a base hospital in France, wishes to exchange with officer similarly employed in London or neighbourhood. - Address No. 1250, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

THE Wellcome Historical Medical Museum, Wigmore Street, will be closed for cleaning during the whole of the month of April.

PROFESSOR J. MARTIN BEATTIE, M.D., will open a discussion on tuberculous diseases of children and the milk supply at a provincial meeting of the Royal Sanitary Institute to be held at the University of Liverpool on March 31st at 3.30 p.m.

APPLICATIONS from hospitals within nine miles of Charing Cross, and from convalescent homes and sanatoriums for consumption taking patients from London, to participate in the grants made by King Edward's Hospital Fund for London must be received at 7, Walbrook, London, E.C., before March 31st.

IN response to the request of a First Aid Conference held at Washington in August, 1915, President Wilson has appointed a board of standardization to investigate first aid methods, packages, and the standardization of equipment, and to draw up a uniform course of instruction to be given throughout the country.

THE late Mr. Stanley Boyd left estate valued at £32,646. After providing for certain legacies he left the residue of his property in trust for his mother and sister and the survivor of them, and subject thereto he gave £2,100 to Epsom College for one foundation scholarship, and the ultimate residue to the University of London for the endowment of a professorship of pathology in the Medical School of Charing Cross Hospital. Out of the property bequeathed to him by his wife he gives a number of legacies to her relatives, £1,000 each to the London School of Medicine for Women, the New Hospital for Women, and the Pathological Department of the New Hospital for Women, and any residue to the New Hospital for Women.

THE Military Education Committee of the University of London has presented its annual report for 1915. The medical unit was in camp for its annual training during the summer vacation on Salisbury Plain. Arrangements have been made for camp training during the other vacations, and for periods of intensive training in preparation for the special examinations for certificates A and B held for cadets of this unit. Upon the announcement of the War Office's decision in regard to the younger medical students taking combatant commissions, a considerable number of medical cadets transferred to the artillery and infantry units. Three former officers of the University of London O.T.C. (of whom one was an ex-cadet), eighty-six former cadets, and one other officer recommended for his commission by the university have fallen in the war. A number of honours, including one Victoria Cross, have been awarded to officers and cadets of this corps.

WITH the *St. Bartholomew's Hospital Journal* for March is published, under the title *St. Bartholomew's and the War*, a second supplementary list, made up to February 16th, 1916, of those connected with the hospital and medical school who are serving in the navy, army, and territorial force. It brings up the number to over 1,600. Five, of

whom two were serving in the R.A.M.C. (Lieutenant Brunton and Lieutenant Garrod, both sons of members of the staff of the hospital), were killed in action; six, of whom two were in the R.A.M.C., have died of wounds; three, all in the R.A.M.C., have died; eleven, of whom seven were in the R.A.M.C. and one in the I.M.S., have been wounded. The good services rendered by many others have been recognized in dispatches and by promotions and decorations. The list is illustrated by portraits of many of those who have been killed, or died; among the portraits is that of Miss Buckingham, who died as matron of the 2nd Birmingham War Hospital. The list contains the names of forty-four other present or former nurses of the hospital who are serving with the armies at home or abroad.

SPECIAL meetings of the Central Midwives Board were held on March 15th and 17th. Reports on 7 adjourned cases resulted in no action being taken in 5; 1 case was further adjourned for three months, and 1 woman was struck off the roll. Of the 14 fresh cases, 1 midwife was severely censured, judgement on 2 others was postponed for reports in three and six months, and 11 women were struck off. Neglect in cases of ophthalmia neonatorum, puerperal fever, and pemphigus were among the most serious charges, but there was one of signing a false certificate of stillbirth; as usual, there were a number of cases of ignorance of the use of the clinical thermometer, inability to take the pulse, want of cleanliness, etc. The Board held its monthly meeting on March 16th. In reply to a letter from the General Medical Council regarding an alleged case of "covering" an uncertified woman by a registered medical practitioner, the Board, in forwarding the papers to the Council with a request that it will take such action in the matter as it may see fit, expressed its readiness, if so desired, to appear as prosecutors in the case. The Standing Committee, having completed the revision of the rules after carefully considering suggestions for their amendment sent by local supervising authorities, medical officers of health, etc., decided to ask the Privy Council to approve the same and order that the new rules shall come into force on July 1st next for a period of five years. Sir Francis Champneys presided at all three meetings.

AT an inquest held recently at Wigan on an illegitimate child Mr. H. Milligan, the Wigan Borough Coroner, made some remarks reflecting on the medical man who had attended the child and who gave the death certificate. Not content with that, the coroner proceeded to make observations which can only be interpreted as an attack on the Wigan medical profession generally. In the case in question the statement of the woman who had charge of the child was to the effect that the child had suddenly appeared to be choking, and she had run with it to the doctor, who said it had croup, and gave medicine and certain directions for treatment. Next day the child was worse, and the doctor was sent for, and was said to have promised to go, but failed; the child died later in the day without having been seen again by the doctor, who gave a certificate of death from bronchopneumonia. On this one-sided evidence the coroner based his attack on the doctor, and made it a text on which to deliver a homily to the Wigan profession. As only too frequently occurs in coroners' courts in certain districts, the doctor's side is not given. He may have had perfectly satisfactory reasons for not carrying out his promise to visit, if he ever made it, and if the coroner had had any proper sense of fairness he would have seen that the doctor's side of the question was made as public as he asked the press to make the other side. According to the newspaper report, the coroner, after noting that the doctor had said that the child had croup, and yet gave a certificate of bronchopneumonia, added: "It made it very difficult to know where they were when they had such contradictory statements." The public have a right to demand that coroners who venture to criticize in such matters should have at least an elementary knowledge of what they are talking about. If the coroner had read in the official book of death certificates the instructions to medical practitioners as to the terms to be used in death certificates, he might have seen the injunction: "Avoid using the word 'croup' at all." If, as appears probable, the coroner's remarks about the Wigan medical profession in general are as unfair as his remarks about this particular case, the "higher authorities" to which he threatens to make complaint might well be asked to decide the additional question whether the coroner is not deserving of censure for thus displaying a want of acquaintance with the terms to be used in death certificates and for his one-sided treatment of the medical profession.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

THE telegraphic addresses of the **BRITISH MEDICAL ASSOCIATION** and **JOURNAL** are: (1) **EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Antology, Westrand, London*; telephone, 2631, Gerrard. (2) **FINANCIAL SECRETARY AND BUSINESS MANAGER** (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) **MEDICAL SECRETARY**, *Meditsecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

QUININE COLLYRIA.

DR. B. W.—Quinine sulphate is only soluble in water to the extent of 1 in 800, therefore it is not possible to get a clear solution of 1 per cent. strength without the addition of acid, and if this were added the solution causes unnecessary pain. Quinine hydrochloride is soluble in water to the extent of 1 in 40; if, therefore, this salt be used, a clear bland solution of even 2 per cent. strength can be obtained. An even stronger and quite unirritating solution can be made by using the acid hydrobromide of quinine, which is soluble in water to the extent of 1 in 7. The hydrochloride is usually the more easily obtained. It may be added that cocaine has no curative value—in fact, aqueous solutions are injurious to the normal corneal epithelium, tending to cause exfoliation; consequently the healing of corneal lesions is delayed by its exhibition.

ANSWERS.

THE TREATMENT OF PRURITUS ANI.

DR. C. P. BURD (Upton-on-Severn) writes, in answer to "A. E.," to suggest that the patient be instructed to give himself a cold water enema each night before going to bed and to leave off all other aperients for a time.

DR. A. WINKELRIED WILLIAMS (Dermatologist, Royal Sussex County Hospital, Brighton) writes: Post-operative pruritus ani is frequently a nocturnal plague. A point in the management of these cases, not mentioned in most papers on the subject, is for the patient to acquire the habit of stooling just before going to bed. A small faecal mass in the rectum near the internal sphincter, or the site of an old operation, will light up a bout of itching, and its removal will often give a night of perfect freedom. The habit is to some patients rather difficult to acquire and a suppository may at first be required, and some find it inconvenient to habitually empty the rectum twice in twenty-four hours. In eczematous cases the time-honoured directions to wash with cold water after stooling does not always agree, and a mild antiseptic grease generally gives a better result; an ointment of hydrarg. oxid. flav. 2 grains, vaselin. flav. 1 ounce, should be freely applied to the anal region and just inside the external sphincter before stooling and used freely in after-cleansing. An efficient temporary remedy for bouts of intolerable pruritus is acid carb. 60 grains, ol. olivae 2½ ounces; in many cases it acts better and more rapidly than cocaine and is much safer.

LETTERS, NOTES, ETC.

NEED FOR RESIDENT SURGICAL OFFICERS AT HOSPITALS.

THE Central Medical War Committee invites applications from gentlemen of good hospital surgical experience, who, being over age or otherwise disqualified for service in the R.A.M.C., would yet be willing, if the necessity arose, to take appointments as resident surgical officers in hospitals. This appeal is not intended to interfere with the ordinary announcements of vacancies for such posts, but the Central Medical War Committee would like to have in reserve a supply of experienced surgeons who would, if necessary, be prepared to fill such appointments for a time. Applications should be sent to the Secretaries, Central Medical War Committee, 429, Strand, London, W.C.

THE DIAGNOSIS AND TREATMENT OF DIPHTHERIA.

LOCUM writes: As a locumtenent of considerable experience in many parts of England, I feel it my duty to call attention to a subject of very great importance both to the credit of the profession and the interests of the community—namely, the diagnosis and treatment of diphtheria. Nearly every practitioner with whom I have discussed the subject is more or less a law unto himself, and there appears to be no safe anchorage wherein to trust unflinchingly in the treatment of an illness giving rise at all times to great anxiety to all concerned. One practitioner does not believe in serum at all, and distrusts at times the accuracy of the positive microscopic report. Another is content to give the antitoxin by the mouth, and

is convinced that he has got quite as good results from that method of administration, and that a favourite mixture given is sufficient treatment locally for the throat. Another gives subcutaneously 2,000 units of serum, and is more or less content to rest on his oars. Another I know of gives 8,000 or 12,000 straight away, and declares that anything less is useless. Still another says that by the administration of antitoxin a mysterious and deleterious negative phase is set up. And yet another has written that serum may be positively dangerous. Such a diversity of opinion is necessarily bewildering to the man who perhaps only sees an occasional case.

Of course one realizes that the severer cases will demand the more heroic treatment, but then it is not always easy to say when a case is, or is going to be, severe or not. In the obviously severe cases there is less difficulty, for in my experience, apart from the obviously dangerous constitutional symptoms, the amount and extent of membrane is not always a sure guide to severity. I think that if some practitioner of large experience would give us his precise methods of treatment, and a few hints on early diagnosis in doubtful cases, whilst the swab is on its journey or when it need not be sent, it would be a very real help; for prophylactic serum administration, although in my opinion the ideal and proper treatment, may not always be acceptable in the case of parents with a limited education, especially if it turns out to be simple tonsillitis, although I must say that when the position is put wisely before them they nearly always take the common-sense view; but these are just the cases in which the dosage of antitoxin presents the greatest difficulty, as time is recognized to be a factor of such vital importance.

WHAT DETERMINES SEX?

DR. STEPHEN M. LAURENCE (Trinidad, B.W.I.) writes: The following case, which recently came under my notice, might prove of interest. Mrs. P. is a vigorous-looking woman of 40 years. She has been married three times, and has had fifteen children—all boys. She gave her history as follows: She married very early, and had her first child, a boy, at 15 years of age. He is alive and well, aged 25. She had five other boys by her first husband, six in all. They were all born dead before the eighth month was completed (evidently she had developed syphilis). This husband had no other children. She bore her second husband five boys—the first three being born dead, the last two are still alive. This husband had two children by another mother—one boy and one girl. From her third marriage there are four boys. All of these are alive. The last husband has two other children—a boy and a girl. The woman here is the constant factor, the resulting sex being the same in fifteen consecutive pregnancies to three different men, two of whom had girls by another mother. The number of husbands and the unusual number of children seems to preclude mere accident.

DECREASE OF MEDICAL PUBLICATIONS.

THE annual report of the Library Committee of the Philadelphia College of Physicians for 1915 states that the total number of volumes in the collection, including 10,237 unbound Reports and Transactions, was 107,782. The number of unbound theses and dissertations was 12,949, and of unbound pamphlets 90,670. The total increase in the number of volumes during the year was 2,085. Owing to the war about 250 periodicals ceased to reach the library, while some twenty others were received at irregular intervals. Most of the books received, other than English or French, came through Amsterdam; no theses or dissertations were received from the war zone. In comparison with the number of new publications received in 1913, there was in 1915 a decrease of about 90 per cent. of the books published in French, about 69 per cent. of those issued in German, and about 34 per cent. in British publications.

BOLD ADVERTISEMENT.

MUCH has been heard of the commercial enterprise of Germany, and her newspapers are now boasting that she will quickly recover the trade lost owing to the war. Perhaps it is not sufficiently realized that German success in this, as in other fields, is largely due to sheer impudence. A curious example is given in the *Chronique Médicale* of February 1st. It is there stated that a number of French doctors have received from a Stuttgart firm of manufacturers of artificial limbs a catalogue of its wares with an offer of a large discount on the usual prices. Surely such an offer could only have come from Germany.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE TOXICOLOGY OF SALVARSAN:

DIOXYDIAMIDO-ARSENO-BENZOL (SALVARSAN OR KHARSIVAN).

BY

WILLIAM HENRY WILCOX, M.D.LOND.,
B.Sc.LOND., F.R.C.P.LOND.,LIEUTENANT-COLONEL R.A.M.C.; PHYSICIAN TO OUT-PATIENTS,
ST. MARY'S HOSPITAL, LONDON; SENIOR SCIENTIFIC
ANALYST TO THE HOME OFFICE;

AND

JOHN WEBSTER, F.I.C.,

ASSISTANT SCIENTIFIC ANALYST TO THE HOME OFFICE; DEMONSTRATOR
OF PATHOLOGICAL CHEMISTRY TO ST. MARY'S HOSPITAL
MEDICAL SCHOOL, LONDON, W.

Dioxydiamido-arseno-benzol dihydrochloride is the chemical name for a most valuable therapeutic remedy, and it is better known by the name "salvarsan," or "kharsivan"—the latter denoting the English preparation.

Salvarsan was introduced by Professor Paul Ehrlich in 1910, and neo-salvarsan in 1912. They were also known by the respective numbers "606" and "914," these denoting the numerical position of the compounds in the list of chemical substances prepared and experimented upon.

On the outbreak of war it was found desirable that dioxydiamido-arseno-benzol should be manufactured in this country. The preparation of this important remedy was satisfactorily carried out, and it was introduced under the name of "kharsivan." Before being placed on the market samples of kharsivan were submitted to careful chemical and physical tests, and these gave practically identical results with salvarsan.

Physiological and therapeutic tests were carried out by one of us (W. H. Wilcox) at the request of the Board of Trade, and it was found that the English preparation was practically identical in its physiological and therapeutic effects with salvarsan. The toxic action of kharsivan was certainly not greater than that of salvarsan.

Kharsivan was then definitely introduced after the sanction of the Board of Trade had been received. The testing of kharsivan after its introduction was entrusted to the Medical Research Committee, who have submitted samples of every batch prepared to searching physiological and toxicological tests.

USES.

Syphilis.

Salvarsan, or kharsivan, has become definitely established as the most effectual remedy for the treatment of syphilis.

The recent discovery in 1905 of the causal agent of syphilis—namely, the *Spirochaeta pallida*—has enabled this organism to be demonstrated in the lesions associated with syphilis. The special serum test—the Wassermann reaction—published in 1906, enabled the presence of a syphilitic infection to be demonstrated in the blood serum, and in the cerebro-spinal fluid in cases where the central nervous system was involved.

The therapeutic effect of any antisyphilitic remedy can be definitely estimated by the application of tests for the presence of the specific organism in syphilitic lesions, and by the application of the Wassermann reaction to the blood serum.

It is by these tests that it has been definitely proved that salvarsan or kharsivan are the remedies which occupy the foremost place in the treatment and cure of syphilis.

It is unnecessary to emphasize the importance of these remedies from a prophylactic point of view, since the rapid destruction of the infective agent in the body means the prevention of spread of infection.

Other Spirochaete Infections.

Other spirochaete infections, such as relapsing fever in man, due to a spirochaete infection; recurrent fever in animals, due to spirochaetes; and spirillose infection of birds, respond equally well to the administration of salvarsan or kharsivan in proper doses.

Yaws is a disease due to a spirochaete infection, and this responds rapidly to treatment with salvarsan or kharsivan.

Mycosis fungoides and glandular conditions resembling syphilis have shown marked benefit after treatment with salvarsan or kharsivan.

Tertian malaria has been cured by the administration of these remedies, but *quartan malaria* does not seem to respond to treatment in the same way.

Salvarsan, or kharsivan, has been used with benefit in leukaemia, pernicious anaemia, lymphadenoma, trypanosomiasis, anthrax, psoriasis, and lichen planus, but the effect has not been of so marked a degree as in the spirochaete infections above named.

CONSTITUTION AND PROPERTIES.

Salvarsan, or kharsivan, has the chemical formula:

This may be expressed graphically thus:

Salvarsan is seen to be a complex compound of arsenic with the benzene nucleus.

It was evolved after a great deal of experimental work extending over a number of years. Koch had found that ordinary antiseptic drugs which were of high value outside the body were useless *in vivo* since they had as powerful a toxic action on the organism as on the parasite; or otherwise expressed, their organotropic action was equal to their parasitotropic action. Ehrlich endeavoured to find a drug which had as high a parasitotropic but as low as organotropic action as possible. He found that the best results were yielded by compounds of arsenic with the benzene nucleus.

Atoxyl was an example of one of these compounds. Its constitution is expressed by the formula:

Koch found that this drug was markedly parasitotropic in sleeping sickness, and that the organotropic action was low. He spoke highly of the value of atoxyl.

When atoxyl came to be extensively used on man it was soon found that the drug had a peculiar organotropic action in some cases, which completely contraindicated the use of the drug altogether. It had an organotropic action for the optic nerve and in some cases caused optic atrophy and complete blindness.

Further experiments on other compounds of arsenic and benzene led to the discovery by Ehrlich and his co-worker, Berthelm, of salvarsan; it was found to have a high parasitotropic action in the body and a very low organotropic action. Salvarsan had no organotropic action on the optic nerves. A peculiarity of salvarsan is that the parasitotropic action on spirochaetes is much greater in the body than *in vitro*.

Salvarsan at the time of its introduction was the drug which, of all remedies known, gave the highest parasitotropic action for spirochaetes combined with the minimum organotropic action.

The introduction of this valuable remedy marked an epoch in the treatment of syphilis, and it was found that no other known drug compared in efficacy with salvarsan and its derivatives.

Salvarsan is a powder of a pale yellow colour. It contains arsenic in amount equal to 34 per cent. expressed as the metal arsenicum, or 44.9 per cent. expressed as arsenious oxide (As_2O_3).

It is soluble in water (1 in 5), forming an acid solution. It is soluble in methyl alcohol (1 in 3), and in ethyl alcohol (1 in 12). It is also soluble in glycerine. If salvarsan is dissolved in water and caustic soda solution

is cautiously added a precipitate forms, which redissolves on the addition of slight excess of the alkali.

Salvarsan is very unstable and decomposes on exposure to the atmosphere. It is sold in hermetically sealed glass tubes, which contain an inert gas in addition to the powder. In aqueous solution salvarsan rapidly decomposes.

Chemical Tests.

1. An aqueous solution of salvarsan, when treated with a stream of H_2S gas, yields no precipitate of arsenic sulphide even after the addition of hydrochloric acid and warming. This shows the absence of inorganic arsenic.

2. An aqueous solution of salvarsan gives with either ferric chloride solution or with bromine water a brown colour, becoming a deep crimson in a few seconds.

3. Ignite the solid substance in a test tube: the substance melts and chars, whitish fumes are given off, and a blackish sublimate forms on the tube. When cool the contents of the tube have an aromatic smell, like that of nitrobenzene.

4. An aqueous solution of salvarsan is placed in a test tube, which is cooled in ice. Some solution of nitrous acid is added till present in slight excess and the mixture left for twenty minutes. The excess of nitrous acid is removed by the addition of urea solution. The solution is divided into two parts:

(a) To one part an alcoholic solution of alpha-naphthylamine is added; a beautiful violet colour results.

(b) To the other part an alcoholic solution of beta-naphthylamine is added. No vermilion colour is produced, showing the absence of atoxyl.

5. *Reinsch Test.*—Salvarsan if submitted to this test gives a definite reaction for arsenic. The fact that the arsenic is present in organic combination does not prevent the detection of arsenic by this test.

6. *Marsh-Berzelius Test.*—Salvarsan gives an unsatisfactory result, since the organic combination of the arsenic prevents its detection by this test.

In order that the Marsh-Berzelius test may be accurately employed, it is necessary for the organic compound to be broken up. This can be done by oxidation in the usual manner with nitric and sulphuric acid, or by means of hydrochloric acid and potassium chlorate. In this way the arsenic is converted to arsenic acid. The oxidized solution should be reduced by treatment with potassium meta-bisulphite and dilute sulphuric acid and the excess of sulphur dioxide boiled off.

This solution now contains the arsenic in the form of arsenious acid, which can readily be detected or estimated by the Marsh-Berzelius test.

7. *Mirror Test.*—For quantitative estimations of minute amounts of salvarsan the mirror yielded by a given quantity of salvarsan, or an organ containing it, is compared with a series of standard mirrors obtained from known amounts of arsenious oxide.

The electrolytic method of the Marsh-Berzelius test is much the most satisfactory for toxicological work.

Physiological Tests.

Animals on which these may be conveniently employed are white mice, white rats, and rabbits.

A solution of salvarsan in normal saline is taken, and a solution of caustic soda is added until the precipitate which forms just redissolves. This solution is made up to a strength of 1 per cent. (1 gram in 100 c.cm.) It is slightly alkaline in reaction, and is used for injection into animals.

Mice.—These animals are susceptible to the toxic action of salvarsan.

The maximum dose borne without a fatal result is for a mouse weighing 20 grams, about 0.004 gram—that is, 0.2 gram per kilo. Of the 1 per cent. solution, 0.4 c.cm. is injected subcutaneously under the skin of the back, and by gentle massage with a glass rod the liquid is dispersed. No fatal result should follow the injection, but larger doses will probably cause death. Smaller doses—for example, 0.3 c.cm. and 0.2 c.cm.—should also be given. They should not produce a fatal result.

Rats.—These animals are very convenient for the application of toxicological tests, since they are less delicate than mice as regards susceptibility to shock, and

they are able to withstand larger doses per kilogram body weight.

For rats a curative dose in experimental spirochaete infections is 0.05 gram of salvarsan per kilogram body weight. In a rat weighing 100 grams a dose of salvarsan of 0.5 c.cm. of 1 per cent. solution—that is, 0.005 gram—causes no toxic symptoms. The solution is given subcutaneously as above.

In a rat weighing 100 grams a dose of salvarsan of 1.5 c.cm. of 1 per cent. solution—that is, 0.015 gram—is well borne and produces no toxic symptoms. (Dose = 0.15 gram per kilo.)

In a rat weighing 100 grams a dose of salvarsan of 3 c.cm.—that is, 0.03 gram—is borne without marked toxic symptoms. (Dose = 0.3 gram per kilo.)

In the above experiments local sloughs may occur at the site of injection after a few days. These usually heal up.

Rabbits.—Doses of salvarsan of 0.2 gram per kilogram body weight are borne without toxic effect if given subcutaneously, though subsequent local sloughing is likely to occur. A dose of 0.1 gram per kilogram body weight is well borne if given intravenously.

NEO-SALVARSAN.

This is a powder of a somewhat deeper yellow colour than salvarsan; it is less finely divided, and does not adhere to the sides of the capsule in which it is contained. It is more unstable than salvarsan, and its solution quickly decomposes, especially if heated.

Solutions of neo-salvarsan should be made in distilled water or in a weak saline solution (0.4 per cent.) and the temperature of the solution should not exceed 20° to 22° C.

Neo-salvarsan forms a neutral solution, and alkali should not be added to it before use.

Neo-salvarsan is salvarsan acid sodium formaldehyde sulphoxylate. It has the formula:

Owing to the addition of the further chemical group in salvarsan, neo-salvarsan contains a lower percentage of arsenic. A dose of salvarsan must be multiplied by $\frac{2}{3}$ in order to get the corresponding dose of neo-salvarsan.

Thus 0.6 gram of salvarsan corresponds to 0.9 gram of neo-salvarsan.

Neo-salvarsan has the same physiological and therapeutic effects as salvarsan. The addition of the further chemical group to salvarsan considerably adds to the convenience and facility of administration without altering the therapeutic action of the new compound.

MODE OF ADMINISTRATION OF SALVARSAN AND NEO-SALVARSAN.

Subcutaneous and also intramuscular injections of solutions of these compounds were used, but a long experience has shown that intravenous injections are far preferable. They are more efficacious and attended with less risk if carefully given. There is much less pain and discomfort with intravenous than with the other modes of injection.

Subcutaneous and intramuscular injections are always associated with a good deal of local discomfort or pain, and in the experience of one of us (W. H. W.) local necrosis of the tissues at the site of injection is by no means uncommon. Also local inflammatory troubles may follow a subcutaneous or intramuscular injection; thus, one case in which an injection of salvarsan was given in the subscapular region developed a local pleurisy, with effusion at the site of the injection. This case was seen by one of us (W. H. W.).

Suspensions of salvarsan or neo-salvarsan in oily liquids have been recommended, but the absorption of the drugs in this mode of administration is uncertain and local troubles may follow, so that this method is certainly less desirable than the intravenous mode of administration.

PREPARATION OF SOLUTIONS.

For Intravenous Injections.

Salvarsan.—Salvarsan 0.6 gram is placed in a sterile glass flask containing 40 c.cm. of 0.5 per cent. sterile saline solution. The powder quickly dissolves on shaking. Some solution of pure caustic soda (15 per cent.) is added cautiously drop by drop until the precipitate which forms just redissolves. About 20 to 23 minims of the solution will be required. The liquid is now made up to 300 c.cm. with 0.5 per cent. saline solution. This solution is used for injection into a vein, the usual precautions being taken to prevent entry of air or escape of the arsenical solution into the subcutaneous tissue round the vein.

Neo-salvarsan.—Neo salvarsan 0.9 gram is placed in a sterile flask, and 150 c.cm. of specially pure sterile normal saline (0.4 per cent.), of temperature not exceeding 22 °C., are added. The neo-salvarsan readily dissolves, and the solution is ready for injection with the usual precautions.

For Intramuscular or Subcutaneous Injections.

Salvarsan 0.6 gram is triturated in a sterile mortar with 20 minims of a 15 per cent. caustic soda solution, 15 c.cm. of sterile distilled water are added, and one or two drops more of the caustic soda solution, if the liquid is not quite clear.

Neo-salvarsan 0.9 gram is dissolved in 18 c.cm. of sterile distilled water.

Precautions should be taken as to the purity of the distilled water used in the preparation of the saline solution and for dissolving the salvarsan or neo-salvarsan. The water should be freshly distilled and kept under perfectly aseptic conditions until required. It has been shown that if distilled water contains bacteria, the sterilization of it, while killing the bacteria, does not destroy the toxins present in them, and such water may cause a rise of temperature on intravenous injection quite apart from any toxic action of the salvarsan or neo-salvarsan.¹

SYMPTOMS FOLLOWING AN INTRAVENOUS INJECTION OF SALVARSAN OR NEO-SALVARSAN.

Slight Symptoms.

The patient should be resting in bed during the injection and for twenty-four hours afterwards. With this precaution in a number of cases no symptoms of any kind occur.

It is common, however, for slight symptoms to occur, although every care may have been taken in the preparation and administration of the solution. Thus, nausea for a few hours after the injection and occasionally vomiting are common. A rise of temperature of one or two degrees Fahrenheit, within a few hours of the injection is common. Slight headache often occurs, but this in most cases is probably the result of the rise of temperature. A slight diarrhoea—for example, two or three actions of the bowels within twenty-four hours of the injection—is not uncommon.

The above symptoms are all that occur in the great majority of cases.

Slight albuminuria for one or two days after an injection has occurred on rare occasions.

Thrombosis in the course of the vein into which the injection has been given is of rare occurrence, but has been seen by one of us (W. H. W.).

Marked pyrexia occasionally follows an injection—for example, a rise of three or four degrees Fahrenheit or even more. This may last for a few days without other marked symptoms. It has been suggested that this rise of temperature is due to the endotoxins liberated by the destructive action of the salvarsan on the spirochaetes in the body.

Shock during, or immediately after, an injection has occurred, but is very uncommon. In a recent case a fatal result occurred during the course of an injection, although every care had been taken.

Severe Symptoms.

These are of two types:

I. Symptoms of Arsenical Poisoning.

Very occasionally symptoms of acute arsenical poisoning follow an injection of salvarsan. Thus some shivering or a rigor may follow an injection; there will be a rise of temperature; headache and some pains in the limbs,

nausea and vomiting, with furred tongue and diarrhoea, may occur. The conjunctivae are injected, and in some cases subconjunctival haemorrhages occur. An erythematous rash and slight jaundice occur in these cases. The patient becomes somewhat delirious, and stupor may supervene. The urine contains albumin and some granular casts, and traces of bile are present in cases with jaundice.

II. Symptoms of Profound Toxaemia.

This is the type of case which is usually attended with a fatal result.

Details of the symptoms are given in some of the cases enumerated below. Within three days of the injection of salvarsan dangerous nervous symptoms supervene—for example, collapse and abnormal mental condition. In one case acute pain in the abdomen and pain at the back of the neck were complained of. The patient becomes stuporose with twitchings of the muscles, and epileptiform convulsions are likely to occur. Coma intervenes, with collapse and death. The pupils are often dilated and the reflexes absent. The prognosis is very grave in cases of this type. The urine is usually markedly diminished in quantity and contains albumin and casts.

The pathology of cases of this kind is difficult to understand. After careful consideration it appears that the symptoms are really due to a profound autointoxication, such as occurs in uraemia. This view is borne out by the occurrence of degenerative changes in the liver, heart, and kidneys which are found on *post-mortem* examination in these cases.

The symptoms are not to be explained by anaphylaxis due to the setting free of endotoxins consequent on the destruction of spirochaetes, since the latent period (three days or more) in some of the cases is quite incompatible with this explanation.

Most of the deaths from salvarsan or neo-salvarsan are of this type, and it is important that every safeguard should be taken to avoid catastrophes of this nature.

Post-mortem Signs in Cases of Death after Salvarsan.

There is little of a definite nature to be found in these cases beyond degenerative changes of a fatty nature, or cloudy swelling, in the heart, liver, and kidneys. In some cases death has been due to a local lesion—for example, haemorrhage from a cerebral vessel.

EXCRETION OF SALVARSAN AND TOXICOLOGICAL ANALYSES.

After an injection of salvarsan arsenic is found in the blood. Thus, one hour after the injection of 0.6 gram there was found respectively in two cases $\frac{1}{2}$ mg. and $\frac{3}{4}$ mg. of arsenic (calculated as As_2O_3) in 100 c.cm. of blood serum. The blood clot was found to be almost free of arsenic, this being found only in the blood serum.

Salvarsan is excreted mainly by the kidney and bowel. Arsenic is present in the urine and faeces for at least three weeks after an intravenous injection.

In cases of death after salvarsan arsenic is found in the abdominal viscera—for example, spleen, kidney, liver, suprarenal glands, etc. It is also found in small amounts in the muscles and blood.

A most interesting feature is that arsenic seems to be almost entirely absent from the brain and nervous system, so that the symptoms of profound toxaemia in cases of salvarsan poisoning are certainly not due to the action of the arsenic as such on the central nervous system.

SALVARSAN IN LACTATION.

To investigate the influence of salvarsan on the milk of a lactating woman to whom the drug has been administered, the milk from a woman to whom two intravenous injections of salvarsan were given was collected. The first specimen was taken 72 hours after the first injection (0.4 gram) had been given; the second specimen was collected 12 hours after the second injection, of 0.5 gram. Both of these specimens were found to be free from arsenic.

In a second woman to whom 0.5 gram of salvarsan had been given, samples of milk were collected 5½ hours, 10½ hours, 16 hours, 36 hours and 60 hours respectively after the injection. Arsenic was entirely absent from all these samples, though the most delicate tests were employed.

It thus appears certain that the benefits resulting in a

syphilitic baby who is suckling from an infected mother, to whom salvarsan is given, cannot be due to the presence of salvarsan in the milk ingested by the baby. Any improvement in the child's health in such a case is to be explained on other grounds—for example, the presence of antibodies in the mother's milk, consequent on the destruction of spirochaetes in her body as a result of her injection of salvarsan.

PRECAUTIONS IN THE ADMINISTRATION OF SALVARSAN.

It must be remembered that salvarsan and neo-salvarsan are compounds having a powerful therapeutic action, and that in some patients, in spite of all precautions that may be taken, certain toxic symptoms will develop.

The susceptibility to salvarsan of patients with sound bodily organs and in good health undoubtedly varies very much, and in a susceptible person an average dose of salvarsan may produce alarming and even dangerous symptoms. Fortunately this idiosyncrasy to the effects of salvarsan is not common in healthy people.

CONTRAINDICATIONS.

Renal Disease.

Renal disease is a contraindication to the use of salvarsan. A careful clinical examination for symptoms of the condition should be made, and also a careful examination of the urine should be carried out. It is important to note the daily quantity of urine excreted, the specific gravity, the percentage and daily quantity of urea and chlorides, and especially the presence of albumin or casts. Renal inadequacy as shown by a low figure for urea and chlorides adds to the risk of toxic symptoms from salvarsan. The presence of albumin and casts in the urine will usually be a contraindication for the administration of salvarsan. The important question to be considered is the excretory efficiency of the kidney, and if this is poor, then, generally speaking, salvarsan should be avoided if possible.

In cases of albuminuria due to pyelitis or cystitis salvarsan may be given, provided that the renal excretion is good. The same view holds also with cases of functional or physiological albuminuria. There is undoubtedly risk in giving salvarsan in cases of acute and subacute nephritis, and also in parenchymatous and chronic interstitial nephritis.

In cases of albuminuria due to nephritis of syphilitic origin very careful consideration is necessary before salvarsan should be given. There is bound to be some risk, but the call for an efficient remedy to deal with an obstinate condition of this kind may be so great as to more than counterbalance the risk. It is always wise in these conditions to give a small dose of salvarsan—for example, 0.3 gram for an adult. This dose may be repeated in four weeks, and it may be increased if the first dose was well borne.

Circulatory System.

Where there is advanced heart disease and failure of compensation, salvarsan is contraindicated. The presence of a valvular lesion, provided that compensation is well maintained and the condition of the patient good, is not necessarily a contraindication.

In advanced degenerative conditions of the heart muscle there is risk of syncope from shock, and salvarsan should be avoided. In conditions of advanced arterio-sclerosis it is wise to avoid the use of the drug.

Respiratory System.

Serious bronchial conditions—for example, septic forms of severe bronchitis—are contraindications.

Nervous System.

Salvarsan is usually contraindicated in advanced degenerative conditions of the central nervous system. In meningitis of syphilitic origin the drug should be used with great caution, and should never be given in more than half doses.

Salvarsan has been used recently in the treatment of tabes and general paralysis of the insane. As a rule, the intravenous administration of the remedy does not directly do good except in early cases. The reason for this is that when salvarsan is administered intravenously the drug is not excreted by the choroid plexus and does not penetrate to the cerebro-spinal fluid, which remains free from arsenic.²

In order to overcome this difficulty, cases of tabes and general paralysis of the insane have been treated by giving salvarsan intravenously, afterwards withdrawing blood from a vein—for example:

- (1) At an interval of an hour or so; or
- (2) After an interval of a few days.

The serum is separated under aseptic conditions, and is injected into the spinal canal by lumbar puncture. In the former case (1) the serum will contain a small amount of salvarsan. In the latter case (2) the serum will contain perhaps a trace of salvarsan, but also antibodies.

Both methods have been attended with much greater success than the mere intravenous administration of salvarsan.

It is difficult to say whether the benefit from spinal injection of salvarsanized serum is due to direct action of salvarsan in the serum on the affected nervous tissues or to the action of the antibodies present. Probably both have an important beneficial action.

In cases in middle or advanced life, where there is a certain amount of arterio-sclerosis present and the blood gives a positive Wassermann reaction, the question often arises whether salvarsan should be administered. In cases of this kind it is well to avoid the use of the drug unless there is definite and unmistakable evidence of an active syphilitic lesion.

The presence of a positive Wassermann reaction, apart from any active syphilitic lesion, is not, in our opinion, a sufficient justification for the use of salvarsan in these cases.

The presence of any serious disease of any kind should always call for the greatest consideration before a full dose of salvarsan is given. It must be remembered that there is bound to be risk of the development of serious toxic symptoms.

INTERVALS BETWEEN SUCCESSIVE DOSES.

Toxicological analyses show that a full dose of salvarsan (0.6 gram) is not completely excreted after three weeks. Probably by this time only minute traces remain in the body.

We are strongly of opinion that an interval of four weeks should elapse between the administration of full doses of salvarsan. With shorter intervals there is risk of a cumulative action, since the second dose may be given while some of the former dose still remains in the abdominal viscera.

TREATMENT OF SALVARSAN TOXAEMIA.

Prophylactic treatment is most important.

An aperient should be given the night before the remedy is administered. Alcohol and tobacco should be avoided for twenty-four hours before and after the administration. The patient should remain in bed on the day in which the drug is given, and for twenty-four hours afterwards.

Slight symptoms—such as nausea, slight pyrexia, headache, etc.—call for nothing but the simplest remedies. Should the temperature remain above normal for more than a few hours, the patient should remain in bed until it has reached the normal line and remained there for twenty-four hours.

It is wise to diet patients carefully until all symptoms have cleared up. The diet should be light—for example, milk, milk puddings, fruit, vegetables, toast, bread, etc. Meat, meat extracts, soups, and alcohol should be avoided. Constipation should be avoided by giving suitable aperients.

Where serious symptoms occur—such as collapse, twitchings, stupor or delirium or coma—an intravenous injection of normal saline (2 to 3 pints) should be given, and repeated if necessary. Normal saline may also be given subcutaneously with advantage. Rectal injections of normal saline, containing 3 drachms of sodium bicarbonate to the pint, should be given every eight hours. Where the blood pressure is not low venesection should be done, and about 10 oz. of blood withdrawn. This should be followed by the giving of saline into the vein.

If the patient becomes comatose, it is important to continue nourishment by the mouth—for example, 15 oz. of peptonized or citrated milk should be given by a stomach or nasal tube every six hours. For collapse,

strychnine (gr. $\frac{1}{6}$) may be given hypodermically every four hours, and oxygen, or oxygen passed through alcohol, may be administered with advantage.

In the early onset of toxic symptoms the following mixture should be given:

Sodium citrate
Sodium bicarbonate
Potass. citrate
Caffeine citrate
Syr. aurant.
Aq.

Every three hours.

TOXICOLOGICAL ANALYSES AND CASES.

I. Analyses of Urine and Faeces.

CASE I.—P. L. June 2nd, 1911, 0.6 gram salvarsan given.

II. Analysis of Milk.

CASE I.—This was kindly sent by Dr. McIntosh and Dr. Fildes, of the London Hospital. The mother was suffering from ulceration of the throat and a macular rash of two months' duration. Her child, aged 5 months, had a rash on the body and well marked enlargement of the spleen. On March 13th, 1911, the mother received 0.4 gram salvarsan intravenously, on March 16th 0.5 gram salvarsan intravenously, and on March 21st 0.6 gram salvarsan intramuscularly. The child was suckled all the time.

All symptoms of syphilis in the mother and child rapidly cleared up within five days of the second injection.

Analysis of samples of milk from the mother taken

- (a) Seventy-two hours after the first injection,
(b) Twelve hours after the second injection,

showed in the first case (a) the merest trace of arsenic—0.006 mg. of As₂O₃ per 100 c.cm. milk. In (b) no trace of arsenic was present.

CASE II.—B. A mother suffering from syphilis received on March 8th, 1912, 0.5 gram salvarsan given intravenously, on March 27th 0.6 gram, and on April 17th 0.6 gram.

Samples of milk were collected: (a) Five and a half hours, (b) ten and a half hours, (c) sixteen hours, (d) forty hours, and

(c) eighty-eight hours after the first injection. All of these samples were entirely free from arsenic.

III. Analyses of Blood.

CASE I.—"S." kindly sent by Dr. A. Fleming, May, 1914; 0.6 gram salvarsan given intravenously. Blood taken one hour after injection. On analysis 0.33 mg. of arsenic (As₂O₃) were found in 100 grams of blood.

CASE II.—"B." kindly sent by Dr. A. Fleming; 0.6 gram salvarsan given intravenously July 1st, 1914. Blood drawn off one hour after injection. The serum was separated from the clot. In 100 c.cm. of serum 0.5 mg. of arsenic (As₂O₃) were found. The clot contained no arsenic.

IV. Cases in which Death occurred after the Administration of Salvarsan or Neo-salvarsan.

CASE I.—A. E., aged 12. Case of congenital syphilis with ascites and cirrhosis of liver. Salvarsan was given, 0.3 gram on September 1st, 1911, and 0.3 gram on September 8th, 1911. The patient died on September 16th, 1911. Death was not accelerated by the administration of the salvarsan, since this was given as a last resort, the condition of the patient being hopeless before its administration. The liver contained arsenic corresponding to 2.5 mg. per 100 grams.

CASE II.—A female, aged 23, suffering from secondary syphilis. Given 0.4 gram salvarsan on November 30th, 1911, and 0.4 gram on December 4th, 1911.

A rise of temperature occurred after the first injection, and also after the second. On December 7th epileptiform convulsions occurred, and coma supervened. The urine contained much albumin, death occurring on the same day after a few hours.

Post-mortem examination showed fatty degeneration of the heart muscle, and cloudy swelling, with focal necrosis of the liver. Analysis showed that the liver contained arsenic in amount corresponding to 0.83 mg. per 100 grams.

CASE III.—A patient suffering from symptoms of syphilitic meningitis. On admission to hospital on August 28th, 1912, he was stuporose. He complained of headache and pain at the back of the neck. Vomiting occurred. There was ptosis of the right eyelid, and weakness of the right side of the face. Both plantar reflexes were extensor. The Wassermann reaction of the blood was positive; that of the cerebro-spinal fluid negative. On August 30th 0.5 gram of salvarsan was given intravenously. Collapse occurred four hours after, and death twenty-nine hours later.

Post-mortem examination showed that death was due to haemorrhage from a small aneurysm of the basilar artery. Analysis showed that in the liver arsenic was present in amounts corresponding to 4 mg. per 100 grams; in the brain only a mere trace was present—0.01 mg. per 100 grams.

CASE IV.—G. Tertiary syphilis. In January, 1913, 0.4 gram of salvarsan was given intravenously; there was some collapse a few hours after, but the patient recovered quickly, and was well in twenty-four hours. On July 26th, 1913, 0.4 gram of salvarsan was given intravenously; the patient was quite well after twenty-four hours, but on July 30th, 1913, the patient was seized with acute abdominal pain and pain at the back of the neck at 10 a.m. At 12.30 p.m. he was comatose and collapsed; at 5.45 p.m. he was in the same condition, with some oedema of legs. Death occurred at 9 p.m.

Apost-mortem examination was made by Dr. Salusbury Trevor, and the case was regarded as one of salvarsan poisoning.

CASE V.—Tertiary syphilis with gummata of legs. 0.6 gram salvarsan given on May 9th, 1914, caused no toxic symptoms. On May 23rd 0.6 gram salvarsan given; a rise of temperature and shivering occurred in the evening. On May 25th aphasia occurred, and later coma supervened, with convulsions and death at 10 p.m.

Post-mortem examination by Dr. Spilsbury showed some thickening of pia mater and arachnoid membrane in the brain. The heart showed very advanced fatty degeneration. A small gumma was present in the lower lobe of the left lung. The liver showed advanced fatty degeneration of the cells in the centre of the lobules. The kidneys were enlarged and showed cloudy swelling.

Analysis showed:

Liver:	1.1 milligrams of arsenic as As ₂ O ₃ per 100 grams.
Kidney:	0.2 milligram of arsenic per 100 grams.
Spleen:	2 milligrams of arsenic per 100 grams.
Brain:	No arsenic present.
Spinal Cord:	No arsenic present.
Stomach Contents:	0.08 milligram of arsenic (As ₂ O ₃) per 100 c.cm.
Aorta:	0.025 milligram of arsenic per 100 grams.

CASE VI.—M. H., aged 19 (London Hospital case).

On January 3rd, 1913, salvarsan 0.6 gram was given. On January 9th the patient vomited and became comatose; death occurred on January 12th.

Analysis showed:

		Milligrams of Arsenic (As ₂ O ₃) per 100 grams.	
Small intestine	0.1
Large intestine	0.11
Liver	0.16
Kidney	0.13
Spleen	0.17
Spinal cord	? Trace.

CASE VII.—Specimens kindly sent by Dr. McIntosh and Dr. Fildes. The patient had suffered from acute meningo-

encephalitis of syphilitic origin. On May 26th, 1913, epileptiform convulsions and coma occurred. May 29th, 0.9 gram of neo-salvarsan was given. Collapse occurred three and a half hours later, and death in four and a half hours.

Analysis showed:

	Milligrams of Arsenic per 100 grams.
Liver	0.8
Kidney	1.0
Bone	0.07
Muscle	0.06
Blood	0.05
Brain	0.02

CASE VIII.—Dog, weight 24 lb. 3 oz. Neo-salvarsan 0.3 gram was given, and the animal killed twenty-four hours later. Specimens kindly sent by Dr. McIntosh and Dr. Fildes. Arsenic (As_2O_3) was found in the organs as follows:

	Milligrams of Arsenic per 100 grams.
Liver	1.0
Kidney	0.4
Muscle	0.08
Blood	0.1
Brain	Trace only
Bone	Trace only

CASE IX.—Specimens kindly sent by Dr. McIntosh and Dr. Fildes. The patient was admitted to hospital suffering from secondary syphilis and acute nephritis on May 27th, 1913. On June 20th 0.9 gram neo-salvarsan was given; no ill effects followed. On June 27th 0.9 gram neo-salvarsan was given. On June 29th there was severe headache; on June 30th restlessness and drowsiness; on July 1st convulsion, coma, and death.

Analysis showed the presence of arsenic in the organs as follows:

	Milligrams of Arsenic per 100 grams.
Liver	0.2
Kidney	1.55
Muscle	0.03
Blood	0.02
Brain	Trace only
Bone	Trace only
Suprarenal gland	? Trace
Skin	Nil
Aorta	Nil

It is interesting to note that in this case, in which acute nephritis was present, a very high relative percentage of arsenic was found in the kidney.

CASE X.—Specimens kindly sent by Dr. McIntosh and Dr. Fildes. An infant, aged 3 weeks, suffering from severe symptoms; there was a marked nummular eruption on the arms and legs, and pemphigus was present on the hands and feet. There was ulceration and discharge from the nose. On March 28th, 1911, salvarsan 0.02 gram was given; on March 30th 0.04 gram; and on March 31st 0.04 gram, on each occasion intravenously. Death occurred on April 1st, 1911.

Analysis showed the presence of arsenic in the organs as follows:

	Milligrams of Arsenic (As_2O_3) per 100 grams.
Liver	0.4
Kidneys	0.49
Spleen	0.39
Suprarenal gland	0.17
Lung	0.03
Brain	Absent

For kindly co-operation and help in the work detailed in this paper we are greatly indebted to Dr. J. McIntosh and Dr. Paul Fildes, of the London Hospital; to Dr. B. H. Spilsbury, of St. Mary's Hospital; and to Dr. A. Fleming, of St. Mary's Hospital, London.

A CASE OF GAS GANGRENE EXHIBITING UNUSUAL PROOFS OF A BLOOD INFECTION.

BY

G. T. MULLALLY, AND J. W. McNEE,
F.R.C.S. Eng., CAPTAINS R.A.M.C., M.D.

(From a Casualty Clearing Station and a Mobile Laboratory, France.)

This case is reported because it presented, in an unusual and convincing way, proofs of the occurrence of a blood infection with gas-forming organisms. No similar case has occurred in our considerable experience of gas gangrene, nor have we heard of any other like it. The essential facts may be given at once:

Private —, Argyll and Sutherland Highlanders, was wounded late at night on March 18th, 1915, by a bullet which entered the right arm, fracturing the humerus. Gas gangrene developed in this wound on March 21st—that is, two and a half days after the injury. As the man passed through a field ambulance on March 19th he received the usual antitetanic injection below the left nipple, and was thereafter evacuated at once to a casualty clearing station. On March 20th he complained of pain at the site of the serum inoculation, and by March 21st a definite patch of gas gangrene had appeared there. On March 20th, the day after admission to the casualty clearing station, a hypodermic injection of pituitrin was made into the left forearm to combat collapse. By March 22nd the site of this puncture showed also an area of gas gangrene.

From these three places (right arm, left pectoral region, and left forearm) and also from the blood the same type of gas-forming organism was isolated by cultures made on March 22nd. This organism was of the "malignant oedema" type, most of the bacilli showing central spores.

The arm was amputated on March 24th, and the man made a good recovery, being evacuated to the base on March 27th. Subsequently information was received that he made good progress for some time, but later developed "pneumonia," from which he died on April 17th, a month after the original wound.

A brief account of the clinical features and the bacteriological findings are given below, in detail, to complete the record of the case.

The important facts in this case seem to be:

1. The rapid appearance of gas gangrene at three distant sites in the body. It is evident that the slight local injuries caused by the antitetanic injection at the field ambulance and the hypodermic injection of pituitrin at the casualty clearing station, offered suitable foci for organisms circulating in the blood stream to come to rest and develop.

2. Bacteriological evidence was obtained of what had been proved to us in nature—namely, that the gas-forming organisms had invaded the blood stream.

3. The fact that the man recovered from this severe infection sufficiently to be transferred to the base three days after the arm was amputated is in itself remarkable.

Private —, Argyll and Sutherland Highlanders, was wounded in the right arm on March 18th, 1915, and admitted to a casualty clearing station next day. When admitted he was in a state of profound collapse and almost pulseless. The bullet had entered the back of the right upper arm, and emerged in front and to the inner side, making a large ragged wound. The humerus was fractured, and the brachial artery torn across. Antitetanic serum had been injected at a field ambulance before admission. On the following day he was rather better, and the wound was thoroughly syringed out with peroxide solution. Towards evening he collapsed again and became almost pulseless. The wound was dressed, and at this time showed no definite evidence of gas gangrene. Although somewhat delirious, he now began to complain of pain in the left pectoral region, where the antitetanic injection had been given. Next morning a little crackling was felt over this area, but this was at first put down to air having, perhaps, been injected along with the serum. Owing to the collapse, he was given during the night a hypodermic injection of pituitrin into the left forearm. On March 21st his general condition was unchanged, but a large patch of gas gangrene was now evident on the inner side of the right arm and forearm, below the exit wound. Another patch of gangrene was also found on the left side of the chest, including the area of the antitetanic injection. Both gangrenous areas were freely incised and dressed with peroxide solution. The affected area on the chest wall

MAJOR W. L. KELLER, Medical Corps, U.S.A., has, we learn from the *Military Surgeon* for February, sent to the Surgeon-General of the United States Army a communication in which he says that he treated many varieties of sciatica during the past year, and has found no treatment so useful as the injection of novocain into the sacral canal through the hiatus sacralis; 4 c.cm. of a 5 per cent. solution was dissolved in 100 c.cm. of normal salt solution and sterilized by boiling. The patient was placed in the knee-chest position, and the region of the sacrum and coccyx rendered sterile by iodine. A needle from 6 to 10 cm. long, attached to a large glass syringe, was used to inject from 60 to 120 c.cm. of the solution. One injection gave absolute relief in the majority of cases, but three or four might be required. The effect was immediate, and the patient could usually walk without pain or limping when he left the table.

included skin and subcutaneous tissue only, the structures below the deep fascia not being invaded. On March 22nd he was not so well, and a further patch of gas gangrene had appeared on the outer side of the left forearm, where the pituitrin had been injected. This new area was incised, and treated as in the other cases. Cultures from all three wounds, and also from the blood, were made on this day (*vide infra*).

He now began to improve, in spite of a certain amount of spread of the gangrenous condition on the left chest into the axilla, which necessitated further incisions. The right arm was amputated above the wound on March 24th, after which the man made a good recovery, being strong enough to be evacuated to the base on the 27th.

The following are the details of the bacteriological examination:

Films were made from all three wounds, and stained by Gram's method. In all the films bacilli of malignant oedema type, showing central spores, were recognized, along with a variety of other organisms. Cultures were made from all three wounds and from the blood in the following media:

1. Shake culture in large tubes of glucose agar.
2. Broth cultures made partly anaërobic by placing a wad of cotton-wool, soaked in a mixture of pyrogallol acid and caustic soda, in the tube below the rubber stopper.

By both of these methods growth was readily obtained of an organism, which later showed central spores, and was morphologically identical with the bacillus of malignant oedema. The same organism was obtained in the cultures from all the wounds, and from the blood as well. As regards the blood, 5 c.cm. of which was used to inoculate the tubes, the broth culture yielded the better result. In all the glucose agar tubes inoculated there was marked production of gas, splitting up the medium.

We are indebted to Major H. Rogers, R.A.M.C., for permission to record this case.

AMPUTATIONS AT BASE HOSPITALS IN FRANCE.

By C. GORDON WATSON, C.M.G., F.R.C.S.,

LIEUT.-COLONEL R.A.M.C. (TEMP.);

O.C. No. 1 RED CROSS (DUCHESS OF WESTMINSTER'S) HOSPITAL.

From time to time letters have appeared in the medical press from surgeons at home criticizing the methods of their surgical confrères on this side the Channel, and no small share of this criticism has fallen on the flush amputation. Nevertheless, this method, after a run of eighteen months, is still the operation of choice in the class of case for which it came into use—severe sepsis threatening life. Our methods, especially in cranial and joint surgery, have varied from time to time, and the pendulum has swung to and fro between the radical and conservative, but our methods of amputation in cases of severe sepsis have throughout been governed on "coalition" lines; radical in the relief of sepsis and gangrene, conservative in saving life.

Flush Amputation as a Life-saving Device.

The flapless or flush amputation, the method of Antyllus, was revived in this war as a life-saving device, to deal with a special class of case seldom seen in civil life (emphysematous gangrene), because it was found to be the most efficient method, and not because of the ease of its performance, as some critics have suggested. In dealing with these cases, when amputation is decided on, three main points have to be kept in view:

1. To keep the patient alive during and after the operation.
2. To perform an operation which will check the spread of infective gangrene and prevent septicaemia.
3. To save as much of the limb as possible.

Gas Gangrene in Civil Practice.

In civil practice, amputations for crushed and mangled limbs are usually performed early, before the onset of serious sepsis, and can in most instances be conducted on

orthodox lines, without the prospect of re-amputation. In rare instances, however, acute spreading traumatic gangrene follows rapidly on fractures of the "run over by motor bus" variety. The infection is then usually streptococcal and anaërobic, with the formation of gas. Emphysematous gangrene, once it commences in the damaged tissues, spreads like lightning. Immediate amputation is required to save life, and any attempt to secure primary union will not only be useless but probably fatal. Anyone who has met with a case like this in civil practice must have been profoundly impressed.

Gas Gangrene in Gunshot Wounds.

"Gas gangrene" following gunshot wounds in this war, instead of being a rare occurrence, as in civil practice, is quite common. The onset and progress of the gas distension of a limb which precedes the gangrene is rapid beyond belief, unless seen.

In one case of wound of the thigh under our care, within six hours of the first signs of the onset, gas had extended up to the axilla and down to the ankle.

In another case of a wound in the region of the great trochanter, at 9 p.m. the wound (which had been freely laid open) showed no signs of gas. In under ten hours the man was dead, having suffered much agony, and the opposite thigh, which was uninjured, was blown up with gas to an enormous size.

The toxæmia is so fatal as to be unparalleled. Within a few hours of the onset of physical signs of gas, extensive gangrene may develop in the wounds, and life will hang upon the slender thread of an immediate and rapid amputation, with the minimum of shock.*

As the gas distends the fascial planes, pain becomes very severe, and the limb may swell to an enormous size, but with the onset of gangrene the pain usually disappears. The mental faculties may remain unclouded (despite profound toxæmia) on the very threshold of death.

When infection becomes general, on auscultation, gas may often be heard circulating in the heart, like the sound of a boiling kettle. This gives rise to great distress, and often to a shallow, contorted, almost tetanic facies. Extreme pallor is a marked feature of general infection. This may come on so suddenly as to raise the suspicion of internal hæmorrhage, and I have known a tourniquet applied to a thigh (where there was no wound of exit) until the diagnosis could be cleared up. A general infection is usually fatal from cardiac failure or gas embolism. After death not only the damaged limb but the entire body, including the great veins, liver, etc., may be distended with gas.

With this pitiful picture surgeons in France are only too familiar. Fortunately experience has taught that if the case is seen early the patient, if not the limb, can in most instances be saved. In the earliest stage, when the typical gas odour appears and a few bubbles can be squeezed from the wound, heroic incisions and the freest possible drainage, followed by constant lavage with sodium hypochlorite, will usually succeed; but if the case has come under observation when gas has begun to spread into the intramuscular planes beyond the site of injury and the limb has begun to swell, amputation is imperative. Any attempt to perform a complete amputation (that is, with flaps to cover the bone) must be made through uninfected tissues, which would not be possible in most instances, as the majority of these are thigh cases. Even when the conditions may appear favourable for a primary flap amputation clear of existing infection nothing will be gained by this procedure in the great majority of cases, for the following reasons.

Disadvantages of Flap Amputation.

1. There will be less chance of ultimately saving the patient's life because there will be less chance of checking the infection.
2. There will be more chance of the patient losing his life at the time from shock.
3. For the amputation to succeed it will have to be performed as high or higher in the limb than the second stage of a primary flush amputation.
4. Healing by first intention cannot be expected. (The cases must be seen on the spot to appreciate this.)
5. The risk of secondary hæmorrhage (a very grave danger in these cases) is greatly increased. Since the

* Intravenous ether anaesthesia is invaluable in these cases.

routine adoption of the flush method we have had the good fortune to lose no case from secondary haemorrhage following amputation in this hospital. The only death in this hospital from secondary haemorrhage after amputation, during the last six months, occurred in a case operated on near the front by the flap method. Secondary haemorrhage occurred during transit and again after admission to this hospital.

6. The need for re-amputation for sepsis or haemorrhage may be expected at a time when the patient is unable to stand further operation, and often when there is no more limb available for an amputation.

Advantages of Flush Amputation.

The advantages of the flush method are:

1. Rapidity with minimum shock.
2. A plain open surface for dressing, which is favourable to the subsequent control of sepsis and which prevents pocketing.
3. Great diminution in the risk of secondary haemorrhage.
4. The operation provides the best mechanical relief of gas tension by dividing all the tissues at right angles to the muscle planes.
5. It allows a temporary amputation to be performed close to the site of injury, so that a permanent amputation can be performed later (when sepsis is under control) a little above the injured area.
6. In cases associated with fracture the proximal end of the bone can be, and should be, left intact (that is, not sawn through) and projecting beyond the plane of muscle section, thus minimizing the risks of osteomyelitis and also providing a useful medium (a) for the application of pressure by means of dressing in case of haemorrhage (a practical point of great value), (b) for moving and fixing the limb, (c) for the application of extension to the skin.

The flush circular method may be modified, according to circumstances, by a single skin flap cut from the damaged area and turned back, thus saving a few inches of bone in the final result, although this flap is liable to slough owing to anaërobic or streptococcal infection.

Amputations for Conditions other than Gas Gangrene.

In my experience amputations are seldom called for at the base hospitals for other conditions. Cases of fractured femur, unless they develop gas infection or severe streptococcal infection, are so well and so thoroughly treated that most of the limbs are saved. Useless mangled limbs, even though not "gas infected," are best treated by the flush method in the first instance, because by this method (owing to the nature of the sepsis) more limb is saved in the end. A few cases of dry gangrene are met with in which an orthodox amputation can be performed at the seat of election.

In field ambulances or casualty clearing stations conditions are somewhat different, and it may be, and often is, practicable to perform amputations with flaps for severely damaged limbs before the onset of sepsis, just as in civil practice. Even under these more favourable conditions the result may be vitiated by a hurried evacuation (as occurred in the case mentioned above). These remarks refer in the main to the lower extremity. Gas infection in the arm is not only less common but also less serious.

After-Treatment of Flush Amputation.

After-treatment of the flush amputation seems to give rise to trouble at home. In many instances at this hospital the amputations have been completed by a secondary operation, and in every case with satisfactory results. Unfortunately, we have been compelled to send most of the cases home after the primary amputation.

The secondary amputation should be done as soon as sepsis is under control and the general condition of the patient is favourable to further amputation, and before extensive cicatrization has occurred.

The details of the secondary amputation are important. If flaps are cut and muscle planes opened up, a "flare up" may be expected, but if the muscle attached to the bone is carefully separated from the periosteum by snipping with scissors until the amount of bone required to be removed has been bared, and if the bone is divided without lacerating the granulation tissue, the operation can be

done without any local or general reaction. Before dividing the bone, the handle of a Lane's bone elevator should be passed over the bone and the blade held upwards by an assistant. This serves to protect the soft parts from the saw and to steady the limb. The flexible metal of the fracture box can be used to serve the same purpose. The skin can be brought together without undercutting and need not necessarily be sutured at the time, although sutures should be inserted for tying later. Deep mattress sutures should be used and rubber tubing inserted beneath the loop and knot of the stitch to avoid sloughing of the skin from pressure. This stage is greatly facilitated if a single flap has been cut and turned back in the first instance. The periosteum should not be stripped back from the bone, otherwise new bone is thrown out in the muscles. During the interval between the first and second operation the skin should be kept stretched by means of an extension attached either to a weight and pulley or to the bone stump, if long enough, or to a Thomas's knee-splint. A big metal ring (18 in. diameter) may be used for the stirrup to facilitate dressing.

When the bone is left long and projecting beyond the divided muscles, troubles in the form of necrosis and intramuscular callus should not arise, troubles which have formed the basis of some complaints in the past. Some critics seem to imagine that the operation is performed (when the bone is cut short) as a permanent procedure, and that healing by granulation is to be awaited. This involves a very prolonged convalescence, and in all probability a painful stump with indifferent skin prone to ulceration. The second operation can and should be performed before any serious cicatricial contraction has occurred. In several instances this has been done here under gas and oxygen, and a completely healed and comfortable stump has been secured within a month of the original amputation.

Consultants to Consult.

A well-known surgeon, who has retired from practice, writing in the *Lancet* (August 7th, 1915) to criticize this operation, says: "It must be remembered that our younger surgeons at the front have no experience to guide them; they are largely guided by what they have read." Every surgical base has the advantage of the advice of a consulting surgeon (contemporaries, more or less, of our critic). Practically all the surgery is done by surgeons who in civil life are on the staff of one or other of the London or provincial hospitals. These surgeons are, in fact, not guided by what they have read, but by what they have seen out here, and should be far better judges (aided by the consultants) of the fitness of any procedure than those who base their opinions of conditions in France on what they read or even on what they see at home when the danger of death has been surmounted by the procedures they call in question.

THE AFTER-TREATMENT OF AMPUTATION STUMPS.

By C. W. G. BRYAN, F.R.C.S., TEMP. CAPTAIN R.A.M.C.,

BRITISH EXPEDITIONARY FORCE.

[SURGICAL REGISTRAR, ST. MARY'S HOSPITAL, LONDON.]

In amputations performed for septic gunshot wounds it is usually necessary to leave the wound unsutured, and often a rapid operation has to be carried out with flaps insufficient to cover the end of the bone, which must be excised at a later date.

At the exhibition of fracture apparatus at the Royal Society of Medicine in October, 1915,¹ Sir George Makins showed a short Thomas's knee-splint for exerting traction on the soft parts of an amputation stump. I have been using recently a simple and easily-made arrangement which has the advantage of permitting the wound to be dressed without relaxation of the pull on the soft parts, a continual powerful extension of skin and muscles being kept up.

A ring of aluminium, having a diameter of eighteen inches, is made from a length of the splinting supplied in the regulation field fracture box. All round the amputation stump, from the joint above to about an inch from the edges of the wound, longitudinal strips of two-inch

adhesive strapping are applied; these strips are prolonged about twelve inches beyond the end of the stump and attached to the aluminium ring. The ring is then suspended by three pieces of cord, tied to it equidistant from one another, the cords passing through pulleys hooked to a

FIG. 1.—The extension apparatus applied to a stump after amputation through the upper third of the arm.

Balkan splint, to which an extra bar of wood has been bolted (Figs. 1 and 2).

The free ends of the cords are tied together and one or more weights are hooked on, at or near the point of junction, so adjusted that the tension on the three cords is approximately equal. For a thigh amputation a weight of about 8 lb. is used, and for the arm about 5 lb. suffices. For an amputation stump of the lower extremity, the foot of the bed is raised on blocks to provide counter-extension.

The wound is accessible for dressing through the open ring, the pull on the soft parts being kept up uninterruptedly.

The method is used as soon as the acute inflammation of the wound has subsided. If long flaps have been fashioned, they are pulled down by the appliance and their edges approximated. If it has not been possible to form

FIG. 2.—The extension apparatus applied to an amputation stump of the thigh.

long flaps the bone may not be covered, but the soft parts are kept from retraction until such time as a secondary removal of bone can be carried out.

When the wound is granulating and sufficiently healthy to permit of partial closure, the soft parts are dissected up from the bone, and the necessary amount of the latter is removed; in some cases the skin edges can be approximated by a few mattress sutures, free drainage being provided. The extension is then reapplied and kept up until the wound is completely healed.

If at the first operation it is possible to suture the amputation wound, it is advantageous to take the tension

off the flaps in the way here described, and for the same purpose it may be of use for amputations in civil practice.

The appliance allows the patient free movement and encourages mobility of the joint above; if necessary, the position of the Balkan splint is moved from day to day for this purpose.

I have used the aluminium ring attached to a Thomas's splint, but the method of extension by weight and pulley gives more powerful and continuous traction than a fixed extension, it allows more movement in the joint above, it adjusts itself to the patient's movements in bed, and he is more comfortable and more easily nursed.

I wish to express my thanks to Lieutenant-Colonel T. McDermott, R.A.M.C., for permission to publish this note, and to Lieutenant C. H. Hopwood, R.A.M.C., for the photographs with which my description is illustrated.

REFERENCE.

A METHOD OF TREATING GUNSHOT FRACTURES BY AN EXTERNAL FIXATION APPARATUS.

BY

B. SANGSTER SIMMONDS, M.B., B.S. LOND.,
GRAYLINGWELL WAR HOSPITAL, CHICHESTER.

THE difficulty of maintaining the bones in good position in some cases of gunshot wound, in which large septic wounds were present, led me to devise this method.

My plan is by means of an aseptic operation to insert into the bone, at a distance from the seat of fracture, screws which are long enough to project well beyond the surface of the skin, and to immobilize the fragments by means of a rigid plate fixed to the screws by nuts, the whole operation being done without interfering with the original wound.

Since I have devised this operation I find that other methods of fixation by means of an external apparatus have been used, but can find no record of such an apparatus being used for the treatment of compound fractures. Parkhill, by means of an open operation, exposed the fractured ends of the bone, placed them in correct position, inserted long screws and fixed them in position by an apparatus external to the skin, afterwards closing the wound. Lambotte has described an apparatus for the treatment of simple fractures by means of a rigid bar external to the skin attached to four long screws inserted into the bone. In this case also the bones are placed in position by means of an open operation, and I can find no statement that he has used it in septic compound fractures. Further, the apparatus also is complicated and expensive.

Experience in all recent wars up to the present has taught that in cases of septic compound fractures the wound should in no case be explored, on account of the risk of the serious spread of infection. But in the present war some surgeons have plated these fractures, leaving the wounds freely open, with excellent results. This operation, I believe, however, is not recommended by the majority of surgeons, the results in many cases being unsatisfactory.

The apparatus which I have been using is shown in FIG. 1. It consists of a plate of the form indicated made

FIG. 1.—The apparatus used in the operation.

of sheet brass $\frac{1}{8}$ in. thick and plated with tin, four screws long enough when fixed in the bone to extend about $1\frac{1}{2}$ to 2 in. beyond the skin, and a pair of nuts for each screw by means of which the plate is fixed in position. The screws I have been using consist of a wood screw thread for screwing into the bone, attached by means of a collar to

a $\frac{1}{8}$ in. steel rod in which is cut a thread for the nuts. The collar by means of which the two are joined forms a shoulder up to which the wood thread is screwed home into the bone. The distal end of the screw has a square section, to which a clock key is fitted for screwing it into the bone.

The operation is performed as follows:

The arm is shaved and the skin cleaned as far as possible the day before the operation, and the parts above and below the wound are covered with a sterile dressing and a mackintosh, to prevent as far as possible any soiling by the discharge from the wound. When the patient is under the anaesthetic the wound is covered with dressings

FIG. 2.—Arm after operation.

and a sterile bandage, the whole of which is painted with tincture of iodine. The bandages above and below the wound are then removed, the skin is well cleaned with petrol or acetone, and when quite dry is painted with iodine.

The limb is then manipulated to bring the fragments into as perfect position as possible. In the case of the humerus and radius the posterior surface of the bone is selected for operation; in the case of the tibia the subcutaneous surface.

The point for insertion of the first screw is the highest point of the shaft of the bone, paying due regard to important structures, such as the circumflex nerve. A longitudinal incision, $\frac{1}{4}$ in. long, is made over the centre of the surface of the bone at the point selected. With a blunt dissector a passage is cleared down to the bone, the compact layer of which is then drilled with a hand drill. The point of the screw is made to enter the hole, and by means of the clock key is screwed home. It is very important that no pressure whatever shall be used

FIG. 4.—Fractured tibia. Lateral view immediately after operation.

when the screw has once commenced to bite, the clock key merely being held between the finger and thumb so that the screw cuts its own way into the bone. In a similar way the second screw is inserted in the lower end of the shaft. These two screws can now be used if necessary in order to manoeuvre the fragments into more perfect position. The plate is then placed in position over these two screws and used as a guide in making the incisions for the third and fourth screws, which are inserted in the same way. Great care must be exercised in inserting the screws parallel to each other and at right angles to the surface of the bone; if this is not done accurately the screws will not pass through the slot in the plate.

The nuts are placed one on each side of the plate on each screw, and when the plate is in position are tightened with a spanner. The wounds through which the screws pass are then dressed with small pieces of gauze soaked in collodion or Whitehead's varnish.

The plate can be bent slightly to counteract any slight error in the position of the screws, but only in the first case I treated in this way was any bending necessary.

The plate used for the radius is made slightly curved to follow the curve of the bone; for other bones it is straight.

In cases of fracture of both bones of the forearm it is only necessary to correct the displacement of the radius, as when this is brought into correct position the ulna always corrects itself. I first noticed this fact by examining skiagrams of several dozens of cases of badly comminuted fractures of the shaft of the ulna in which the radius was intact. In no case was there any linear displacement of the fragments whatever. The only exception I have seen was a case in which the interosseous membrane and muscles were badly lacerated, the upper fragment of the ulna projecting through the wound.

The converse does not hold true on account of the attachment of the pronators and supinators to the radius.

FIG. 3.—The same case. Lateral view of forearm after operation. The screws were left in for nine weeks, during which time there was no rise of temperature, and no suppuration in any of the screw holes.

In the majority of the cases treated in this way there was no rise of temperature whatever following the operation. In one case of gunshot wound of the forearm, with comminuted fractures of the middle of the shafts of the radius and ulna and large septic entrance and exit wounds, the plate was left in position for nine weeks; when the screws were removed there was no sign of suppuration in any of the screw holes. In some other cases there has been some superficial suppuration in some of the screw holes, which did not, however, necessitate removal of the screws till firm union was obtained.

The great advantages of this method are: First, that the apparatus is simple and inexpensive; those I have used have been made on the premises by the engineer at Graylingwell War Hospital, Chichester, at the cost of a few shillings. Secondly, that the operation is simple and rapidly performed, the original wound is not interfered with, and healthy tissues are not extensively opened.

I have not tried this method in cases of fracture of the femur, as most of our cases have been four or five weeks

FIG. 5.—Fractured tibia. The same case, four weeks after removal of screws. Lateral view.

old when admitted. The apparatus, however, would be suitable for cases sufficiently recent to enable one to get the fragments into position by extension on the operating table. For this purpose I have had screws made sufficiently long to pass right through the femur, thus penetrating both compact layers of the bone, and so giving much greater strength to the apparatus.

With suitably shaped plates I intend to try it in cases of fractured jaw, clavicle, and other bones.

Owing to the difficulty of joining a wood screw to one with a thread for nuts the collar is somewhat clumsy, and I am now having screws made in one piece, the thread for screwing into the bone being cut with an ordinary die and at the end being ground to a point in such a way that it forms a tap to cut its way into the bone.

P.S.—Messrs. Down Bros. are now making these plates of steel in four sizes for radius, tibia, humerus and femur, and screws for these made in one piece.

THE late Surgeon-Major Frederic Carter, of Ongar, Essex, who served in the Mutiny, left estate valued at £34,343.

A NOTE ON DYSENTERIC ARTHRITIS.

BY

T. GILLMAN MOORHEAD, CAPTAIN (TEMP.) R.A.M.C.

JUDGING from the scanty literature at my disposal, the occurrence of arthritis, single or multiple, as a complication or sequel of amoebic dysentery has received very little attention, though some writers, such as Phillips, briefly refer to it, and Manson states that a condition resembling gonorrhoeal rheumatism has frequently been noted as a sequel, and that at least one epidemic has been recorded in which a large proportion of the cases became affected in this way. Osler also briefly refers to the possibility of its occurrence.

As, however, its practical importance seems to have been overlooked, I write this note with the object of pointing out that in all cases of arthritis occurring in our troops a history of dysentery should be inquired for, and, if such a history is obtained, a course of emetine should at once be ordered. In my experience of six recent cases emetine clears up the arthritis most rapidly after other treatment has failed.

In four out of the six cases there was definite proof that amoebic dysentery had been present, either by the finding of amoebae in the stools at the time the arthritis was present, or owing to the fact that the patient had been previously treated in this hospital for amoebic dysentery, and that amoebae had been found at the time of this treatment.

In two cases the history of dysentery while at the peninsula was quite definite, but I had no means of determining whether the dysentery had been of the amoebic or bacillary variety. One of these cases—a bad one—was given both serum and emetine; the other was treated by emetine alone, and both rapidly recovered.

The case that first called my attention to the subject was that of a man who was admitted on December 4th, 1915, suffering from well-marked amoebic dysentery, confirmed by examination of the motions. He was given a course of 5 grains of emetine, and rapidly improved as far as the dysentery was concerned, but remained weak and very much pulled down.

On December 29th, 1915, our bacteriologist (Lieutenant Willmore) reported the stools as containing no amoebae.

On January 7th, 1916, he complained of severe pain in the right knee, and on the next day the joint was found to be much swollen, due to the presence of fluid and general thickening of the periarticular tissues. The condition, in fact, as Manson states, exactly resembled that of gonorrhoeal rheumatism. The patient was put on large doses of sodium salicylate and alkalies, but on January 9th the right knee was worse, the left knee was also involved, and the right elbow and both wrist-joints were also painful and swollen. By January 14th there was no improvement; the patient could not move in bed owing to the pain, and the slightest attempted movement of any of the affected joints caused acute agony. On this date it was decided to stop the salicylates, and to start a course of emetine injections.

By January 18th the wrist and elbow had practically completely cleared up, and the knees, while still swollen, were enormously improved, and could be moved freely without pain. A week later there was still further improvement, and in the first week of February the patient was able to get out of bed for a short time daily.

The other cases resembled this as far as the appearance of the affected joints were concerned, except that in none of the others were the joints of the arms involved, the knees being the joints to suffer most, as they were affected in all of the cases, while in two the ankles also, and in one the right hip-joint, were involved.

The complete proof that these cases of arthritis were amoebic in origin is wanting, as I did not feel justified in aspirating the joints, but if we may rely on the therapeutic test of rapid recovery under the use of emetine, there is little doubt as to the nature of the condition.

It is possible that the severe strain put on the joints by the life of a soldier renders them unusually liable to suffer, and if there should be any extensive appearance of the condition it is important that medical officers should be on the look-out for it, and should at any rate give anti-dysenteric treatment a trial.

THE King has granted Dr. Gordon O'Neill, Professor of Obstetrics in the Peiyang Medical Council, Tientsin, permission to wear the Seventh Class of the Order of the Excellent Crop, conferred upon him by the President of the Chinese Republic.

PRELIMINARY NOTE ON A DISEASE CALLED
"BUNGPAKKA."FOUND IN THE NORTHERN TERRITORIES
OF THE GOLD COAST.

By C. R. PATTON, M.B., CH.B.,

MEDICAL OFFICER WEST AFRICAN MEDICAL SERVICE.

THIS curious disease has been known to the natives of West Africa for some time, as the Chief of Tansia told me that he had had it at the time when the slave raider Samori overran the Northern Territories about twenty years ago. It goes by many names, according to the severity of the outbreak, to the locality and tribe in which it manifests itself. The various natives of the Gold Coast, the Northern Territories, the Nigerias, and the Senegal are said to recognize it readily, and it is probably even more widely spread, but information on the subject is scanty. In the Wa district, at any rate, certain low-lying villages in the swamps seem to be more adapted to the incidence and spread of "bungpakka" than others.

Names.

The multiplicity of names will probably give one an idea of its prevalence; thus, in the following languages its synonyms are:

Hausa: *Chewan daji* (?). In Robinson's Hausa dictionary is mentioned "a fever which breaks out when the guinea-corn is ripe (*Chiewo na sabon dawa*). To prevent being attacked by it the Hausas give presents of *dawa* to the poor."

Dagarti: *Bunyura*, *Bunyuri*, *Bungura*.

Walla: *Bungyura*.

Lobi: *Bungpakka*, *Bungpwakka*, *Bungpwakka*, *Bungworra*.

Season.

It occurs both sporadically and epidemically at the time when the guinea-corn and rice (*hakki*) are ripe and ready for harvesting—that is to say, just after the rainy season in the Northern Territories.

Sex and Age.

It attacks both sexes, and it occurs at all ages in those who are able to eat grain. Adults appear to be more prone to it than children.

Etiology.

The natives regard it as infectious. Some ascribe it to the sun's activity at this time of the year. It appears to me to be due to a micro-organismal infection which produces a neuro-toxic effect as well as a local reaction. In every one of the pus slides I examined I found a heavy infection of *saccharomyces*. Every precaution was taken to prevent contamination, and yet the fields showed yeast cells in all stages of gemmation. The slides were made, fixed, and stained as soon as the pus was taken from the abscess. The cultures showed a true fungus growth. No experiments were tried owing to lack of material. Personally, I am inclined to think that the disease is caused and perpetuated by a yeast fungus; the yeast spores probably remain in the mud bins in which the grain is stored awaiting a favourable opportunity to grow, they get their chance after the rains, when the interior of the bins becomes a hot moist chamber. The grain becomes infected in the bin, the people eat the grain raw, and being usually constipated, their intestines are secondary incubators. The yeast cells are probably absorbed from the intestine somewhat in the same way as fat is by migratory leucocytes, and thence into the general circulation.

Incubation Period.

The definite incubation period appears to be three days, during which there is malaise, headache, a sense of fatigue, anorexia, intense thirst, and constipation.

Symptoms.

The onset is sudden; one or more rigors may usher in the attack. The temperature rises rapidly to 103° or so. There is extreme tenderness in the muscles which are to be the seats of inflammation. Within twelve hours painful tumours make their appearance in the affected muscles; only the voluntary muscles are affected, and the abscesses seem always to occur near their insertions. There may be only one nodule, or a crop. In some

cases the distribution is bilaterally symmetrical. The tumours are deep-seated; they are hard, non-fluctuating, very painful, with their long axes either in or parallel to the long axes of the muscles affected. They do not correspond to lymphatic glands. Each tumour is about the size of an English hen's egg. They are at first hard and firm, and are easily visible and palpable; later on, if the patient survives, they become slightly soft, but never flabby. Usually, in mild cases, the abscesses point after some weeks, and burst if unopened. As a rule, the fewer the nodules the better the prognosis.

The natives often incise the nodules to relieve the symptoms; if white fluid exudes, the case is labelled fatal; if the fluid is yellow, the patient will recover. Sometimes there is no fluid, and then the Ju-ju man gives the patient a delphic reply. Some of the natives carry the scars of former "bungpaga" abscesses.

The patient is alert and sleepless on account of the great pain in the affected muscles. Sedatives have to be used in large doses before any relief is obtained; salicylates are of no avail.

If the patient survives the acute stage he stands a good chance of recovery. The deaths usually occur within the first week, the third and sixth days seeming to be the most critical. Even during convalescence (for two months or more) the patient exhibits an occasional febrile reaction.

Mortality.

"When it is called Bungpaga it is very fatal, nearly all die; but when we call it Bungyura most of the people recover." This is the typically oracular answer one gets from the natives. Some of the people consider the disease to be as fatal as sleeping sickness.

General Remarks.

From the investigations of Drs. Corson, Ryan, and myself we are inclined to believe that this is a special disease. The Hausas say that they have seen it occur among the other tribes, but not among themselves. Perhaps they wish strangers to be impressed with the efficacy of the dawa offerings. One could not discover whether the fortunate poor contracted the disease after eating these oblations.

The natives also readily recognize such infections as actinomycosis, anthrax, bubonic plague, guinea-worm, and malaria, syphilis, etc. Their knowledge of disease seems to be exact, but they are so superstitious and suspicious that they make one wade through a quagmire of falsehood and general information to get to the tiny islets of truth bearing on one's quest.

An epidemic of this disease broke out recently among the labourers employed on the Yeji-Mcongo road. The officer in charge of the construction work said that by far the largest number of fatalities were due to this disease. He had made arrangements for the provisioning of his workmen; large quantities of maize, millet, guinea-corn, etc., were bought and stored in mud huts so as to meet requirements. Some of this grain may have been infected, and may have given rise to this outbreak. Preventive measures should be adopted in good time so as to prevent an outbreak among troops who live on such food. Millet is often eaten in the raw state. Our men should be warned of their danger and should be ordered to cook their grain.

Investigations into the cause and spread of this disease are being taken in hand in West Africa, but it would help matters considerably if all cases of this disease were reported on.

An interesting experiment in school hygiene at Winchester, Massachusetts, is described in the *Boston Medical and Surgical Journal*. Two seventh-grade classes, consisting of children of the same kind, were compared after one class had been for four months taught in a room so altered that a full supply of fresh air could be admitted. The temperature was kept at about 45° F., and the children were clothed in blanket coats and bloomers, with lined canvas boots. At the end of the period the children were compared with those of another seventh-grade class in the same building who worked in an ordinary room. It was found that whereas the average gain in weight of the open-air class was 3.61, that of the other class was 1.69. In height the open-air class gained 0.49, the other 0.24. In the haemoglobin test the open-air class gained 4.55, while the other lost 3.07 per cent.

AN OBSERVATION IN PERNICIOUS ANAEMIA.

BY

O. LEYTON, M.D., D.Sc., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

SOME years ago, after careful examination of the literature, I published a paper* embodying an original idea, and ventured to express the view that, although original, I doubted whether it was novel. A few weeks later, whilst buried in journals in search of data on quite a different subject, I found that my idea had been anticipated some years previously, and on looking up that paper I found yet an earlier reference to a journal published in 1886 embodying the treatment suggested.

The vastness of the literature must be my excuse for absence of any references to experiments of a similar nature to the one I am about to describe.

In March, 1915, I had under my care a very severe case of pernicious anaemia, also one of well-marked erythraemia (polycythaemia).

The consensus of opinion as to the process leading to anaemia in pernicious anaemia is that an excessive destruction of red cells is occurring. The cause of this destruction has been a subject of considerable work, more speculation, and no satisfaction. It would ill become me to add to the speculation.

Erythraemia must be due to one or a combination of the following: abnormally rapid development of red cells, an abnormally slow destruction of red cells, an insufficient quantity of plasma.

On an attempt to determine which of these takes the most prominent part, I am engaged at present.

It seemed to me that it would be of interest to note what would happen if I were to transfer some quantity of blood from the patient suffering from erythraemia to the patient who had pernicious anaemia, and at the same time inject into the erythraemic patient some blood from the case of pernicious anaemia.

Courtesy to my colleague, Dr. F. J. Smith, makes me digress for a moment: the case of pernicious anaemia under my care wished to return home, and therefore left the hospital, and I am indebted to Dr. F. J. Smith for transferring to me one of his patients.

The patients had the circumstances explained to them in detail; that there were certain risks, and that as far as I knew, no similar observation had been recorded. The two men said that they were quite willing to undergo any treatment which might in any way benefit them, and that they did not mind any risk, because for several years their lives had been spent in hospitals and were of no advantage to them or any one else.

Details of the method of transferring the blood are unnecessary. All that is essential is to state that the apparatus was washed out with sterile olive oil and drained, so that there should be no excess, and that coagulation was prevented by the addition of a minute quantity of sodium citrate. Every precaution was taken to prevent any air being injected, and a window quite close to the point of injection allowed me to be certain that not a bubble entered.

After a small quantity—that is to say, 2 oz.—of blood had been injected into the man suffering from pernicious anaemia, he went paler; he complained of nausea and faintness, and the injection was immediately stopped. He then became slightly flushed in the face, and made grimaces as if he were undergoing pain. On being asked, he stated that he had pain all over him, something like cramp, quite severe; this lasted for a minute, and then disappeared, and he was soon quite comfortable.

I was very disappointed that only so small a quantity of blood had been introduced, but nevertheless thought that if the blood contained some material which stimulated production of red cells this might lead to improvement in the condition of the patient. Examination of the blood a week later showed that the red cells had risen from 600,000 to 1,050,000, and the haemoglobin percentage from 10 to 20.

As the result was so promising it made me almost regret that it was not my custom to publish any observation on treatment within a year of having made it; this resolution

* A Contribution to the Treatment of Chronic Empyema. *BRITISH MEDICAL JOURNAL*, April 15th, 1905.

had been brought about by a statement of a former teacher, whom I hold in the greatest respect, who had once (probably humorously, although truthfully) made the remark that journals took so long to publish papers that he had often altered his view before his theories appeared in print.

The result was sufficiently satisfactory to make the patient anxious to have further treatment, and five weeks later I again transferred blood, and on this occasion some 8 oz. of blood. The symptoms produced were similar to those produced on the former occasion, but much more severe. The patient vomited for close upon half an hour, and for a time gave rise to some anxiety due to the strain thrown upon his heart. The after-effects were not satisfactory, neither the number of red cells nor the quantity of haemoglobin being increased to any large extent.

Therefore, in this case, at any rate, transference of blood proved to be useless. The patient left the London Hospital in March, 1916, in a condition very similar to that in which he entered it in March, 1915. I record the observation in order that other observers to whom a similar idea may occur should realize that there is a certain risk in transferring large quantities, and that it is quite probable no benefit will result.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

THE ISOLATION HOSPITAL, SOUTHAMPTON.

AN ANOMALOUS CASE OF ENTERIC FEVER.

(Reported by OSCAR HOLDEN, M.D., D.P.H., Resident
Medical Officer.)

T. F., a gardener aged 25, was admitted on August 1st, 1915. He had been out of sorts for about fourteen days, but remained up and about. Walked a considerable distance on July 29th, and got up to breakfast on July 31st, but went to bed at mid-day, and was delirious the same evening. He had consulted his private doctor on July 30th because of diarrhoea. He had not been inoculated against typhoid fever.

On admission he was seriously ill. There were sordes around the teeth and lips, the tongue was dry and foul, but there were no spots or rash. The abdomen was tympanitic, rigid, and diffusely tender; on palpation it moved fairly well on respiration. The spleen was not palpable; the liver was felt just below the chest margin. There was no cough or other lung signs, but a most persistent hicough. The heart sounds were regular and strong, with a very faint rub at the apex.

The chief points in the further progress of the case were: Violent hicough until the end; practically complete suppression of urine for forty hours after admission, and then a copious flow with incontinence; obstinate constipation for fifty-two hours after admission, and then large, frequent, and offensive stools, also incontinent. The abdomen, at first distended, became flat, but the tenderness persisted. Unconsciousness, becoming more profound, ensued, with increasing restlessness until death.

At no time was his temperature above 97° F. Widal reactions were inconclusive. Lumbar puncture, thirty-six hours before death, afforded no evidences of intraspinal mischief. The urine contained abundant albumin and a few granular casts. Death appeared to be due to a profound intoxication.

Post-mortem Examination.

August 7th, 2.30 p.m. Well-developed man. Post-mortem staining marked.

Abdomen: The omentum was spread out over the small gut and was injected. No free peritoneal fluid and no adhesions. Stomach, duodenum, and jejunum normal, except for slight injection, probably due to turpentine given therapeutically. The ileum showed no enlargement of solitary follicles or Peyer's patches, except in the last foot. Here in the upper half the patches and follicles were reddened and swollen, but not ulcerated. In the 5 in. above the ileo-caecal valve were masses of small ulcers, with some larger ones. So numerous were the ulcers that the gut wall presented a ragged, rat-eaten appearance. The ileal side of the valve was partially sloughed away. The appearance of the ulcers hardly warranted the

assumption that they were typhoidal, but bacteriologically they proved to be such. The appendix and large gut were normal. The spleen was hard, not enlarged, and rather anaemic. The liver, normal. The kidneys showed parenchymatous nephritis, more severe in the right organ. **Heart:** A patch of recent fibrinous pericarditis showed over the apex. There was no valvular disease. Atheromatous patches were scattered over the ascending aorta. The brain and meninges were normal.

Comments.

It seemed that the patient had been up and about during an attack of enteric fever, ending fatally six days after taking to bed.

The complete constipation may be accounted for by blockage at the ileo-caecal valve during separation of the sloughs; the subsequent diarrhoea to imperfect closure after sloughing. The suppression of urine may have been caused by the onset of a specific parenchymatous nephritis.

The continual subnormal temperature is difficult to account for in view of the extensive ulceration and sloughing of the lower end of the ileum. The spleen was of a non-febrile type. Possibly the intoxication was so great that there was a depression of the cerebral nerve centres, but the heart rhythm was unaffected and the strength unimpaired until a few hours before death. The action of the toxin was similar to that seen in some suddenly fatal cases of diphtheria.

I have to thank Dr. Lauder, M.O.H. Southampton, for permission to record this case.

Reports of Societies.

VISUAL DISTURBANCES FROM CEREBRAL LESIONS.

At a meeting of the Ophthalmological Section of the Royal Society of Medicine on March 22nd, Colonel LISTER, A.M.S., C.M.G., and Lieutenant-Colonel GORDON HOLMES, M.D., R.A.M.C., read a paper on disturbances of vision from cerebral lesions, with special reference to the cortical representation of the macula. The authors stated that in their work at the base hospitals in France during the past eighteen months they had observed a large number of cases in which the vision was affected by lesions of various portions of the optic system, and a certain number of suitable cases had been selected bearing on the cerebral localization of vision, more particularly on the representation of different regions of the retina in the cortex. As the observations were necessarily made at an early stage after the infliction of the injury, some of the effects observed may have been due to functional disturbances, rather than to local injuries of the corresponding cortical areas or their centripetal fibres; but if it could be shown that there was a constant relation between the probable site of the injury and the form of the visual defect, certain general conclusions would be justifiable. The injuries in the cases referred to included penetrating and perforating wounds of the cranium by rifle bullets, shell fragments, and shrapnel, as well as local concussion and depressed fractures.

Superior quadrantic hemianopia was strikingly rare in gunshot wounds of the occipital region. The fact that in over 2,000 cases of head injury a central scotoma was never seen when a direct injury of the occipital poles could be excluded was regarded as striking evidence that central vision was represented on either, or both, the mesial or the lateral surface of the posterior borders of the occipital lobes. The observations conformed to the general view that the visual area corresponds with, or at least includes, the area striata. No conclusive evidence had been obtained that achromatopsia, with intact vision for white, was produced by cerebral lesions which involved either the cortex or the optic radiations.

The authors formulated the following conclusions, which they do not yet regard as final:

1. The upper half of each retina is represented in the dorsal, and the lower in the ventral, part of each visual area.
2. The centre for macular or central vision lies in the posterior extremities of the visual areas, probably on the margins and the lateral surfaces of the occipital lobes.
3. That portion of each upper quadrant of the retina in the immediate neighbourhood of, and including, the

adjacent part of the fovea centralis is represented in the upper and posterior part of the visual area in the opposite hemisphere, and vice versa.

4. The centre for vision from the periphery of the retinae is probably situated in the anterior end of the visual area, and the serial concentric zones of the retina from the macula to the periphery are probably represented in this order from behind forwards in the visual area.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on March 3rd Dr. WALTER SMITH read a paper on *Soya bean (Glycine hispida) and its uses in physiology and medicine*. Attention was drawn to its important dietetic and economic applications, which admitted of considerable extensions, if its cultivation were extended, especially in South Africa. The seeds were free from starch and sugar, and had been utilized in the treatment of diabetes. Takeuchi, a Japanese savant, had discovered that the bean contained a specific ferment, urease, which rapidly converted urea into ammonium carbonate. The relations of ordinary urea to ammonium cyanate and of sulphur urea (thio urea) were discussed, and the mutual reversibility of the process in each case was experimentally shown. The almost immediate influence of urease in converting urea into ammonium carbonate was demonstrated, and it was pointed out that urea had recently been discovered in a number of plants up to as much as 3.5 per cent. in a fungus. A practical point in connexion with urease was its application to the quantitative estimation of urea. The most rapid methods of estimation for routine work were: (a) The hypobromite method; (b) Folin's process with $MgCl_2$ and HCl ; (c) the most accurate method was by urease, which was quite applicable to clinical work, and was, in fact, a very simple and easy method. The ammonia was absorbed by decinormal sulphuric acid.

Rebielus.

LARYNGOLOGY AND OTOTOLOGY.

DR. W. H. KELSON'S book, *Diseases of the Throat, Nose, and Ear*,¹ illustrates the extreme difficulty of presenting a useful survey of these large subjects in a small space. He states in the preface that it is "written for general practitioners and senior students, and so full details are given as regards such proceedings as the doctor himself usually undertakes—for example, the removal of cerumen; but to those which he generally passes on to the specialist—for example, the mastoid operation—only brief reference is made." Nevertheless, we think that the student wants to know more about the operation for acute mastoiditis than that it "consists in opening the antrum and removing any diseased bone found, and draining; some operators, however, close the wound." About three-quarters of a page is devoted to the radical mastoid operation, but in neither case is it mentioned that the cavity is packed, and no account is given of the after-treatment, which often falls to the lot of the general practitioner, and which is all-important to the final success of the case. As no details of the operative procedure are given, the six large illustrations of the surgical anatomy of the parts appear superfluous. The style of writing is somewhat loose, and the arrangement of subjects rather haphazard; thus, hay fever, rhinorrhoea, and vascular neuroses are not placed near together, while rhinoscleroma, leprosy, and glanders are separated from syphilis, tubercle, and lupus by many paragraphs. The paragraph headed "Organic affections of the nose" is devoted entirely to perversions of smell, and occupational deafness due to exposure to noise comes under "toxic causes" of internal ear disease. The headings of the chapters and paragraphs are, indeed, so erratic as to cause confusion, and one often finds the account of a disease interrupted by a new heading in capitals, while a new subject is begun without the distinction of a fresh heading. Having made these criticisms, it remains to say that the book shows evidence of a wide

knowledge and experience of the subject. Errors are few, though in dealing with the treatment of syphilitic nerve-deafness the remark that "later on injections of pilocarpin may be tried" is an inadequate reference to a method of treatment the value of which lies in its early application. But the teaching is in general sound and practical.

A small manual written for students and practitioners can only achieve success if it offers real help in the recognition and treatment of disease. This, we fear, is just what Professor COOLIDGE's little book on *Diseases of the Nose and Throat*² fails to accomplish. Professor Coolidge writes in a pleasantly facile and discursive style, but his descriptions of pathological processes lack precision and omit details which give a clear clinical picture of disease and assist the practitioner in the understanding and management of the individual case. Thus, the paragraph on tuberculosis of the pharynx does not mention that it is painful, and that it usually occurs in the latest stage of consumption; among the causes of anosmia it is said that "it may be a symptom of some constitutional weakness or nervous instability"; of the diagnosis between nasal and cerebro-spinal rhinorrhoea it is only stated that it is possible by chemical analysis, "but sometimes uncertain on account of the similarity of the fluids." The diagnosis between antral and frontal empyema is hardly discussed and no mention is made of Fraenkel's posture test; while the causes of antral suppuration "may be a foreign body, some suppurating focus, possibly connected with the teeth, discharging into it, or a diseased condition of the antral wall." In the sections on treatment, the doses of drugs are not systematically given; that in the after-treatment of antral operations "if packing remains in the antrum it should be removed as soon as it can be dispensed with" is rather vague; and so is the statement that after the frontal sinus operation the skin wound is "brought together and sutured, except when it is considered safer to keep it open temporarily." Two measurements only are given in the article on bronchoscopy and oesophagoscopy—from the incisor teeth to the bifurcation of the trachea, "about fourteen and one-quarter inches," and to the cardiac orifice, "about fifteen and three-quarter inches"; the latter is unnecessarily particular, seeing that the distance varies by an inch or more in different individuals, and the former is $4\frac{1}{2}$ inches in excess of the measurement usually given. Exception must be taken to the advice to remove nasopharyngeal fibromata with an *écraseur*. The author states that "in some cases most of the growth can be removed in this way," and does not appear to realize the dangers of incomplete removal.

SURGERY.

UNDER the title *Back Injuries and their Significance*³ Mr. A. McKENDRICK has written an interesting little book. Its object is to throw some light on the class of cases which bulk so large in courts of law, and is intended to help not only the medical practitioner but the lawyer. As the author points out, it is in the minor rather than in the major injuries that difficulty as to diagnosis and doubt as to treatment chiefly arise. Cases of strained back are fully considered, and interesting suggestions made with regard to electrical testing by means of condenser discharges. Mr. McKendrick is surgeon in charge of the x-ray department at the Royal Infirmary, Edinburgh, and hence writes with authority on the subject of radiographic diagnosis. The book throughout is very helpful and shows well how necessary it is to be systematic and accurate in examining and reporting on any case which may eventually find its way into court.

A Manual of Surgical Anatomy,⁴ by L. BEESLY and T. B. JOHNSTON, has recently been published. It resembles

¹ *Diseases of the Throat, Nose, and Ear*. By W. H. Kelson, M.D., B.S., F.R.C.S. Eng. London: H. Frowde, and Hodder and Stoughton. 1915. (Demy 8vo, pp. 286; 6 plates, 89 figures. 8s. 6d. net.)

² *Diseases of the Nose and Throat*. By A. Coolidge, A.B., M.D. Philadelphia and London: W. B. Saunders Company. 1915. (Post 8vo, pp. 360; 68 figures. 6s. 6d. net.)

³ *Back Injuries and their Significance under the Workmen's Compensation and other Acts*. By A. McKendrick, F.R.C.S.E., etc. Edinburgh: E. and S. Livingstone. 1916. (Cr. 8vo, pp. 179; 14 figures. 2s. 6d. net.)

⁴ *A Manual of Surgical Anatomy*. By L. Beesly, F.R.C.S. Edin., and T. B. Johnston, M.B., Ch.B. London: H. Frowde, and Hodder and Stoughton. 1916. (Cr. 8vo, pp. 571; 164 figures. 12s. 6d. net.)

in appearance a volume of Cunningham's *Manual of Practical Anatomy*, and the general arrangement of the book closely follows that adopted in that well-known book. Several pictures from it, which have, in the course of time, become firmly fixed in memory, will be recognized. The new figures and diagrams, of which there are many, are drawn by Mr. J. T. Murray, and are excellent. In addition, there are many useful radiograms, illustrating the positions of the epiphyseal lines and other subjects. The book includes in its scope something more than surgical anatomy, for the authors have wisely described many of the operations of surgery from the anatomical point of view, without, however, considering surgical technique. They have adopted the new anatomical nomenclature, but have taken pity on the older of us by adding the old-fashioned names where there is any difficulty. It has sometimes been said that anatomy should be taught by operating surgeons, as they are better able to appreciate what is really essential to the medical student. Without going as far as this, it is certainly true that much anatomy is learnt in a rather unintelligent way, without any heed being paid to its surgical significance. The book shows evidence of a clear grasp of practical points, and there is no doubt that every second-year student would do well to possess it, using it as a companion to his manual of anatomy in the dissecting-room. He would find that its study would greatly lessen his labours at a later date, when watching operations and working in hospital, and eventually when presenting himself for his final examination.

The Clinics of Dr. J. B. Murphy at Mercy Hospital Chicago,⁵ published in the form of a sturdy two-hundred-page volume six times a year, is a periodical that has now completed its fourth year of existence. It is composed of *viva voce* accounts of surgical cases, the operations that were done upon them, the results obtained, and any particularly interesting points for discussion that might arise in connexion with them. Dr. Murphy's clinic is famous, and the variety of the cases with which he has to deal is very great; the result is that his bimonthly review is of no little interest to the surgeon. It is inevitably a superficial production, time and opportunity for the profound study of the cases being, apparently, to seek. But it has all the value that attaches to the ephemeral handiwork of an exceptionally gifted operator.

INCOME TAX.

THE assessment of income tax is affected by upwards of fifty different Acts, and *Pratt and Redman's Income Tax Law*⁶ constitutes a successful attempt to classify and render intelligible the existing chaotic accumulation of statute law. Generally the condensations avoid the danger of ambiguity, but there are exceptions. For instance, in dealing with the allowances for depreciation, Mr. Redman condenses the phrase "trade, manufacture or concern in the nature of trade," by omitting the qualification of the word "concern," whereas it is on that very qualification that the authorities apparently rely in holding that depreciation is not allowable in the case of assessments on professional men. Deduction for rent in calculating profits is not, as the author suggests, subject to restriction according to the Schedule A. assessment, which is material only where the premises are owned and no rent is actually paid. The payment of life assurance premiums carries with it a right to receive an "allowance," but is not a deduction in the same way as business expenses, and would more properly be dealt with fully in Chapter IX than among the deductions allowable under Schedule D. The case law is admirably selected and introduced by way of footnotes, and the book has been brought thoroughly up to date. It includes the text of the more recent Finance Acts and a chapter on excess profits duty, but fortunately the latter is of little interest to medical practitioners.

ORDEAL BY BATTLE.

WHEN OLIVER'S *Ordeal by Battle*⁷ was published, in June, 1915, it was eagerly read by men who had grown weary of party shibboleths, and wanted to think for themselves in a desperate effort to understand how this world catastrophe had come upon us. The book frankly discussed the share of responsibility of all of us in bringing it about; our sins of commission and omission—alike of those who were foolish enough to believe in "wait and see," and those who, though they saw, were weak enough to wait. The author was one of those who sat at the feet of Lord Roberts when he tried to arouse the country to the need of national service. The book, therefore, contains a trenchant criticism of the paralytic policy of the decade before the war, but it does not spare the party which was in opposition throughout the greater part of that period. We cannot do very much more than announce the publication of a cheap edition slightly abridged, congratulate the publishers on having brought it out in a handy form and good print, and express the opinion that every one who desires help in thinking clearly should spare the shilling for its purchase. We may perhaps add this much—a great deal has been written about the stupidity of the Germans in their misunderstanding of the psychology of other people. Mr. Oliver shows very cogently how the Germans may fairly retort that we misunderstood theirs. Not only the rank and file of us, but the leaders. The psychology of Lord Haldane, for instance, will probably be still the subject of speculation in the twenty-first century, possibly by the Gibbon of that day. This cheap edition of *Ordeal by Battle* is abridged, but chiefly by condensation of the discussion of the German aspirations and preparations, the least important part to us at this time, and the author has written an introduction which is an appeal to the country to-day; it concludes with the quotation from one who has lost his life in this war: "Under a hesitating commander one of the greatest dangers lies in the fact that it is always possible to produce sound military reasons for doing nothing"; and Mr. Oliver adds, "This is true not only of operations in the field, but of the political conduct of war."

NOTES ON BOOKS.

THE *Medical Register*⁸ for 1916 has been issued. It contains the customary table showing the number of persons whose names were entered in, added to, or removed from the *Medical Register* from 1892 to 1915 inclusive. The average number added by registration for the last twenty-four years was 1,284, and for the last five years 1,265. The average for the five years down to and including 1914 was 1,172. The actual numbers were 1,526 in 1915, 1,433 in 1914, and 1,168 in 1913. The total in 1915 included 181 colonial, and 88 foreign registrations. The total number of names in the *Medical Register* for 1915 is 43,225, as compared with 37,671 in 1914, and 41,940 in 1913. The number of names on the colonial list in 1916 is 692, and on the foreign list 125.

The *Dentists' Register*, 1916, has also been issued. It contains 5,453 names. In 1913 the number was 5,140. Of those now on the register 4,005 are graduates or licentiates in dental surgery, 9 have colonial licences, and 14 are foreign dentists. The number of persons registered on their own declaration as in bona fide practice of dentistry is 1,425, but of these 7 have medical or surgical qualifications.

To those who are interested in the scope and working of the many various scientific and learned societies in Great Britain and Ireland, and some others as well, the *Year Book* compiled from official sources and published by Messrs. Griffin and Co.⁹ will be of great service. It is now in its thirty-second annual issue. It contains outlines or details of the work of the various societies, with lists of their officers, accounts of their meetings, and details of their published work that in many cases would escape any but local notice if it were not for the *Year Book*. The

⁹ *The Year Book of the Scientific and Learned Societies of Great Britain and Ireland.* Compiled from official sources. Thirty-second annual issue. London: C. Griffin and Co., Ltd. 1915. (Demy 8vo, pp. 357. 7s. 6d.)

societies concerned are classified in fourteen sections; the section devoted to medicine covers thirty-seven pages. Particulars are given of certain of the Government institutions for purposes of reference.

The fifth German edition of Professor ORTNER's well known textbook of treatment¹⁰ has been translated by Dr. BARTLETT and edited by Dr. POTTER for the benefit of American medical practitioners. The text is divided into sixteen sections, in which are considered the treatments advisable in the diseases of the various organs and systems of the body. The pathological physiology of the diseases is touched upon in order that the reader may have some scientific basis for the lines of treatment he is advised to adopt. Numerous prescriptions are given, altered so as to conform to the American *Pharmacopoeia*. The German original attaches no little importance to the resources of diet, climate, hydrotherapy, and other methods of treatment. The translators, recognizing the importance of this characteristic, have adapted these references to the needs of practitioners dwelling in America, so far as possible. The translation has been well done. The many pitfalls presented by the spelling of the prescriptions (which are given in Latin) have not all been avoided. The book forms a thoroughly sound and conservative manual of treatment. Its previous English editions have been well received, and we can commend the new edition.

¹⁰ *Treatment of Internal Diseases for Physicians and Students*. By Professor N. Ortner. Edited, with additions, by N. B. Potter, M.D. Translated by F. H. Bartlett, M.D. Third edition in English; revised and reset from the fifth German edition. Philadelphia and London: J. B. Lippincott Co. 1915. (Med. 8vo, pp. 653. 21s. net.)

MEDICAL AND SURGICAL APPLIANCES.

An Electro-Medical Apparatus.

A NEW apparatus of the "universal" type for electro-medical applications has been introduced by the Medical Supply Association (167-185, Gray's Inn Road, London, W.C.) under the name of the "Galvanostat." Its purpose is to use the electrical supply from the main, no matter at what voltage, or whether continuous or alternating, to provide a current for galvanization, ionization, electrolysis, and the testing of muscular reactions. The current is passed, by way of suitable resistances, into a vessel of water, and by an ingenious arrangement of electrodes the transmission to the patient is regulated by rotating a disc of vulcanite over a graduated celluloid scale so as to furnish any degree of variation from absolute zero up to 500 milliamperes. The smoothness of the adjustment, the steadiness of the current, and the fact that there is no danger of the patient getting into direct contact with either the positive or negative side of the supply, are strong points in favour of this apparatus, and an additional recommendation is its surprisingly small size and its portability.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE thirty-third annual general meeting of the society was held at its offices, 300, High Holborn, W.C., on March 28th. Dr. F. J. ALLAN, who presided, in presenting the annual report, said that since the war broke out the experience of all insurance societies had been exceptional. The amount of new business had been less than in previous years, but it was substantial, and in the circumstances, with a net gain at the end of the year of seventy new members, was satisfactory. A considerable proportion of the members had increased their insurance for sickness benefit up to 12 guineas a week. As some had applied for insurance for larger amounts, the committee were recommending a further alteration in the rules to enable this to be done; the society safeguarded itself in granting such insurance by requiring a guarantee that the sum insured for was less than the applicant's income. Nearly £20,000 had been paid during the year to members in sickness and accident benefit, an average of £610 per 100 members; this was the largest sum in the experience of the society, but proportionately to the number of members at risk the amount was less than in 1913, when it was £627 per 100 members. During the year one-fourth of the members had to avail themselves of the society's help, and he considered that if that fact was appreciated by the profession the society would have a much larger membership. Though there were many companies offering insurance for sickness and accident, no other company or

society could offer such good terms. From the separate list presented it would be seen that there were 450 members on active service last year; the claims from these were less than 10 per cent.; five members had died from wounds or sickness contracted on service. The decision of the society not to charge extra premiums either for sickness or life assurance had been much appreciated, and had led to a certain amount of new business. New members, however, were not accepted for more than 6 guineas a week insurance. Although the society offered an endowment insurance payable at 65, the absence of an annuity fund had been felt to be a defect, and in order to meet the deficiency the committee had consulted Mr. S. G. Warner, F.I.A., who had drawn up a scheme which was before the meeting. Holders of annuities would be given several options, and in the event of death or surrender before the age of 65, all the premiums paid, except the first, would be returned with simple interest at 3 per cent. per annum. The scheme was based on the most recent life tables, which showed greater longevity than previous tables, yet the improved investment facilities made it possible to carry out on quite safe lines the scheme recommended by the actuary. Unfortunately, members holding annuity policies under the old tables could not transfer to the new proposal. Considerable depression had taken place in the value of high class securities, and if the society had to realize its investments it would suffer a loss, but an insurance office under normal circumstances never had to contemplate the possibility of liquidation; all that really mattered was the safety of its income. The bulk of the securities held by the society were repayable at par, and consequently no loss could accrue, but at the quinquennial valuation the actuary had to value the investments at the price then obtaining. In order to meet any apparent deficiency the committee had considered it desirable to make provision for it by the formation of an investment reserve account, and to set aside some £4,000 for that purpose. It was also proposed to keep the surplus balance of the management fund in hand to meet emergencies that might arise. The Chairman then referred to the death of Mr. Addiscott, who had acted as secretary of the society since 1893, and who on his retirement from that post was appointed actuary in order that the society might have the advantage of his long experience and sound judgement. The society had also to mourn the loss of Dr. G. A. Heron, one of its trustees, who took great interest in its work. The Chairman then formally moved the adoption of the report, which was seconded by Dr. MAJOR GREENWOOD and carried, after Dr. VINAGE had made some observations.

An alteration of Rule IV, to allow a member to insure for more than £12 12s. per week full pay, was carried, as was the alteration necessary to reopen the annuity fund on the lines suggested by the committee.

HEALTH OF MUNITION WORKERS.

THE Health of Munition Workers Committee, appointed by the Ministry of Munitions, under the chairmanship of Sir George Newman, has issued four more memorandums.¹

Of these, the first in order, on industrial fatigue and its causes, is perhaps the most important, since it deals with general principles. This being the case, we hope to refer to it more fully in a subsequent issue.

The next memorandum, on special industrial diseases, deals with a number of substances now extensively used in the manufacture of high explosives which may produce symptoms not hitherto familiar to the majority of practitioners. Of tri-nitro-toluol (also known as trotyl and T.N.T.), operatives employed in its manufacture and in loading it, either pure or mixed with other substances, into munitions have been found affected with unusual drowsiness, frontal headache, eczema, and loss of appetite. Exceptional cases may occur with sudden collapse after a few hours' work on a hot day, but generally the symptoms are at first slight, and, if exposure ceases, quickly disappear. If, however, the exposure be continued, the symptoms tend to become more severe, and may be associated with cyanosis (ashen grey and livid colour of the lips); shortness of breath, vomiting, anaemia, palpitation, bile-stained urine, constipation, rapid weak pulse, pains in

¹ No. 7, Industrial Fatigue and its Causes (Cd. 8213), price 1½d. No. 8, Special Industrial Diseases (Cd. 8214), price 1d. No. 9, Ventilation and Lighting of Munition Factories and Workshops (Cd. 8215), price 1½d. No. 10, Sickness and Injury (Cd. 8216), price 1½d.

the limbs, and jaundice. In a few cases profound jaundice, with danger to life, has supervened, and even death has resulted.

Other explosives discussed are tetryl (tetra-nitro-methyl-anilin), during the manipulation of which a light dust, which may cause troublesome eczema, is produced; and fulminate of mercury, which involves the liability to mercurial poisoning and eczema.

There is a section on tetrachlorethane, which is a solvent for acetate of cellulose, and is an ingredient of the dope varnish applied to the canvas coverings and tapes of aeroplane wings and bodies, in order, by impregnating them with cellulose, to render them impervious to moisture and air. The poisonous effects of this substance were discussed by Dr. W. H. Willcox in the *JOURNAL* of February 26th, p. 301.

It is pointed out that the demand for explosives, nearly all of which are products of nitration, has introduced increased risks of exposure to nitrous fumes, which arise not only in nitrating substances involved in the manufacture of explosives, but also in the manufacture of nitric acid itself. Here reference is made to a memorandum recently issued by the Factory Department of the Home Office.

There are notes also on lead and on the dermatitis which may be produced by some of the substances already mentioned, and also by contact with certain fluids used to lubricate and cool metals in engineering works.

Memorandum No. 10, dealing with sickness and injury, is a continuation of No. 8. It points out that facilities for prompt treatment of all cases of sickness and injury are of special importance in factories where poisonous substances are used, that organization of treatment is necessary, and that it may be of a simple kind. A local dressing station or aid post should be established in each workplace for minor injuries, and a central dressing station or surgery for more serious cases, or those requiring continuous treatment. The aid post should be under the care of an officer (preferably a foreman or forewoman) trained in first-aid work, and the central dressing station in charge of a competent person with knowledge of ambulance work, with a trained nurse on regular duty, ambulance assistants being selected from employees trained in first-aid work. It is stated that many large works now have a medical officer on the staff who is responsible for the supervision of the surgery, and available for serious cases before removal to hospital.

We would counsel all medical practitioners who practise in districts where munition works exist to obtain copies of these two Memorandums (Nos. 8 and 10). They can be obtained through any bookseller.

Memorandum No. 9 deals with the ventilation and lighting of munition factories and workshops, and has an appendix discussing localized exhaust ventilation.

The memorandums³ issued by this Committee, though they vary in interest, are all of importance and are well worth preserving; the Committee, indeed, seems to be in the way of producing a sort of handbook on industrial diseases which, though it will have special application to certain industries, will deal with many questions of general application to all workshops and factories.

³ Notes on previous memorandums have been published in the *JOURNAL* of December 11th, 1915, pp. 865, 866; January 15th, 1916, p. 102; February 19th, p. 282.

MADAME DARD, widow of Dr. Dard of Dijon, has left the whole of her estate, after the payment of certain legacies, to the Association Générale des Médecins de France. It is estimated that the association will receive £40,000 to be used for the benefit of the widows and orphans of members.

THE Italian Society for the Study of Malaria, of which Professor Angelo Celli was the founder and the animating spirit, is appealing for funds to be applied to the erection of a monument in his memory in the Roman Campagna, the scene of Celli's efforts in the battle against malaria. Subscriptions may be sent to the treasurer of the society, Professor Alessio Mazari, Via Agostino Depretis 92, Roma.

At a meeting held on March 6th the trustees of Columbia University, New York, decided to admit women as students in the medical faculty as soon as the present school buildings can be altered to furnish proper accommodation for the purpose. For more than twenty-five years efforts have been made to induce the authorities to open the medical department to women.

NATIONAL ASPECTS OF MATERNAL AND INFANTILE MORTALITY.

A REPORT on maternal mortality in connexion with child-bearing and its relation to infantile mortality¹ has been prepared by the medical officer of the Local Government Board in England, in continuation of previous reports dealing with other aspects of the subject.

The present report is divided into four parts. The first deals with the decline of the birth-rate and death-rate, and with variations in infant mortality; the second and third with the maternal deaths in connexion with childbearing and their causes; and the fourth with public health administration in relation to maternity.

In his introduction Dr. Newsholme says that the report shows "that childbearing is still associated in some parts of the country with very excessive mortality, and in every part of the country with much avoidable sickness and mortality," and adds: "In order to secure healthy infancy and childhood it is necessary that, both during pregnancy and at and after the birth of the infant, increased maternal care and guidance and medical assistance should be provided."

The maximum birth-rate recorded in England and Wales occurred in 1876, when it reached 36.3 per 1,000 of population; since then it has fallen, and in 1914 it was 23.8. The total number of births in 1914 was 878,882, but if the rate of 1876 had been maintained it would have been 1,346,719. The apparent shortage is, therefore, in round numbers, 467,000. The effect of this fall upon the total population of the country has been masked by the decline in the national death-rate which has also occurred, so that the rate of natural increase of the population in 1901-11 remained as high as in 1891-1901. Emigration, however, reduced the rate of increase by 1 per cent. in the last decade. While admitting that the national death-rate can still be largely reduced, Dr. Newsholme points out that, "as the average age of the population increases, the possibility of maintaining the present natural increase by maintenance of the present birth-rate, and by saving of lives will diminish. . . . If contemporaneously the present rate of decline in the national birth-rate continues, it is not difficult to foresee that eventually births and deaths will balance, and the population of England and Wales will, apart from migration, become stationary as it becomes older."

Statistics are quoted from the Census Report, 1911, showing the total increase of population in certain European countries during thirty years. Expressed in percentages they are:

	United Kingdom.	England and Wales.	German Empire.*	Belgium.*	France.
1881-1891 ...	11.1	11.7	9.3	9.9	1.8
1891-1901 ...	12.1	12.2	14.0	10.6	1.6
1901-1911 ...	9.1	10.9	15.2	10.9	1.6

* Period 1880-1910.

The influence of migration on the population of Ireland and Scotland is probably the cause of the discrepancy between the figures for the United Kingdom and for England and Wales; and this seems to be confirmed by the fact that the loss of England and Wales through migration in the several periods appears to have been 2.32, 0.22, and 1.54 per cent. respectively.

Such statistics illustrate the national importance of the subject, and when every allowance is made for the effects of emigration, they do not materially touch the validity of the conclusion that the diminution in the rate of increase in the population of the United Kingdom is due to the diminution of the ratio of the number of infants born to the population.

The phenomenon is not peculiar to this country, and is not in it so marked as in some others, so that its causes must be looked for in general conditions which are affecting all the nations of modern Europe, as well as the Overseas Dominion and apparently the United States of America also, for the statisticians of the United States have concluded that the birth-rate has been declining very rapidly among Americans of the second and later generations.

¹ Cd. 8085. Price 7d.

The following table,² compiled by Dr. Louis Parkes, exhibits what has been happening in a compendious form:

Table showing the Decrease in the Mean Birth-rates between 1887-8-9 and 1910-11-12, a Period of Twenty-three Years.

7-9.	5-7.	3-5.	Increases.
Hungary ... 8.2	Austria ... 6.7	Norway ... 4.9	Bulgaria ... 3.6
Australia ... 8.0	Belgium ... 6.4	Sweden ... 4.6	Ireland ... 0.3
Serbia ... 7.8	Italy ... 5.8	Denmark ... 4.5	Roumania ... 0.3
Germany ... 7.7	Finland ... 5.4	France ... 4.1	
England and Wales ... 7.0	Scotland ... 5.3	Spain ... 4.0	
	Netherlands ... 5.3	Russia ... 3.7	
	New Zealand ... 5.0	Switzerland ... 3.3	

It is evident from this table that, with the exception of Bulgaria, with a decided increase of 3.6 in the birth-rate, and of Ireland and Roumania with very slight increases, the birth-rates of most of the other nations which furnish registration statistics have been lowered in the course of the last quarter of a century, and some very considerably lowered. It is now generally admitted, both in this country and abroad, that the lowered birth-rate is not due to natural causes, such as a higher average age at marriage, or to a natural decrease of fertility, or even to a lower rate of illegitimate births. It is believed to be due, in most part, to voluntary restriction, the general incentives to which must be universal amongst the nations, and must be of very various character, the kind of incentive that is effective in Australia or New Zealand differing materially from that which is operative in Hungary or Serbia.

Dr. Parkes expressed the opinion that in the more highly civilized and industrialized countries the causes were a desire for a higher standard of social comfort, a disinclination on the part of married women to devote all their lives and energies to the rearing of the future race, and their desire for a larger share in the political and other privileges enjoyed by men, combined, in the case of both parents, with a doubt as to what the future may have in store for the offspring. Amongst the more intelligent of the working classes there may be fears of over-population, of periodical trade depressions and unemployment, and amongst the middle classes similar fears, due to the overcrowding of the professions and the uncertainties of a commercial career, where trusts and great trade combinations seem to hold the field. "With more occupations open to women as the result of the war, or of political changes following the war, both single and married women will have careers open to them which will in the mass militate against a high rate of national fecundity; and we may," he considers, "expect that social changes of this character will accentuate the further fall of the birth-rate for some years to come, which must result from the destruction of so many males who in the natural course of events, if unmarried, would have become husbands and fathers, and, if married, would have increased the number of their children."

The main topic of Dr. Newsholme's report, however, is the consideration of means the State and municipalities can take towards the reduction of infant mortality. Over 21 per cent. of the deaths of infants under a year old, and nearly 33 per cent. of the total deaths in the first five years of life, are due to infective diseases, including measles, diarrhoea and enteritis, whooping-cough, and tuberculosis; manifestly many of these deaths could be prevented if we knew how. In the case of measles and whooping-cough we do not, and in the case of the others results have so far fallen short of expectations.

A hopeful sphere for salvage work is to be found among the causes of death due to conditions operating at or before the birth of the infant. Those attributed to premature birth, atelectasis, and injury at birth, account for no less than 23.6 per cent. of the deaths in the first year of life, and for 15.4 per cent. of all deaths in the first five years. Over 12 per cent. of infantile deaths are ascribed to "atrophy, debility, and marasmus," and of these probably a large portion are due to antenatal infection, and therefore preventable also. The effect of syphilis in causing deaths, post-natal, but much more antenatal, is for various reasons hidden under the present system and scope of infantile deaths registration.

We need not now attempt any detailed examination of the parts of the report which deal with the maternal loss

of life from puerperal fever and from other accidents and diseases of pregnancy and childbirth, since the facts are well known and admitted. So new is much of the work included within the scope of antenatal clinics, prematernity wards, prenatal nurses, and the like, that it has not yet found its way into the textbooks of midwifery. Antenatal care is the application of preventive medicine to pregnancy in the common interest of both mother and infant; the antenatal clinic may play a large part in it, directly among the wage-earning classes and indirectly among others. It may perform at least five functions: (1) The expectant mother may be advised as to the special hygiene of her condition, and as to the best preparations for the birth of her infant; (2) much needless suffering may be avoided by giving advice and treatment for the minor disabilities of pregnancy, such as dyspepsia, constipation, varicose veins, and bad teeth; (3) more serious conditions, such as albuminuria, with its veiled threat of eclampsia, can be looked for, discovered in time, and treated with success; (4) in the case of patients attended by midwives arrangements can be made to obtain medical assistance if needed; and (5) the conditions which bring an expectant mother in an exhausted state to face the strain of labour can be avoided, and, if necessary, unsuitable home conditions may be replaced by more favourable hospital ones. Such experience as there is tends to show that women, if they are suffering, will go to an antenatal clinic, when they know of its existence.

It would be a mistake to promise much until we know a good deal more, but it can hardly be disputed that work along the lines of maternity and child welfare centres, such as infant health visiting, infant consultations, and schools for mothers, has already done much good in all districts in which it has been widely and wisely applied. This is well brought out by some statistics for Chelsea given by Dr. Parkes, showing, among other things, the birth-rates and infantile mortality-rates in the whole borough and in certain limited classes.

Table showing Birth-rate, Infantile Mortality-rate, Death-rate, and Rate of Increase in Chelsea (Census Population 66,385).

3-year Periods.	Birth-rate.	Infant. Mort. Rate.	Death-rate.	Rate of Increase.
<i>Chelsea Borough.</i>				
1906-8	21.9	121	16.3	5.6
1909-11	20.0	106	15.3	4.7
1912-14	18.7	77	13.9	4.8
<i>Industrial Dwellings, Superior Class.</i> <i>Population 1,250.</i>				
1906-8	36.0	67	11.2	24.8
1909-11	28.0	75	8.8	19.2
1912-14	26.4	61	10.4	16.0
<i>Industrial Dwellings, Inferior Class.</i> <i>Population 1,265.</i>				
1906-8	30.8	138	19.8	11.0
1909-11	30.8	119	19.0	11.8
1912-14	26.1	71	11.9	14.2
<i>Seven Streets, Lowest Wage-earning Class.</i> <i>Population 3,480.</i>				
1906-8	37.6	180	25.0	12.6
1909-11	37.4	141	24.4	13.0
1912-14	33.8	86	18.7	18.1

The figures are in some instances too small to justify any wide conclusions, but so far as they go they confirm the general belief that the decrease in the birth-rate has been most pronounced in the upper, and the decrease in the infantile mortality-rate in the lower, strata of the population. They suggest that much may be done by wise administration to safeguard infant life, but when we note that the infantile mortality-rate in the intermediate class is lower than that for the whole borough, and in the lowest wage-earning class not much above, the thought will arise whether, for further improvement in the future, we must not rather look to the antenatal clinic, which may tend both to increase the birth-rate by diminishing abortions and stillbirths, and decrease the infantile death-rate by diminishing the number of babies born only to die.

British Medical Journal.

SATURDAY, APRIL 1st, 1916.

SURSUM CORDA.

THE conferences of representatives of local Medical War Committees held last week in Leeds, London, Birmingham, and Bristol, while they afforded opportunity for the discussion of difficulties and ventilation of criticisms of the action and composition of the Central Medical War Committee—criticisms which that Committee is glad to have, and by which it will endeavour, as far as possible, to benefit—gave good reason also to hope that the profession has determined to live up to the great example it has set to all professions and callings during the last twenty months, and to take advantage of the splendid opportunity it now has of completing its task.

The difficulties of the men who may have to go have already received, and must continue to receive, much attention. None of us ought to rest content until everything has been done that can be done to send off the man who has to go with an assurance that his sacrifice is appreciated, and that it will be minimized as much as possible. But let us fix our eyes for a time on the prize to be won instead of the difficulties in the way.

The prize to be won is the proud satisfaction that the medical profession shall have succeeded in providing all the doctors needed by the army of its own free will and by its own efforts. When this war is over there will be a reckoning up. The public knows that the profession has come forward well; it does not realize perhaps how well and at what sacrifices. But when the day of reckoning comes, there are those hanging back now who will wish that they had done more to help their country. The medical profession has much to be proud of in its war record, but the next few weeks will show whether it is to have the distinguished honour of so organizing itself to meet the needs of the army and the civil community that the War Office, when it needs medical men, will only have to ask with the certainty of obtaining as many as are required.

The opportunity is indeed very great. Let us suppose that at this time some organization could approach the Prime Minister and the Secretary of State for War with an offer to relieve all their anxieties as to getting the number of men required for the army. Would not its offer be sure of ready, even enthusiastic, acceptance? But if that same organization was able not only to undertake to provide the men but to do so in such a way as to embarrass as little as possible the civil community, would it not receive the fervent thanks of the whole country? So far as the medical service of the army, to which it owes its first duty, is concerned, the profession is at the present time within reach of being able to make such an offer. The enrolment scheme of the Central Medical War Committee will provide a reserve of medical men of military age from which all the requirements of the army can be met with the minimum disturbance of civil arrangements and the minimum inconvenience and loss to the medical men

who go. It is a magnificent opportunity, of which the profession must not fail to take advantage. What is the alternative?

It may be taken for granted that the Government will see that the army gets all the doctors it needs, and will, if necessary, use compulsion. There is, we know, a feeling among some medical men in favour of compulsion, on the ground that by it all unfairness would be eliminated. But the success of the enrolment scheme will eliminate all possibility of unfairness, and the result will have been achieved by the efforts of the profession alone. The next few weeks will show whether the profession has sufficient imagination to win for itself this unique distinction. It is the more to be desired that the voluntary enrolment should be successful because the difficulties of the situation, so far as the medical profession are concerned, would be little, if at all, diminished by compulsion. It is true that compulsion would prevent any medical man from hanging back, but all the other difficulties of the situation would remain. It would be no easier to protect the practice of the man who is compelled to go, and compulsion would in no way lessen the difficulties of distributing the work among the men who remain. The chief merit of the enrolment scheme is, as the *Times* pointed out last week, that "it gives full weight to professional opinion. It is no hard-and-fast system of conscription, but a system designed to secure fair treatment and adequate compensation. Doctors will be relieved of the difficulty of deciding whether they should go or stay in civil practice; those who go will have their interests looked after; those who stay will still be afforded full opportunity of serving their country." Undoubtedly it is an essential part of the scheme that those who go shall have their interests looked after; this can only be carried out through the formation of strong local opinion in every district, first in the profession and afterwards among the public. In some areas local war committees have made very careful collective arrangements for protecting the interests of the men who have gone or who may have to go. In other areas men who have gone have made their own arrangements with their neighbours or with locumtenents.

However well private arrangements may have been planned, the fact remains that the man who goes will feel greater confidence that they will continue to be satisfactory if he knows that there is a representative body of his own profession exercising general supervision, and ready at any time to come to the rescue in the event of an unexpected breakdown, due, for example, to the illness of his deputy.

Let it be repeated that the profession now has the opportunity of making a unique gift to the country. If, as there seems good reason to hope, it makes enrolment a success, it will be able to offer to the nation a profession organized for the purpose of both civil and military service. Nothing less ought to satisfy us.

EPIDEMIC JAUNDICE.

EPIDEMIC catarrhal jaundice is a commonplace in the textbooks of medicine, but probably rare in the experience of most British practitioners, although several limited outbreaks have been recorded in this country. Owing to the fact that Weil gave the first thorough description of an epidemic type in 1886, the name Weil's disease is often applied to all forms of infectious jaundice, but it is in the highest degree probable that epidemics of jaundice may be

due to more than one type of infection.¹ The War Office memoranda to which reference is made at page 500 distinguishes three types associated with infection—(a) the catarrhal, accompanying and complicating infective conditions; (b) toxic, or so-called camp jaundice, also commonly known as epidemic or infectious jaundice; and (c) “the so-called Mediterranean yellow fever, or Weil’s disease,” which, it is added, may be regarded either “as a form, and sometimes a malignant form, of toxic jaundice, or better perhaps as a disease *sui generis*, the etiology of which is obscure.”

A disease which agrees clinically with Weil’s description is both endemic and epidemic in western Japan, and quite recently its etiology has been established by the prolonged and painstaking experimentation of a number of Japanese physicians and pathologists.²

In Japan the disease takes the form of a febrile jaundice with congestion of the conjunctivae, muscular pains, albuminuria, and a tendency to haemorrhage. In 1914 an epidemic of 178 cases was observed near Tokyo, in the eastern part of Japan. The disease is due to infection with a new organism, the *Spirochaeta icterohaemorrhagica*. The authors appear to assume that Weil’s disease in Europe is identical with the febrile jaundice observed in Japan, although, as they point out, certainty here will depend on the discovery of the Japanese *Spirochaeta icterohaemorrhagica* in the blood and tissues of the European patients. They also believe that Griesinger’s “bilious typhoid fever” may be identical with Japanese Weil’s disease, although the mortality in the former is 60 or 70 per cent., while it is but 32 per cent. in the latter; it is natural to believe that Weil’s disease may vary widely in severity at different times and in different places.

The discovery of the new spirochaete was announced a year ago. Various animals were inoculated with the blood of patients taken during the first week of the illness; it was found that the guinea-pig developed an acute jaundice with albuminuria, haemorrhages, and conjunctival haemorrhages. The same organism, a spirochaete, was recovered both from the patients and the experimental animals that took the disease. After the seventh day of the disease the patient’s blood often seemed to be free from the spirochaetes; the guinea-pigs developed the jaundice after an incubation period of from six to thirteen days, usually a week. The infection could be transmitted also from one guinea-pig to another; the oldest of the authors’ strains has long passed its fiftieth transmission. The transmission could be effected by intraperitoneal, subcutaneous, or oral injection, and even by inoculation through the shaved but otherwise uninjured skin. Rabbits were found to be comparatively insusceptible to the disease, while guinea-pigs appeared to be more susceptible to it than man. Microscopical examination showed that the spirochaetes occurred in the blood and phagocytic cells of the guinea-pig; in man they were also to be seen in the liver cells, a fact that may explain the occurrence of bactericidal substances in the blood of human beings with Weil’s disease after the second week.

It appears that the new spirochaete, like that of recurrent fever, is an organism living in the blood; it is also seen in the interstitial tissues. In length it measures from 4μ to 25μ , averaging 6μ to 9μ in the blood and 8μ to 9μ in the liver cells of man. The

thickness is probably 0.25μ . The ends are sharp and in most cases hooked; the undulations are irregular, with two or three large and four or five smaller waves. No membrane has been seen nor have flagella been recognized. Staining may be effected with Giemsa’s solution or by Loeffler’s method; when unstained the spirochaetes are invisible except under dark-field illumination. When present in large numbers, some appear to be filter passers, using Berkefeld candles. Their mode of multiplication is as yet uncertain, but this probably takes place by transverse segmentation. They can be cultivated by Noguchi’s method, using guinea-pig instead of rabbit kidney; the optimum temperature is 22° to 25° C. The cultures are odourless and clear, and contain the spirochaetes uniformly disseminated throughout the ascitic fluid; the cultivated organisms resemble those obtained directly from the animal body.

Discussing the mode of infection in Weil’s disease, the authors put forward the interesting and novel view that it often takes place through the skin rather than through the alimentary tract, as Weil believed, or by means of the bites of insects. This method of infection would explain the fact that the disease is readily picked up by Japanese workers in wet coal mines, with or without abrasions of the skin. The clerks working outside the mines, the workers occupied in dry mines, and the inhabitants of the workers’ barracks do not seem prone to the infection. As for the way in which the spirochaetes are excreted by the patients, it is found that these organisms appear in the urine at an early stage of the disease, diminishing in numbers after three or four weeks, and disappearing before the fortieth day.

Examination *post mortem* in twelve fatal cases showed that the spirochaetes were always present in the kidneys in large numbers, but were fewer in the liver and other organs and tissues. There were many more organisms in the tissues of the experimentally infected guinea-pigs than were found in the human subject. It therefore appears desirable to regard the urine as the chief source of infection in Weil’s disease, a matter of great importance from the point of view of prophylaxis. So far as treatment is concerned, both salvarsan and the serum of immunized goats and horses give good results in the guinea-pig infected with the spirochaete, so that there is a sound experimental basis for the clinical use of these substances in human beings with Weil’s disease.

It is always satisfactory to have a severe infectious disorder of unknown etiology, such as Weil’s disease has hitherto been, removed from this large category and put into the list of acute specific fevers of known causation. The authors of the paper now before us appear to have effected this transposition very thoroughly, and to have produced ample experimental evidence of the correctness of the decided views they express. Their *Spirochaeta icterohaemorrhagica* may be accepted as an important addition to the list of organisms producing specific infectious disorders; not the least important part of their work is that illuminating the treatment of the patients stricken with Weil’s disease.

THE TOXICOLOGY OF SALVARSAN.

THE arsenical derivative of benzene¹ introduced for the treatment of syphilis by the late Professor Ehrlich in 1910, and named by him salvarsan, together with its chemical congeners neo-salvarsan, invented in 1912,

¹ On this point reference may be made to the report of a discussion on jaundice at Alexandria published in the BRITISH MEDICAL JOURNAL of February 26th, p. 320.

² B. Inada, Y. Ido, R. Hoki, R. Kaneko, and H. Ito, *Journ. Experim. Med.*, New York, 1916, xxii, 377.

¹ Dr. Willcox uses the word “benzol,” which is, we believe, a German form not generally accepted by English chemists.

and sodium-salvarsan, in 1913, are now generally recognized as the most rapidly acting and most powerful of the drugs at our disposal for curing that disease. So far as this country is concerned, the import of these drugs came to an end with the outbreak of the war in 1914. The result has been that the manufacture of salvarsan has been undertaken here, and the attempt has met with success; the British drug of the same chemical constitution as salvarsan has satisfactorily passed stringent chemical, physical, physiological, and toxicological tests; it has received the sanction of both the Board of Trade and the Medical Research Committee, has been placed on the market under the name "kharsivan," and has been widely employed in this country during the last few months. Most of its users will agree with the opinion expressed by Lieutenant-Colonel Willcox, after the elaborate investigations recorded in his important paper printed on another page of this issue, that it is "practically identical in its physiological and therapeutic effects with salvarsan." Naturally, however, one may expect to find differences of opinion here, the more so because "substitutes" that are "just as good" as the original article are looked upon with disfavour in this country. In addition there is among us an ingrained tendency, which is wholly unjustifiable, to regard the German chemists as superior in ability to our own in the manufacture of synthetic drugs. It is therefore highly satisfactory to find a physician and toxicologist with the experience of Lieutenant-Colonel Willcox making so definite a statement in favour of our home-produced drug kharsivan, as the result of experiments made by himself.

Salvarsan has always been a drug of the proprietary class, made in an atmosphere of mystery under a patent giving a misleading account of its preparation, produced at a small cost and sold at a very high price. It is, therefore, a matter of no little interest to read the chemical tests for its purity described by Lieutenant-Colonel Willcox. The doses tolerated by various animals have been worked out very thoroughly by Hata, Castelli, and others, for both salvarsan and neo-salvarsan. The mode in which the drugs act is implicit in the words "organotropic" and "parasitotropic," and may be illustrated by Ehrlich's experience with the drug atoxyl, the sodium salt of para-aminophenyl arsenic acid, with which, following Koch, he began to work in 1902. It was found that some varieties of trypanosomes were abnormally resistant to atoxyl or "atoxyl-fast"; while, on the other hand, numerous human beings were abnormally sensitive to its action, so that atoxyl was organotropic—or, more precisely, neurotropic—when administered to them, anchoring itself to the patient's nervous tissues rather than to the parasites infecting him, and producing atrophy of the optic nerve. Ehrlich, as is well known, held strongly to the maxim that drugs act only on the tissues with which they are chemically combined, and illustrated his view by the somewhat coarse mechanical analogues represented in his side-chain theory. There is a tendency on the part of physical chemists to replace his chemical conceptions by physical notions, processes of colloidal precipitation, alterations in the permeability of cells or cell membranes, and changes in surface tension or adsorptive power. The two methods of explanation, however, are not incompatible in essence, and both depend in the last resort upon Ehrlich's fundamental principle, expressed sentimentally enough in his aphorism, *Corpora non agunt nisi fixata*—"substances act only when combined."

Lieutenant-Colonel Willcox gives an admirable account of the toxic and even fatal symptoms that may result from the exhibition of salvarsan or kharsivan. As he points out, the pathogenesis of many of the fatal accidents is still obscure. They are not to be explained by anaphylaxis, and to refer them to "a profound autointoxication such as occurs in uraemia" does little to explain their occurrence. It is interesting to learn that the central nervous system is here found to be almost free from arsenic, the inference being that the death was not caused by the action of arsenic as such upon the brain or cord. It appears that the arsenic accumulates in the abdominal viscera for the most part, and to a less extent in the muscles and blood.

Professor Ehrlich himself was inclined to attribute death from salvarsan to excessive vaso-dilatation, as will be seen by reference to a letter he sent to this JOURNAL in 1914,¹ and for the treatment of the dangerous symptoms that may make their appearance after injection of the drug he recommended the immediate and repeated administration of adrenalin. He believed that even the extreme cerebral vaso-dilatation implied in the term "haemorrhagic encephalitis," with its subsequent cerebral oedema and circumvascular haemorrhages, might yield to the prompt exhibition of adrenalin, the patient recovering even from a condition of coma.

From the practical point of view perhaps the most important part of Lieutenant-Colonel Willcox's paper is that in which he gives an account of the modes of administration of salvarsan and neo-salvarsan, and the methods to be employed in combating the unpleasant symptoms, mild or severe, that may follow its use; for it is likely that these drugs will soon be employed in increasing quantities, now that the report of the Royal Commission on Venereal Diseases has been published. The dwellers in towns and cities, who are the chief victims of syphilitic infection, will no doubt receive the advantage of increased facilities for the diagnosis and treatment of their disease, because the Commission urges the necessity of encouraging existing institutions to bestir themselves in this direction, and recommends that they should be subsidized for the purpose from both imperial funds and the local rates.

THE RELATION OF THE EYES TO RIFLE SHOOTING.

A PAPER published some time ago by Dr. Roderic O'Connor,² upon the visual problems of rifle shooting, deserves careful study. To quote Mr. Roosevelt: "The shots that hit are the shots that count. The most valuable fighting man, and the one most difficult to perfect, is the rifleman." Other things being equal, the ability of troops which are armed with the rifle to inflict damage will vary directly with their shooting ability. It is therefore important to take advantage of all possible aids to an increase of the shooting ability and to avoid all hindrances to that end. The army standard of vision is not high, and many soldiers require glasses to enable them to shoot with any degree of accuracy. Of late, numerous writers have tried to prove that good shooting is possible with poor vision, one authority stating that as good shooting can be done by a man having an acuity of $\frac{1}{2}$ as by one with full acuity. He believes that as long as a man can see the front sight clearly he can be a good shot, even though the bull's-eye is blurred. Dr. O'Connor seeks to prove that this view is erroneous. In rifle shooting it is necessary to focus three points—the target,

¹ BRITISH MEDICAL JOURNAL, 1914, 1, 1044.

² Ophthalmology, July, 1915.

the front and the rear sights. It is therefore essential with the usual military sights that the soldier shall possess good power for accommodation to enable him rapidly to focus these objects in succession. When alignment has been secured, the bull's-eye is seen in focus by direct vision, the sights are seen blurred by indirect vision. A presbyope cannot shoot well because he cannot focus the rear sight, and if he use spectacles which clear the sight the target is blurred. The use of a peep-sight enables a presbyope to shoot, and makes it easier for all eyes because there are then only two objects to focus. The act of looking through the peep-sight aligns the sights automatically upon the object, and the rear sight has never to be focussed. Dr. O'Connor considers that the peep-sight close to the eye should be adopted. The aperture should be 1 mm., and the sight should be 1 in. from the eye. The peep-sight being close to the eye increases the space between the sights and so makes for accuracy in aim. It also increases the acuity of those who have errors of refraction and reduces glare. To demand with the author that combatants in the line, signal corps, and engineers shall have $\frac{3}{4}$ vision, binocular vision, normal colour perception, and good accommodation, would be, we fear—at any rate, in present circumstances—a counsel of perfection.

BROWN-SÉQUARD EPILEPSY.

In 1869 Brown-Séquard described the production of epileptic attacks in guinea-pigs by violent stimulation of the sciatic nerve. Since that time a number of cases have been recorded in medical literature in which epilepsy supervened in human beings after, and apparently as the result of, severe injuries of the peripheral nerves. A few of these have been collected by Drs. A. Mairé and H. Piéron,¹ who remark on the rarity of these cases, and add two more of their own observation. One patient, a railway employee, had his right hand crushed under the wheel of a carriage in 1886. After this he was only fit for light duty at the railway station. In 1890 he was dismissed for offences against decency in public. He went to law about it, and the medico-legal experts found he was suffering from chronic neuritis of the right arm and attacks of epilepsy. It appeared that the neuritis had been confined at first to the ulnar nerve, and had spread so as to involve the whole brachial plexus; while the epilepsy might take several forms culminating in true epileptic seizures, and could often be provoked by pressure either on painful spots on the scar left by the injury or on the tender ulnar nerve. The second patient, a soldier aged 30, was wounded by fragments of a shell in the right forearm in September, 1914. The wounds healed in December, after much suppuration, leaving extensive scars. In January, 1915, the man complained of headache, vertigo, and noises "as of aeroplanes" in the ears. Attacks of stiffness and tremor of the limbs, with loss of consciousness, occurred both by day and night. When seen in hospital at Montpellier in April the right arm was weak and wasted, and there were various areas of loss of sensibility, hyperaesthesia, and hyperalgesia. The musculo-cutaneous and internal brachial nerves were thickened and tender; other branches of the brachial plexus and cervical nerves seemed to be affected as well. There were no signs of neurasthenia. While in hospital the patient had two or three epileptic or epileptiform attacks daily, varying in degree of severity, preceded by an aura of pains in the right arm and culminating in stiffness and clonic spasms, with loss of consciousness lasting for many minutes. Minor attacks could be brought on by pressure on the musculo-cutaneous nerve. Some improvement was produced by electrical treatment. In June the brachial scars were excised under ether, but the epileptic attacks returned. In August and September treatment of the arm by prolonged hot baths was under-

taken—two hours in water at 104° F. twice a day. After three months the man was very much better; no fits had occurred after September, and the affected nerves were much less sensitive to pressure. The arm and hand were stronger, and were being treated by massage and movements. The authors consider this to be one of the rare cases of true epilepsy reflexly produced by severe peripheral irritation; the patient's family history was such as to suggest a predisposition to nervous disorders. Dr. Pierre Marie,² on the other hand, states that he has never been able to accept the convulsions described by Brown-Séquard in his experimental animals as comparable to epilepsy in human beings. He is inclined to attribute the phenomena displayed by Mairé and Piéron's second patient to hysteria or neuropathy rather than to epilepsy.

PORTRAIT PAINTING AND PATHOLOGY.

CERTAIN portrait painters of world-wide renown are famous for their pictures of pathological specimens of humanity as well as for their portraits of more normal persons. The stock example of this slightly morbid turn of the artistic mind is Velasquez, whose pictures of the various royal dwarfs kept at Court by Philip IV of Spain will be remembered by all who have visited the Madrid Museo del Prado. In the same gallery there are numerous other portraits, painted by Goya and by El Greco, to mention but two names, of pathological specimens of humanity that, to the eye of a medical man, are faithful and unmistakable delineations of mental or bodily disease. And to come down to more recent times and our own country, anyone who has visited the exhibitions of the post-impressionists, cubists, futurists, *et hoc genus omne*, in the last decade, will no doubt have been struck by the abnormality of the types of human beings often depicted. The efforts of these artists, however, are not perhaps of the same artistic importance as those of the Spanish painters already mentioned, and do not call for or deserve the same serious consideration. But even the best known, most successful, and most orthodox of our portrait painters at the present time portray, or find themselves confronted by, sitters who exhibit to the eye of the medical man and pathologist most interesting variations from the normal. In the exhibition of the National Portrait Society now open are numerous works of sterling artistic merit and worthy of the highest praise; the collection is one that should be visited by all who are interested in the art of portraiture. The attention of medical visitors will be particularly arrested by the skill exhibited by not a few of the contributing artists in depicting various pathological abnormalities. Thus, there are portraits of sitters with such banal afflictions as goitre, arrested hydrocephalus, and kyphoscoliosis; in the last instance the sitter's hands are in view, and from the absence of onychocampe and clubbing of the finger tips the pathologist is perhaps justified in concluding that in this instance the kyphoscoliosis was not secondary to pulmonary disease, as it so often is. In another gallery is a good reproduction of the *plica polonica*, or matting together of a head of hair, that is rarely seen in this country but is *ex hypothesi* common in Central Europe. There are also pictures that seem to illustrate to perfection the harmful effects that may follow alcoholic excess. Taken together they form quite a temperance sermon in oils. Other pictures illustrate diseases that are less common. There is, for example, an excellent representation of acromegaly occurring in a young man; a picture of an older man suggesting chronic methaemoglobinæmia, possibly due to the habit of taking aniline-derivative drugs in excess. Another artist has chosen to portray the sitters in a curious light that gives them all the appearances of advanced *post-mortem* decomposition, and here we are presented with a pathological problem that is insoluble for it is evident that the sitters are alive and in

¹ *Bull. de l'Acad. de Méd., Paris*, 1916, lxxv, 80.

² *Ibid.*, p. 92.

the full enjoyment of life. Another picture gives a most successful rendering of left facial hemiatrophy, coupled with a slight degree of the torticollis that sometimes accompanies this rare morbid condition. Certain common disorders are rather noticeable by their absence in this admirable exhibition of portraits. Thus visitors to the annual exhibition of the Royal Academy may always count on seeing pictures of fair English girlhood suffering from enlarged tonsils and adenoids, or from anaemia, in fairly large numbers. In the exhibition now under consideration there is but a single case of well-marked anaemia, and only one or two portraits suggesting the facial deformities associated with chronic nasal obstruction. We cannot conclude this brief review without adding a word of praise for the skill and truthfulness with which the artists concerned have depicted the various conditions described.

"PANTEUTOMANIA."

THE moving pictures of the war have passed in such quick succession before our eyes that already the manifesto issued in the autumn of 1914 by ninety-three leaders of German thought has faded into ancient history and is now almost forgotten. This is, perhaps, a pity, for the document¹ throws a fierce light on the mentality of the German "intellectual." We are glad, therefore, that the Lisbon Society of Medical Sciences is distributing an address delivered by its President, Professor Ricardo Jorge, in which he deals faithfully with the manifesto and its authors.² He describes their deliverance as showing all the symptoms of a collective madness. We need not follow the orator in the torrent of his invective. But something may not unprofitably be said as to the process of mental perversion which has taken place in Germany during the last forty-five years. This Jorge traces in a striking manner. In 1870, he says, France lived imprisoned in her own vanity; for her there was then no science, no art, no literature but her own. A German psychological physician, Karl Starck, discussed this mental condition in a pamphlet published in 1871, in which he maintained that France was really suffering from a psychosis akin to paralytic dementia, or *folie raisonnante*, with predominance of the mania of greatness. The overthrow suffered by her in 1870 produced a great change of spirit, and the disease in turn attacked her conqueror. The symptoms showed themselves very early. In his *Study of Sociology*, published in 1873, Herbert Spencer quotes a German professor as writing to him: "There is, alas! no want of signs that the 'happy contrast to French self-sufficiency' which Germany heretofore displayed is disappearing 'since the glory of the late victories.'" An "esteemed German professor of philosophy" declared that the psychical and ethical sciences would not be advanced by international communion of thought, adding that "if this were possible he did not think it desirable, as it would interfere too much with the peculiarity of German thought." Thus, said Spencer's correspondent, "the finest German characteristics are disappearing in an exaggerated Teutonomania." Another professor contended, with perfect seriousness, that "only one thing is now wanted to complete our German institution, a national costume." Jorge contrasts the attitude of Virchow with the arrogance of the present day "intellectuals" who loudly proclaim their belief that Germany can do no wrong. In 1871 he warned his fellow countrymen of the dangers to which national vainglory would expose them. He added that German scientists were almost all opposed to war—a statement which reads curiously at the present day. It is easy to guess what

the great man who made it would have thought about the "panteutomania," as Jorge calls it, from which the German people is now suffering. The Lisbon professor's address, which was delivered in December, 1914, was violently criticized by Professor C. Mense, editor of the *Archiv für Schiffs- und Tropen-Hygiene*, who speaks of him as an orator driven mad by the calumnies of the enemies of Germany and discharging his soul in a flood of injurious accusations. For this reason the *Archiv* declines further exchange with the *Medicina Contemporanea*, in which the address appeared. Jorge retorts that there could be no better proof of the truth of his view that Germany has gone mad than Mense's effusion. These professorial courtesies make one wonder what is to happen in the intellectual sphere after the war. One learned Teuton has already told the world that henceforth medicine is no longer to be cosmopolitan but wholly German. There are to be no more international congresses and no scientific intercourse between Germany and other countries. Another has declared that "Germany must and will stand alone. The Germans are the salt of the earth; they will fulfil their destiny, which is to rule the world and to control other nations for their good." But we need not be alarmed. The world will manage to get along without German medicine and surgery, for Germany depends much more for its ideas on Great Britain, France, and America than those countries do on her.

HAEMOLYTIC SPLENOMEGALIC JAUNDICE CURED BY THE X RAYS.

PROFESSOR G. JONA, of Venice, has recently described¹ the case of a youth of 18 with what he describes as a primitive acquired haemolytic acholuric splenomegalic jaundice of the Widal and Hayem type, who was cured by the x rays. The patient, when seen for the first time in 1912, was well nourished, anaemic and slightly jaundiced; the urine was free from bile pigment, but contained urobilin. The liver was soft and moderately enlarged; the spleen was enormously enlarged, reaching across the middle line and down to the fold of the groin, and the splenic dullness measured 34 by 19 cm. The faeces contained an excess of pigment; the blood examination showed 50 per cent. of haemoglobin, 2,900,000 red cells and 5,000 white cells per c.mm., with numerous nucleated red cells, anisocytosis, polychromasia, lymphocytosis, and diminished resistance to solutions of sodium chloride. In the eight examinations made of the blood, no malarial parasites were ever seen; the patient's temperature was normal during the seventy-five days he was in hospital. The blood serum contained bilirubin; Wassermann's reaction gave a negative result, and so did von Pirquet's test. After the patient had been treated for a month with Fowler's solution by the mouth and injections of green citrate of iron, without improvement, x-ray therapy was begun. A tube of moderate hardness (7-8 Benoist) was used with a current of a half to one milliampère 40 cm. from the patient, who was screened by an aluminium plate 1 mm. thick. Exposures lasted ten minutes, and were made in groups of three, the anterior, lateral, and posterior aspects of the spleen being irradiated on successive days. These three exposures were repeated at intervals of five days; twenty-one exposures were given between December 5th and January 19th, 1913. The patient's general condition improved at once, and so did his blood count; the spleen diminished in size but slowly, the dullness measuring 27 by 15 cm. in February, 1914; in August, 1915, the dullness measured 15 by 9 cm., and the spleen extended three fingerbreadths beyond the left costal margin, while the liver was normal in size. The haemoglobin reached 70 per cent. in January, 1913, 80 per cent. in February, 1914, and 100 per cent. in August, 1915, when there were still traces of urobilin in the urine.

¹ Comments on the manifesto and the replies from a number of learned bodies throughout the world will be found in the BRITISH MEDICAL JOURNAL, of October 31st, November 28th, and December 5th, 1914, and March 27th and July 24th, 1915.

² *A Guerra e o Pensamento Medico*. Portugal-Lisboa: Edição da Sociedade das Sciencias Medicas.

¹ *Il Policlinico*, Rome, 1916, sez. med., xix, 17.

Professor Jona remarks that there was still a trace of jaundice about the patient in March, 1915. He discusses the case from various points of view, and gives a number of details about the blood examinations that cannot be reproduced here. He considers that the x-ray therapy produced the same results as splenectomy would have done, though more slowly; in 1914 Mühsam collected 14 cases in which the condition had been cured by splenectomy. Professor Jona quotes 2 cases of congenital haemolytic jaundice much improved by x-ray treatment of the spleen; he has not found any case similar to his own recorded in the literature.

ECONOMY IN PAPER.

THE Royal Commission on Paper has issued a further appeal to the public drawing attention to the consequences of the restriction upon the importing of paper and paper-making materials which it has been appointed by the Government to carry out. The restriction reduces the import by one-third, and newspapers, journals, and magazines must correspondingly be reduced in size or weight, or both. The appeal is to the public to be economical in the use of paper, for the restriction of the supply of paper for printing has been for some time in force, and it has been necessary in the case of this journal, as in that of all its contemporaries, to reduce the number of pages and the weight of the paper. We would appeal to contributors to bear the fact in mind when preparing articles for publication. Our contemporary *Nature*, in its issue of March 23rd, announced that it has been found necessary to reduce the size of that valuable periodical, and made an appeal to its contributors to "confine themselves to essentials, points of prime importance, in order that our record of scientific work and events may still be as extensive as possible, though it must necessarily be less detailed." These words put the situation very well, and place the matter on a true ground. They are as applicable to medicine as to science in general. We are well aware that to be brief is troublesome, since it requires more concentration of thought and more labour in composition. It is well worth while to incur these extra pains in the interests of readers and of the advancement of science. The first draft of an essay almost invariably contains repetitions and redundancies, which can be eliminated not only with the saving of space but with increase in clearness.

It is announced from Paris that a sanitary conference of representatives of the Allied Powers has met there during this week for the discussion especially of the prevention of typhus and cholera, the destruction of rats—which are so serious a nuisance in the trenches—and of insects, and questions as to rations.

Medical Notes in Parliament.

Mesopotamia.

On March 23rd Mr. Tennant stated that the new arrangements for the control of operations in Mesopotamia came into force on February 16th, 1915. The commander-in-chief in India received instructions with regard to the military operations in Mesopotamia from the chief of the Imperial General Staff in exactly the same manner as the commander-in-chief in other theatres, but India remained the main base of the forces in Mesopotamia, which was administered by the commander-in-chief in India. Such requirements of the forces as India could not meet were supplied by the War Office from other parts of the empire so far as consideration of general policy did not render this impracticable.

Medical arrangements in Mesopotamia, Mr. Tennant also stated, were primarily under the control of the military authorities in India, but the commander-in-chief

in India had been informed that the Army Council would render him any assistance in medical personnel and equipment. All demands had been met without delay; 120 medical officers, including 40 from Egypt and 205 other ranks, R.A.M.C., had arrived or were on their way. In addition, one British general hospital of 1,040 beds and one British stationary hospital of 400 beds had been sent from Egypt. Both these units were fully equipped. Four Indian general hospitals of 500 beds each, which were in this country, had also been sent. Two of these were fully equipped, and the remaining two consisted of personnel only. From France the Lahore Indian Stationary Hospital of 200 beds and 33 medical officers were under orders. A motor ambulance convoy—50 cars with complete personnel—was nearly ready, and would leave for Mesopotamia early next month. The commission, consisting of Sir William Vincent and General Bingley, after taking evidence in Bombay, left for Mesopotamia on March 10th. Asked whether these two public servants had any special knowledge or experience of medical requirements for an Eastern campaign, Mr. Tennant said that Sir William Vincent was a man of wide administrative experience and had proved efficient in high and responsible official posts, and that Major-General Bingley had had a great deal of staff experience and was well suited for an inquiry into alleged deficiencies in the organization of supplies. These two gentlemen were, Mr. Tennant considered, amply qualified to elucidate the facts and to make a fair, complete, and judicial report upon them, having reference to all aspects of the question. They could procure any technical and expert advice they desired.

In reply to a question by Lord H. Cavendish-Bentinck, on March 23rd, Mr. Chamberlain said that he had learnt that the Joint War Committee of the British Red Cross Society and the Order of St. John, in co-operation with the Indian Soldiers' Fund, offered general assistance direct to the general officer commanding Mesopotamia in July, 1915, and repeated their offer at later dates, and that stores were sent by them to Basra in September, two motor boats in August, and another in October. In December further offers on their behalf had been transmitted. On January 31st the Committee offered to place at the disposal of the Secretary of State the organization of the two societies to supplement the provision made by the Indian Government for the care of the sick and wounded in Mesopotamia. The offer was in the widest and most generous terms. It referred in particular to the possibility of helping in the supply of stores and clothing, medical comforts, drugs and luxuries not included in the scheduled army lists; in the supply of motor ambulances, barges and other vehicles, for the transport of the sick and wounded, and in the equipment of hospitals and the provision of personnel and staff to administer such hospitals. The offer was communicated to the Viceroy, who, having ascertained that its acceptance would not conflict with the organization and arrangements of similar Indian societies, informed the India Office that the Indian Council of the St. John Ambulance Association, which from the outset had actively concerned itself with the Mesopotamia force, would gladly accept assistance. In October, 1915, the Indian Soldiers' Fund made inquiry through the India Office of the military authorities in Mesopotamia as to whether clothing and comforts were needed for the troops, and was informed in reply that for the present the supply in India was sufficient. The Fund Committee had independent evidence that there were sufficient supplies at the base at that time. An offer from the fund transmitted to the Viceroy in December to supply bandages, medical and surgical dressings, and other hospital comforts was gladly accepted, and early in January a large consignment of articles, some contributed by the Joint Committee, was despatched to Mesopotamia. Other offers of which the India Office had no direct knowledge had been made to corresponding societies in India engaged in providing comforts for the combatants and medical supplies for hospitals.

On March 28th Mr. Gwynne asked whether, when the shortage of doctors and nurses and hospital equipment in Mesopotamia was realized by the Government, any endeavour was made to transfer some of the hospital equipment in Egypt not at present being used. Mr. Tennant replied in the affirmative. Aid, he said, was offered as soon as it was realized that aid was wanted.

War.

Army Medical Advisory Board.—Sir Philip Magnus, on March 23rd, asked whether the Government would consider the advisability of reconstituting the Advisory Board to co-operate with the general superintendent in the further organization of the medical service, and, if so, whether regard would be had to the suggestion that had been made by a number of medical men that such a Board should consist of some lay representatives. Mr. Tennant said that he took note of the suggestion, but could not admit that a case had been made out for interfering with the organization as it at present existed. In reply to Mr. McNeill, who asked whether it was not a fact that the Advisory Board was in existence when the war broke out, and that the neglect to call it together was without any proper authority, Mr. Tennant said that Mr. McNeill was misinformed as to the facts, although he (Mr. Tennant) had given him a description of what had occurred at the outbreak of the war in the recent debate. It was, Mr. Tennant added, quite within the competency of the military authorities to suspend the activities of the Advisory Board as and when they might think proper.

Medical Officers with Special Experience.—On March 23rd Sir Philip Magnus asked what steps were being taken to arrange that doctors with special experience in different branches of medicine and surgery who had joined the Royal Army Medical Corps were being employed by the War Office as to utilize to the best advantage their special qualifications. Mr. Tennant replied that every effort was made to employ gentlemen who joined the Royal Army Medical Corps in such a way as to give their individual qualifications every consideration. It was sometimes not practicable to use their services exclusively in one special line of practice, as the need for special work was limited. His information was that these gentlemen willingly gave their attention to work outside their special qualifications when work of that kind was awaiting attention.

Part-time Hospital Work.—Sir Philip Magnus on March 23rd asked a question as to the utilization to a greater extent in part-time work at hospitals, or in looking after the health of troops, of the services of medical practitioners resident in the neighbourhood, so as to release a proportion of the men who had volunteered for whole-time service abroad, or who had been asked to take commissions in the Royal Army Medical Corps. Mr. Tennant replied that the policy suggested was already followed. A considerable number of medical practitioners were already employed in part-time practice, and it was anticipated that this number would be largely increased.

Tuberculous Soldiers.—In reply to Major Astor, on March 22nd, Mr. Tennant said that the number of cases of tubercle of the lung treated out of army funds in hospitals in the United Kingdom on February 29th was 632. The information available did not make it possible to distinguish those who were suffering from consumption alone from those who were suffering from consumption and wounds or other injuries directly attributable to warfare. In reply to another question by Major Astor on the same day, the Chairman of the Joint Committee of Insurance Commissioners said that approximately 2,000 cases of tuberculous soldiers had passed through the hands of the several commissions in connexion with the special arrangements made in April, 1915, for the provision of immediate residential treatment for discharged tuberculous soldiers, and had been provided with treatment. In addition, it was known that a large number of soldiers who became, on or after discharge, eligible for sanatorium benefit had made application for the benefit direct to the local insurance committees, who had afforded treatment without reference to the Insurance Commissioners. The actual number of such cases—including, of course, many cases which arose before the special arrangements were established—could not be obtained without a special return from all insurance committees in the United Kingdom.

Cerebro-spinal Meningitis.—Mr. Chancellor asked a string of questions, on March 22nd, with regard to carriers of cerebro-spinal meningitis. Mr. Tennant, in his answer, said that two cases had arisen from contact with soldiers segregated as carriers at the Fulham Military Hospital; that a carrier of disease could, as a rule, be made not to be a carrier, and that it had been proved that cases of the disease had arisen from contact with persons not themselves suffering from it. Mr. Chancellor suggested that the advice on which the alleged carriers were treated was not based on anything more substantial than an unproved theory, not only not accepted but widely disputed and denied in medical circles. To this Mr. Tennant replied that the carrier theory in this and other diseases had been fully proved, and was widely accepted by the medical profession.

Steel Helmets.—In reply to questions on March 23rd the Minister of Munitions said that reports of a very satisfactory nature had been received on the steel helmets and the necessary steps had been taken to obtain a supply sufficient to meet the requirements of the War Office. A satisfactory pattern was approved some five months ago. Changes were being made to meet the improvements suggested by experience, but already over 300,000 had been delivered. On March 28th Mr. Tennant said that all battalions in the field will shortly be equipped with helmets either of the present or of an improved pattern.

Ration Allowance to Wounded Officers.—On March 22nd Mr. Burdett-Coutts asked a question as to an order of February 28th cutting off the ration allowance of 1s. 9d. a day previously paid to wounded officers. He pointed out that in existing circumstances the homes of many of these wounded officers were broken up when they joined the army, and that therefore the ration allowance when they were home on sick leave, perhaps for a long time, was a consideration to many of them. It had to be remembered that there was no separation allowance for the wives and families of officers. The Financial Secretary to the War Office (Mr. Forster), in reply, admitted that some of the considerations which should have carried weight were not sufficiently taken into account before the allowance was cancelled. The Government proposed to reconsider the question in a generous spirit.

Bonesetters.—In reply to a question by Sir A. Markham, on March 28th, Mr. Tennant said it was true that the War Office had declined to accept the services of Mr. H. A. Barker, together with those of several other gentlemen who were not registered medical practitioners. It was not the intention of the Army Council to direct the medical authorities to employ unqualified men to treat military patients. If this were done, Mr. Tennant added, he felt certain that from no quarter would there be a louder outcry than our soldiers were not receiving the necessary skilled attention than from members of the House of Commons.

WAR PENSIONS.**N.C.O.'s AND MEN.**

The total pension receivable by a man disabled in the war or by his widow or other dependants if he is killed, may be derived from two sources—the funds administered by the Greenwich and Chelsea Commissioners which are ordinary charges on army funds, and the funds at the disposal of the Statutory Committee of the Royal Patriotic Fund Corporation, set up under the Naval and Military War Pensions Act, 1915.

With regard to the pensions paid through army funds by the Chelsea Commissioners, the Financial Secretary to the War Office (Mr. Forster) made a statement on March 22nd. He began by saying that it had been suggested that there was a prevalent belief amongst wounded soldiers that it was undesirable from their point of view to qualify themselves by skill and industry for a trade, because if they did the mere fact that they had become sufficiently skilful to earn their living adversely affected their pensions. It should be clearly understood, Mr. Forster said, that in assessing pensions it did not matter what a man earned at the moment. What was taken into account was his capacity to earn. His pension was calculated on his physical condition.

It would, therefore, be clearly realized that the pension of a man who was earning nothing would be reduced if there was nothing in his physical condition to prevent him from earning, if so inclined. On the other hand, a man earning a very considerable rate of wages might at the same time be drawing a considerable pension. When a man had lost a limb he was treated by the Commissioners of Chelsea Hospital as totally incapacitated for a certain length of time, and he got the full rate of pension of 25s. a week for at least two months after he had been fitted with an artificial limb. It took time for a man to get accustomed to his new apparatus. The man got his full scale of pension for a certain time, say, six months, at the end of which his case was reviewed, his physical condition closely examined, and if the verdict of the doctors was that his physical condition was sufficient to enable him to earn his living to the extent of, say, one-half, his pension was reduced. It did not matter how much the man was earning at that time. If his physical condition was so much improved as to permit him in the open market to earn at least half of the full living, his pension was adjusted on that account, and not on account of the particular amount of money he might happen to be earning at the moment. He wished soldiers to realize that it did not pay them, and ought not to pay them, to refuse to take employment simply for the sake of retaining their pension at the highest scale. It was assessed not by the standard of what they earned, but according to their physical capacity.

In asking for a vote of £1,000,000 to the Statutory Committee, constituted under the Naval and Military War Pensions Act, 1915, the Parliamentary Secretary to the Local Government Board (Mr. Hayes Fisher) made a statement, in which he said that the duty of the Committee under that Act was to grant pensions to supplement those granted by the Greenwich or Chelsea Commissioners and to make provision for the training and employment of disabled soldiers and sailors. The Commissioners would make grants on scales laid down by the Committee on Supplementary Pensions in cases in which a consideration of the circumstances showed that the State pensions were not adequate either to the individual soldier or sailor or his dependants, and also grant pensions in cases of great hardship in which, for one reason or another, pensions had not been given to disabled soldiers and sailors.

The number of disabled men discharged as unfit from wounds and disease who had been awarded pensions and grants by Chelsea Hospital down to March 9th, 1916, was 30,255; 5,470 had received final pensions; 1,356 provisional pensions; and 23,429 conditional pensions, to be reviewed later. Pensions or grants had been refused in 15,105 cases by the Chelsea Commissioners, but that was before the concession made recently rendering it unnecessary for a man to prove that a disease from which he suffered was due wholly or directly to military service; pensions would be given where the disease had been aggravated by military service.

The number of cases of amputation notified to the main hospital at Roehampton down to March 1st was 3,818; of these, 1,628 had already been admitted to Roehampton, and 932 had been discharged with properly fitted artificial limbs, which were a vast improvement on those which used to be served out to the victims of former wars. At present there was a waiting list of 2,027, and cases were being notified at the rate of 300 a month.

With regard to the blind, some 200 had either passed through the training school at St. Dunstan's or would shortly pass through, but it was to be feared that the number would be very much larger before the war ended, and it would be necessary to provide another St. Dunstan, either by giving help to Mr. Pearson or by direct action. For the paralysed it was not possible to do more than provide a home, and this work was being undertaken by those who had started the big hospital at the old Star and Garter Hotel at Richmond. Special provision would also have to be made for nervous cases and would have to be continued for many years after the war.

The State pensions for a widow would be a flat rate—10s. a week until she was 35; 12s. 6d. from that age to 45; and 15s. afterwards. The total number of widows of N.C.O.'s and men reported by the Army Council to March last was 41,500. The separation allowance was continued for twenty-six weeks, and was still being paid to 18,394; 23,106 were actually in receipt of pensions; only 800 had been refused pensions. The number of widows of men in the navy who had been granted pensions was 4,180; the number in receipt of separation allowance was 420, and the number who had been refused pensions 48. Cases in which pensions had been refused would be considered by the Statutory Committee, and it would also consider whether pensions granted should in any cases be increased. The Statutory Committee had come to the conclusion that the income of a widow with children should be made up to two-thirds of the pre-war income, with a maximum of £2 a week. The Statutory Committee would also consider cases of hardship in relation to the education of children or due to exceptional sickness. In addition to approximately 50,000 widows, there were dependants other than widows and orphans who also numbered about 50,000; their case, as also that of persons not now in receipt of any pension, would have to be considered by the Statutory Committee. Mr. Hayes Fisher added that he did not expect the vote of a million now asked for would be sufficient. The National Relief Committee had spent over two millions already in extra separation allowances, mainly for extra rent, and the expenditure was now about £80,000 a month. In the course of a discussion Mr. Barnes recalled the fact that the Verney Committee had recommended the Government to set apart two millions to set up farm colonies, but this, it was estimated, would settle only about 5,000 families. The vote was agreed to.

Pensions for Nurses.

In reply to a question by Mr. Burdett-Coutts, on March 22nd, Mr. Forster said that steps had been taken to institute a special scale of pensions for those nurses who were disabled either by disease or accident wholly and directly due to service, or aggravated by service.

The matter was discussed with the head of the nursing staff, the matron-in-chief, and he hoped that the House would be satisfied that the scale laid down was sufficiently generous to meet the case.

UNITED STATES.

The following notes founded upon the latest report of the Commissioner of Pensions (United States of America), for the use of which we are indebted to the courtesy of the acting commissioner through Mr. Lynn Thomas of Cardiff, are of interest in this connexion:

The (estimated) total number of individuals enlisted on the Union side during the Civil War was a little short of two millions and a quarter (2,213,365).

The number of soldiers and sailors pensioned on account of service during the Civil War was 1,156,160. Of this number, approximately 565,000, or nearly half, were pensioned on account of disability incurred during the war. The remainder were pensioned under various Acts of Congress which do not require that in order to obtain a pension the disability must have been incurred in service in "line of duty."

A claim may be made by a soldier or sailor for a wound or injury received during the execution of his duty, or by accident, or on account of disability due to disease.

It would appear that all claims are referred to the Bureau of Pensions, which is under the direction of a Commissioner, who reports to the Secretary of the Interior.

The report of the Commissioner for the fiscal year ended June 30th, 1915, shows that the number of disability pensions in respect of the Civil War was 45,611, and the amount disbursed in pensions 16,500,000 dols. In 1911 the number of pensions was 113,469, and the amount disbursed nearly 32,000,000 dollars. The death-rate among pensioners, and among pensioned dependants also, is rising rapidly, as was to be expected, remembering that the war came to an end fifty years ago, but the immense time liability of the State may continue in respect of war pensions is shown by the astonishing fact that in 1915 pensions were paid to 134 widows in respect of the war of 1812!

The report does not distinguish the nature of the disabilities in respect of which disability pensions are paid, so that the proportion of those given for wounds and for disease respectively cannot be calculated.

In settling the amount of a pension the Bureau acts on medical reports rendered by examining surgeons or boards of such surgeons appointed in every State, to the number of 4,554 altogether, including 550 "expert examining surgeons."

The amount of pension awarded is governed by an elaborate classification fixed partly by statute and partly by order of the Commissioner of Pensions.

"Disability equivalent to the ankylosis of a wrist" seems to be taken as a kind of base line, and the pension to an enlisted man for that is 8 dols. a month, or a little over 1s. a day. For the same disability the rates for army officers are for a second lieutenant 15 dols. a month, for a first lieutenant or assistant surgeon 17 dols., for a captain 20 dols., for a major or surgeon 25 dols., and for a lieutenant-colonel or officer of higher rank 30 dols.

The higher rates paid for more serious disabilities range from a maximum of 100 dols. a month for loss of both hands or both feet or of sight, to 55 dols. for the loss of a leg at the hip or an arm at the shoulder so as to prevent the use of an artificial apparatus, 40 dols. for the loss of one hand or one foot or total disability in one hand or one foot. The rate for ankylosis of the shoulder is 12 dols., for ankylosis of the elbow or knee 10 dols. The rates of pension in respect of the more serious injuries have shown a tendency steadily to increase. The rate for loss of both hands or of sight was originally only 25 dols.

It has often been alleged that politicians succeeded in abusing the pension law by means of special legislation in the interest of individuals. It would seem, however, that such abuses as were permitted to occur cannot have seriously affected the grand totals of the number of pensioners and the amount disbursed. Altogether 47,398 special pensions were granted by Acts of Congress, but most of the beneficiaries had been previously pensioned under general laws at lower rates. The number of these special pensions on the roll in 1915 was 21,648, with an annual face value of 6,500,000 dols. out of a total annual disbursement in pensions of 161,000,000 dols.

¹ "Line of duty" is a technical phrase, which is defined in the administration of the pension laws as that relation which a soldier or sailor sustains to the military or naval service of the United States when performing an act connected with any of the possible conditions or requirements of the service, or in the observance of the proper orders of his superiors, not in violation of the army or navy regulations.

THE WAR.

BEDS AND STRETCHERS.

(From a Correspondent in Northern France.)

THE BRADFORD FRAME.

THE Bradford frame mentioned several times with approval at the meeting at the Australian Hospital reported in the *BRITISH MEDICAL JOURNAL* of March 11th, p. 392, is a new introduction over here, but a familiar appliance in certain parts of the United States. It seems to have been in use in Boston for some twenty-five years, and bears the name of the medical man who devised it.

It is a kind of cross between a stretcher and a section mattress, resembling the former because a patient can

FIG. 1.—Bradford Frame.

easily be carried about on it, and the latter because he can lie on it for an unlimited period, any portion of his body being meantime accessible without disturbance of the rest.

Its construction is simple (Fig. 1): four pieces of iron piping about $\frac{3}{4}$ in. in diameter are clipped together by angle irons into an oblong frame, which is filled in by two strips of strong brown canvas. These strips pass over the lateral irons and round to the back, where they are tautened in the middle line by whipcord laces passed through brass eyelets. The whole apparatus weighs about 22 lb.; its dimensions when built for adult use are 76 in. long by 20 in. wide.

So far the description only suggests a stretcher devoid of handles or ground rests, and built of iron instead of wood; but the differences are of some importance. The lack of handles does not prevent the appliance being used like an ordinary stretcher, since the round corners of the frame afford a firm purchase for the hands of bearers, yet their absence, combined with that of ground rests, fits the appliance to be placed on a bedstead or the top of a mattress. Used thus it does not interfere with the comfort of the patient, yet enables him to be lifted off the bed and carried elsewhere at a moment's notice. The strips of canvas do not fill in the frame completely; there is a gap of some 9 in. between the lower edge of the one and the upper edge of the other. This gap occurs about the level of the patient's nates, so that by raising one end or the other of the frame a bedpan can readily be slipped into the desired position. This is the point which affords an analogy with a section mattress, and the resemblance is heightened by the movability of this gap (thanks to the lacing) and the possibility of making an additional gap by subdivision of either strip at any desired point.

This stretcher bed is regarded by those familiar with it as offering great advantages in dealing with all classes of injury, but especially those of the spine. It is also pointed out that the extension of an upper or lower limb can be secured by fixing it to the foot end and counter-extending by a perineal or shoulder band attached to the head end of the iron frame.

THE BRYAN BED.

Another apparatus mentioned at the meeting which may have been unfamiliar to some readers was the Bryan bed, devised by Captain O. W. G. Bryan, R.A.M.C., and described by him in the *Lancet* of January 1st, 1916. We are indebted to the editor of that journal for permission to reproduce two sketches by which the description was illustrated. The bed, our correspondent points out, affords a means of repeatedly dressing a severely septic compound fracture of the femur close to the hip-joint, and of attending to the nursing requirements of the patient without the degree of immobilization of parts previously obtained being in any way disturbed. It may be described as a bold extension of the Hodgett thigh splint. The latter among other things provides for the thigh a moulded bed formed

out of strips of flannel attached to a rigid wire frame running parallel with the limb but a few inches distant from it; the Bryan bed does much the same for the whole body.

Like the Hodgett, it consists of a series of slings which, if their length is duly adjusted, precisely follow the natural contour of the supported parts. In the Bryan bed the slings are attached not to a wire frame suspended from the ceiling or elsewhere, but to two sloping wooden rails standing side by side on their own feet at a distance of about 3 ft. apart (Fig. 2). These rails are kept

FIG. 2.—Bryan Bed, showing the flannel bands attached by chains to the wooden frame.

together by three bars, of which the two at the foot end are prolonged laterally so as to supply *points d'appui* for an extension pulley. This acts through two stirrups—one attached to the thigh, one to the leg—but only one weight is required to exercise traction on both of them because the pulley attached to the upper or thigh stirrup passes through a roller on the lower or leg stirrup. As the slope of the rails is downwards towards the head, the slope of the patient's body supplies the necessary counter extension.

FIG. 3.—Five-fold flannel bands, with rings at the corners and hooks and eyes at the sides (Bryan Bed).

The supporting bands of slings are made of fourfold strips of flannel (Fig. 3) attached to one another by hooks and eyes and to the rails by curtain rings and short lengths of steel chain; so by using one link or another the slings can be precisely adjusted to the patient's body and limbs. Similarly, any one of them can be removed altogether when it is desired to gain access to the overlying part or to release it from pressure. A folded blanket is also slung from the rails, and with the addition of any superimposed blankets can be brought close up to the patient's body so as to keep him warm, or be lowered a few inches so as to provide a support for any nursing utensil or dressing receptacle that may be in use. The wooden framework is sufficiently solid to allow of the whole apparatus—including the patient—being moved from one place in the ward to another if required.

There are many other ingenious points about this appliance which seem to be found comfortable by patients, and certainly meets the direct aim in view. It does not of course render the patient transportable, and though it is not really as complicated an appliance as the description of it might perhaps suggest, full advantage of the possibilities that it offers is not likely to be secured by a surgeon or nurse unendowed with a natural aptitude for mechanics.

[A device designed on the same or a very nearly similar principle for keeping up traction on the soft parts of an amputation stump is described by Captain Bryan in our columns this week (p. 480).]

STRETCHERS.

The wheeled stretcher-bearer mentioned by a battalion medical officer was probably the regulation pattern for

appliances of this order—a couple of rubber-tired steel-spoked bicycle wheels joined by an axle fitted with double elliptic springs on which rests a seating of suitable dimensions for a regulation stretcher. There are also hinged legs which keep the seating level and the wheels from rolling when the carrier is not being held.

But it is not the only pattern in use. The R.A.M.C. has never lacked men with an instinct for mechanics, and such men now are especially common. This is a mechanical age, and among those who have joined the R.A.M.C. for the duration of the war or belong to its territorial units are not a few men who have served their time in "shops" of a more or less engineering order.

The idea of saving labour by providing a hand-pushed stretcher carrier is in itself quite old. The hand-carts so common in Northern Europe seem to have been used largely by Larrey in dealing with the wounded in some of the later Napoleonic campaigns, and stretcher carriers—as distinct from wheeled stretchers, and of a kind closely allied to those used in the army—are to be seen in some civil hospitals built in separate blocks. But in war they have their limitations. They are not fit for work on really rough ground; they are not easy to carry about from place to place ready for instant use; and unless their supports come automatically into action when required, a patient may be thrown off the stretcher should the orderly who is pushing the vehicle stumble badly or fall. Attempts have been made, with more or less success, to eliminate the second drawback by hinging the axle so as to allow of several carriers being placed inside an ambulance, and the third can be lessened by telling off two orderlies to each carrier. Still, even if they were free from all drawbacks, their use would often be superfluous. In several parts of the front the trolley lines laid by the engineers to facilitate the bringing up of supplies can be used equally well for sending back the wounded.

But it is very much less in the direction of stretcher carriers than of stretchers themselves that activity of thought is manifest in front-line areas. As a general utility appliance the regulation stretcher would be hard to beat, but it was designed and perfected when no one dreamed of a war mainly consisting of trench fighting. It can be lowered into a trench and used to lift a wounded man out over the back parapet or parados, but for moving him about inside the trench it is almost useless. It is true that it can usually be got along a communication trench, but between that trench and the fire trenches and in the latter there are corners that cannot be negotiated by anything the length of a stretcher. The difficulty is easy to realize when it is remembered that the usual outline of a trench is very much that of a series of capital U's standing at varying distances apart but united by lines at their tops.

The attempts that have been made to meet the difficulty vary a good deal, but the resulting stretchers fall, roughly speaking, into two groups. In the one the stretcher is no longer a stretcher, but a kind of carrying chair; in the other it is a very narrow vehicle something like a flat-topped wheelbarrow, the handle end of which can be raised into the air. The patient does not fall off because half way down is a kind of saddle or perineal crutch, and at the upper end a shoulder strap. Some of these appliances have obtained a certain measure of success, but usually this has been quite local. The reason is that in point of breadth, depth, and flooring, the trenches, owing to inevitable circumstances, vary all along the line. Consequently, a stretcher contrivance which may just pass muster, or even prove excellent in one series of trenches, may be useless elsewhere.

MEDICAL DISEASES IN THE MEDITERRANEAN WAR AREA.

A SLIM volume of *Memoranda on Some Medical Diseases in the Mediterranean War Area* has been issued by the War Office.¹ It contains short articles on various diseases, and some sanitary notes, including hints on camp sanitation illustrated by drawings and sectional diagrams to scale, designed to furnish information likely to be useful to medical officers who have not had much experience in military sanitation under semi-tropical conditions. Special

attention is directed to flies in connexion with the disposal of excreta; and the necessity for strict discipline is insisted upon. Incidentally it is mentioned that 4,000 flies can emerge from one-sixth of a cubic foot of sewage trench ground, and 500 from a single deposit of human faeces. Directions are given for incineration and for the disposal of refuse and sullage. In discussing the destruction of vermin, an illustration is given of a French modification of the barrel disinfectant, which is stated to be very effective; sulphur fumes are deadly to lice, and in this apparatus fifteen men's costumes can be exposed to them at a time.

The diseases discussed include diarrhoea, dysentery, and hepatic abscess; the various forms of dysentery are discussed at some length with illustrations to assist in the microscopic examination of stools. In speaking of the differential diagnosis in connexion with bacillary dysentery, the observation is made that bilharzial dysentery must be borne in mind, and in the more chronic cases the possibility of tubercle, cancer, and syphilis. Among the other diseases the etiology and treatment of which are described are cerebro-spinal fever, which, it is stated, has occurred at Salonika within recent years, jaundice, oriental sore, and paratyphoid, phlebotomus, relapsing, typhus, and undulant fevers. A characteristic drawing is given of *Phlebotomus papatasi*, and in the section on malaria there is a plate showing the life-cycles of malarial parasites, illustrating the correspondence between the temperature variations and the stages of development.

In a section on insect pests, which are roughly classified into the wingless and the winged, illustrations are given of *Anopheles* and *Stegomyia*, and also of the sandfly, which, it is said, is likely to be met with during the spring and summer in the Balkans. There is also a striking illustration of the larva and pupa of both *Culex* and *Anopheles* shown in characteristic attitudes with their eggs. Several methods of destruction of clothes-lice are mentioned, the first place being given to the use of a suitable sterilizer, the second to sulphur fumigation, and the third to spraying with petrol, paraffin, benzene, or 10 per cent. formalin, or with the steam jet from a kettle. Menthol is mentioned as the chief constituent of powders which have been used with success for sprinkling over the body and clothes. Two prescriptions are given: one of these is menthol gr. 5-10, zinci ox. ad 3j; in the other some pyrethrum and talc are added. An ointment consisting of guaiacol and vaseline is also said to be useful for rubbing into the skin.

There is a note on cholera, of which it is said that though no cases have been reported in the Mediterranean Expeditionary Force, yet with the advent of warm weather and the extension of the campaign to Bulgaria it is more than likely that it may occur in the war area. Of plague it is said that the aggregation of ships in Eastern Mediterranean ports, the movement of Turkish and Russian troops from east to west, and the proximity to Egypt may cause it to make its appearance in the war area. Its etiology, its various types, its diagnosis and prophylaxis, are discussed. A drawing is given of the rat-flea, and also of the black rat, which, as well as the grey rat, suffers from plague. The grey rat is the usual ship rat, but the black rat is said to be the more dangerous as it lives in closer association with man. We commend the introduction of the notes upon these two epidemic diseases, because the book, it is to be expected, will be an indispensable part of the kit of every medical officer serving in the Mediterranean area; and however sanguine our hope that neither disease may attack the British forces, it will be at the moment when a suspicion first arises that the need for an authoritative statement will be most felt, and then it may very well happen that the medical officer concerned may not be able immediately to obtain either clinical or bacteriological consultation.

THE R.A.M.C. AT WORK IN NORTHERN FRANCE.

DR. GRENFELL of Labrador, who has been serving in France with the Harvard surgical unit, contributed to the *Times* last week an article on the work of the R.A.M.C., in which he paid a very high compliment to its organization. He gave a succinct account of the sanitary work, the development of which has been described by our

¹ His Majesty's Stationery Office. To be obtained through any bookseller. Price 1s.

correspondent in Northern France from time to time during the last eighteen months.

When the British took over the trenches west of Ypres, where typhoid was endemic in the villages, our allies, Dr. Grenfell says, had nearly 6,000 cases of the disease. Now, he says:

Typhoid is so small a factor that if a single case occurs anywhere in four armies it is known the same night at head quarters, and next day a rigid local inquiry is held as to the cause. Tetanus, a most terrible and fatal danger of mud associated with wounds, is being met with inoculation so soon after the event that it, too, has become an almost negligible factor in mortality. Trench-feet at first disabled thousands of our soldiers. To-day it is no longer a problem. A batch of such cases is now sent down by the medical officer in the trench with an apology and an explanation, as if it were a misdemeanour. When reference was made at head quarters to a group of 150 cases we had seen a week before coming from a section under deep snow, the Chief of Staff instantly said: "Ah, but that couldn't be helped. There was such heavy 'strafing' for two days there that the men hadn't a chance to change their boots even." It was an act of God, assisted by the Boche. The feet of one of the prisoners brought in at the same time were gangrenous.

Of the arrangements for the prompt treatment of serious wounds he says:

Hospital accommodation is provided, and trained nurses and specially selected surgeons are working, so near the trenches that many abdominal and thoracic wounds are in the operating room in two to three hours—one man was brought in just fifty-five minutes after he had been injured. It is only when one considers how long it takes in London, and also the difficulty of removing any man from the trenches in daylight (so that red crosses on white bands are largely abandoned by stretcher bearers as being rather objects to attract attention of gun-fire than to avoid it), the terrible condition of the shell-torn roads, and the hopeless mud of the sodden country, that the real significance of these magnificent results becomes apparent.

Speaking of the organization for treating wounded, he says that he has heard criticisms on the one hand that operations are entrusted to incompetent hands, and on the other that extravagant salaries are paid for illustrious names.

Neither of these statements (he says) have any truth in them. Unfit surgeons are remorselessly eliminated as soon as recognized, and the army has not paid more than the rank entitles him to for any surgeon. Yet they have permanently in France men whose skill brings them in the comfort of their own homes ten times the money for which they are serving the empire.

To us, the team work of these hospital units, each with its expert in various lines, the pathologists, the x-ray men, the diagnosticians, the therapists, the operating surgeons, and the commanding executive medical officer, suggest an ideal model for the future in civil life. The splendid special dental and eye clinics that have also come into existence are among the best evidences of progress and evolution of the R.A.M.C. in France.

Speaking of wounds of the abdomen, chest, or head, he says that the ideal would be to build a hospital over where the man fell, but adds that at least one field ambulance, so close to the line that the jolting of transport by motor car can be eliminated, has already become a special hospital, although it had to be moved back from its first place to a better shelter a few hundred yards away, because a shell came through the roof. He describes the regimental dressing station as a strongly protected dug-out, and says that the advanced dressing station is often also a dug-out. With reference to the field ambulance head quarters he says that critics forget that nearness and accessibility are far from being synonymous. The clearing stations he describes as economic sieves; rest camps have been added to them, at one of which as many as 80 per cent. are saved altogether the journey to the base and the long absence from their regiment such a journey involves. He mentions the repairing shops, and says that "mobility is preserved by this strict economy, progress is guaranteed by the encouragement which the head quarters staff gives to suggestions, efficiency by the unselfish spirit animating the doctors, nurses, and orderlies."

Dr. Grenfell concludes his article in the following words: "No profession is altogether exempt from self-seekers, disappointed men, incompetent men. Wilfully or otherwise, these men will present false impressions of any service, however noble and efficient it may be, but the British public has no reason to be anxious for their friends in the hands of the R.A.M.C."

GERMAN EXPERIENCES.

MEDICAL PROBLEMS IN WAR.

In a paper read before the Medical Society of Berlin¹ Dr. Goldscheider, consulting physician with a German army, said that the arrangements made in time of peace for the transport of the sick, as distinguished from the wounded, had proved totally inadequate. The underlying principles affecting the removal of the sick were not recognized, and every physician was left to work out a scheme of his own. Many patients suffering from heart disease, nephritis, pleurisy, etc., who succumbed to the hardships of transport could not have been expected to stand even the luxurious travelling of peace time.

Typhoid Fever.

The fate of a patient with typhoid fever was often determined by the decision for or against moving him. When the transport of these cases was inevitable it was advisable to give digitalis, but whenever it was possible, no patient suffering from typhoid fever should be moved before the end of the third week.

If bacteriology was to be of real value in the early diagnosis of typhoid fever, the bacteriologists would have to be stationed much nearer the front than had hitherto usually been the case. In the overwhelming majority of cases the diagnosis of typhoid fever was made independently of bacteriological methods. In clinically atypical cases a bacteriological examination was often indecisive, or was not decisive till the diagnosis could easily be made by other means. The war had shown that the German medical man was insufficiently equipped in the technique of examination and diagnosis, and steps would have to be taken to bridge more effectively the gap between theory and practice. He had found that the subjects of typhoid fever were often treated on the lines of blunderbuss pharmacy. Calomel, opium, quinine, aspirin, pyramidon, digitalis, and caffeine were poured into the patient. Personally he relied exclusively on cardiac remedies and small doses of pyramidon, but he did not approve the systematic administration of large doses of this drug over a period of weeks. The exaggerated claims made on its behalf had led many German physicians to regard it as a specific for typhoid fever. Dyspepsia, nausea, pneumonia, and cardiac weakness were, in his opinion, contraindications. He was not yet sure of the effect of vaccine-therapy, though under certain conditions it was beneficial, and deserved further study. The mortality from typhoid fever varied considerably in the different German armies, owing largely to the varying severity of the disease, the conditions under which transport of the sick was effected, and the facilities for obtaining proper food. The influence of these factors was so great that the mortality statistics in the various armies were no satisfactory guide to the merits of the respective methods of treatment.

Other Infectious Diseases.

At one point on the west front a large crop of cases of Weil's disease developed; its origin was obscure. The conditions under which epidemics and single cases of cerebro-spinal meningitis occurred were also obscure. Trauma and exposure to cold certainly played an important part, and in one case fracture of the base of the skull was followed in a week by symptoms of meningitis, and the meningococcus was found in the throat and cerebro-spinal fluid. Little was seen of febrile articular rheumatism in the winter; but it was relatively frequent in the spring and summer. Most of the patients suffering from muscular and articular rheumatism had already showed signs of these conditions before the war.

Heart Disease.

The frequency of symptoms referable to the heart was surprisingly great, and had increased since the development of trench warfare. They were due to muscular and nervous exhaustion, and of the two the nervous element was the more important. In many patients there were predisposing factors, including faulty development, anaemia, and neurasthenia. Many had previously suffered from nervous palpitation, while others had not been able to stand the change from a sedentary occupation to the

¹ *Berliner klinische Wochenschrift*, November 1st and 8th, 1915.

strenuous life of a soldier. Among the older classes alcohol and early arterio-sclerosis no doubt also played a part. Dr. Goldscheider distinguished three classes of heart cases: (1) Cardiac neurosis associated with general weakness, slight dilatation of the heart, an abnormally low blood pressure, cyanosis, coldness of the limbs, increased frequency of the pulse on slight movement or change of position, and irregular, weak action of the heart; (2) cases in which the symptoms were nervous only and there was no muscular weakness of the heart itself or of the body generally, but often evidence of general nervousness; (3) a large group of cases in which tachycardia was the main or only symptom. The symptoms due to over-exertion were transitory. In all three classes adventitious murmurs and muffling of the first sound were frequently observed.

Dr. Goldscheider deplored the lack of a simple functional test applicable to all these cases; the reaction to graduated exercises was a useful guide, but it often failed to distinguish between the muscular and nervous factors, which, in fact, were often so closely combined that it was wiser to use the term "functional cardiac disturbance" than "nervous or muscular disturbance." The patients in the last two classes often recovered quickly, and even in the second class many were again fit for garrison or even for active service. But some patients were no better after nine months, and the most difficult to cure were the many subjects of neurasthenia in whom cardiac and vasomotor neuroses had existed before the war. The mental factor was of enormous importance, and on this account it was considered unwise to keep the patients in hospitals or sanatoriums for long. For the same reason the slight cases were not sent home, but were employed on light work on the lines of communication. It was also found advisable to distract the patient's attention from his heart, and to treat him only for general exhaustion. When discharged from hospital, many of these patients recovered quickly.

A correct estimate of the condition of the heart of recruits or soldiers required time as well as skill. Modern methods of diagnosis had largely replaced such a simple method as percussion, yet for quick work this was indispensable. The younger generation of medical men had learnt to trust so much to the diagnosis of aneurysm of the aorta by the x rays that they had neglected the simpler tests of sight and touch. The most frequent error was the failure to distinguish between accidental and organic murmurs and arterio-sclerotic myocarditis from cardiac neurosis. In fact, the war had brought into unflattering prominence the ignorance of the medical profession of a group of symptoms with which a very large proportion of the soldiers in the German army were invalided.

BRONCHITIS AND MALINGERING.

During his work as an army physician F. Hamburger (*Der Militärarzt*, August 28th, 1915) often detected soldiers simulating bronchitis. In such cases, when the patient is told to breathe deeply, expiration is laboured and prolonged, and is accompanied by rhonchi and sibil, audible over the whole of the chest. Inspiration, on the other hand, sounds perfectly normal. When, however, the patient is told not to breathe through his mouth but only through his nose, these adventitious sounds become less loud and numerous, although they do not completely disappear. When the patient is told to breathe quietly, but deeply, the respiratory sounds are unaltered, and the patient declares that he cannot possibly breathe in any other way. In these circumstances the physician who is off his guard is apt to diagnose diffuse bronchitis, with or without emphysema. These signs are intentionally produced in the throat and transmitted to the whole of the chest. The laboured and prolonged expiration is due to the voluntary and almost complete closure of the glottis, and the effort required to overcome this obstruction calls into play all the muscles of expiration, and it is to the contraction of these muscles that some of the adventitious sounds heard on expiration must be traced. When the malingerer takes deep breaths these signs are present, and when his breathing is shallow, they cannot be heard. To distinguish between true, dry, diffuse bronchitis and the fictitious bronchitis of the malingerer, the patient is told to stop breathing, but the stethoscope is kept on the chest. When the suspect can no longer hold his breath, but thinks that he is still

expected to do so, his expiration, if he is a malingerer, is perfectly normal. As soon as he is told to breathe deeply again the signs of bronchitis recur. In some cases the patient is guiltless of deliberate malingering, his faulty expiration and consequent simulation of bronchitis being an unconscious act. Owing to the conduction of sounds from the throat and trachea to the chest, catarrh of the throat and trachea facilitates the simulation of true bronchitis.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Prisoners of War.

THE Admiralty announce that the majority of the officers and crew of H.M.S. *Tara*, who were prisoners of war with the forces of the Senussi, on the western frontier of Egypt, were rescued after the recent attack on the Senussi's camp. Ten officers were rescued, including the medical officer of the ship, Surgeon Probationer John D. Arthur, R.N.V.R., and eighty-one men. One engineer lieutenant died in captivity.

ARMY.

Killed in Action.

Captain Ronald Wingrave Duncan, R.A.M.C., was reported as killed in Mesopotamia, in the casualty list published on March 23rd. He was educated in the Medical School of the Royal College of Surgeons, Edinburgh, took the L.D.S. of that college in 1906, and the Scottish triple qualification in 1907. He received a temporary commission as lieutenant on November 24th, 1914, and was promoted to captain on completion of a year's service. He was attached to the second battalion of the Leicestershire Regiment.

Assistant Surgeon Arthur Charles Marchant, Bengal Subordinate Medical Department, was reported as killed in East Africa, in the casualty list published on March 23rd. He was born on November 9th, 1885, attained warrant rank on March 4th, 1907, and was promoted to the third class on March 4th, 1912. Before the war he was serving at Magadi, in British East Africa.

We regretted to announce last week the death of Captain John Wilson, R.A.M.C. In the casualty list he was described as lieutenant, but we understand that he had been promoted to captain. We are informed that the Commanding Officer in communicating the sad news to the relatives wrote:

A message came to our medical aid post that several men were wounded in our centre trench. Captain Wilson at once volunteered to go to their assistance, although it was necessary to cross absolutely open ground swept by the fire of the hostile trenches to do so; owing to heavy shell fire all our wires were broken. However, he reached the trench, bandaged up those who required it most, and was on his way back to the shelter of the quarries, when the Germans in the front fire trench opened fire on him and a bullet struck him just about the heart. I think his death was almost painless, and it was all over in a few minutes. Captain Wilson by his energy and devotion to duty had earned the appreciation of every officer and man in the battalion; it is only ten days since I had the pleasure of recommending him for the Military Cross. He did not know what fear was, and was ready at any moment of the day or night to turn out and give assistance to the sick or wounded.

Wounded.

Lieutenant-Colonel E. A. Wraith, R.A.M.C. (T.F.), France.
Captain G. B. Ferguson, R.A.M.C. (temporary), France.
Lieutenant J. P. Musson, R.A.M.C. (temporary), France.

Died on Service.

Captain George Flett Barr, R.A.M.C., died recently in France. He was the eldest son of the late James Barr, of Thornley, Park Terrace, Paisley, was educated at Glasgow University, where he took the degrees of M.B. and Ch.B. in 1914. He received a temporary commission as lieutenant on January 22nd, 1915, and was promoted to captain on completion of a year's service.

Colonel James Harper, R.A.M.C. (T.F.), died at 25, Rosary Gardens, South Kensington, on March 25th, aged 58. He was educated at St. Bartholomew's Hospital, where he was Brackenbury scholar in surgery in 1881, and took the diploma of M.R.C.S. and the degree of M.B. Lond. with honours in obstetric medicine in 1881. He graduated M.D. in 1883. He was house-surgeon at St. Bartholomew's, house-physician at the Royal Hospital for Diseases of the

Chest, and resident medical officer and anaesthetist of the Chelsea Hospital for Women. He practised for many years in South Kensington. He was Assistant Director of Medical Services of the 1st London Division (T.F.), a member of the City of London Territorial Force Association, Esquire of the Order of St. John of Jerusalem, a member of the Order of Mercy, and a Fellow of the Royal Society of Medicine. He also held the Territorial Decoration.

Captain Robert Francis Hebbert, I.M.S., medical officer of the 107th Pioneers, died in Mesopotamia of relapsing fever on March 19th, aged 33. He was born on March 7th, 1883, the only son of the late Francis H. Hebbert, Indian Civil Service, and was educated at St. Thomas's, taking the M.R.C.S. and L.R.C.P. Lond. in 1906. He entered the army as lieutenant on September 1st, 1906, and was promoted to captain on October 4th, 1909.

DEATHS AMONG SONS OF MEDICAL MEN.

Birdwood, Herbert Frederick, Lieutenant 20th Battalion London Regiment, only son of Dr. Roger A. Birdwood, late medical superintendent Park Hospital, Hither Green, London, S.E., killed in France in an air fight over Valenciennes on March 2nd, aged 22. He was educated at the City of London School, and in 1913 entered Peterhouse College, Cambridge, where he was reading law. He took a commission in the 20th (Blackheath and Woolwich) Battalion of the London Regiment on August 26th, 1914; went to the front in March, 1915; was in the battle of Loos last September, and joined the Royal Flying Corps in December.

Captain John Arthur Graham, 7th Battalion Lincolnshire Regiment, youngest son of the late Brigade-Surgeon H. W. Graham, I.M.S., killed in France on March 20th, aged 40. He was educated at the United Service College, Westward Ho, and at Heidelberg, and was a planter in Coorg, South India. He served as a trooper in Lumsden's Horse in the South African war, gaining the Distinguished Conduct Medal and the Queen's medal with three clasps. He was for many years a member of the Coorg and Mysore Rifles (Volunteers), in which he became second lieutenant on March 6th, 1906, and lieutenant on May 1st, 1907, and held the Long Service Decoration. Coming to England for the war, he got a commission in the Lincoln on April 1st, 1915; went to France in July; was mentioned in dispatches on January 1st, 1916; and received the Military Cross on January 15th.

Morris, Colin Dwight, Second Lieutenant 9th Battalion Royal Fusiliers, only son of Dr. Dwight Morris of Parkside, Feltham, Middlesex, killed in France, on March 14th, aged 27.

Smith, Gilbert Keppel, Second Lieutenant 5th Reserve Battalion Middlesex Regiment, younger son of Dr. Harry Smith of Paddock House, Chatham, killed in France on March 13th, aged 25. His commission was dated March 20th, 1915.

MEDICAL STUDENT.

Goodfellow, E. H., Lieutenant Royal Field Artillery, killed in France on March 8th. He was born and educated in New Zealand, and entered Edinburgh University as a medical student in 1913, aged 21. In his first year he gained five class medals and a Vans Dunlop scholarship. On the outbreak of the war he enlisted in the R.A.M.C., in which he became corporal. He got a commission in the Royal Field Artillery on December 8th, 1914; went to France in February, 1915; was promoted lieutenant last autumn, and was wounded in September.

NURSES.

Dame Lucy Innes Branfoot died at No. 8 General Hospital, Rouen, on March 16th, aged 52. She was the widow of the late Surgeon-General Sir Arthur Branfoot, K.C.I.E., of the Madras Medical Service, President of the India Office Medical Board from 1903 to 1911.

Miss Jeanie Glasford Dalton, Queen Alexandra's Imperial Military Nursing Service, died at the Royal Herbert Hospital, Woolwich, on March 20th. She was the daughter of the late Joseph J. Dalton, of Kamer, Kyles of Bute.

Correction.—In recording the death of Lieutenant Neil Murphy Gavin last week his surname was accidentally misplaced.

NOTES.

AUSTRO-HUNGARIAN CASUALTIES.

The *Morning Post* recently published in a letter from its correspondent in Budapest some statistics obtained from a Hungarian statistician showing that neither Russia nor Germany has lost so many men as Austria-Hungary during the war. The figures are founded on the 320 official lists of casualties, the reports of unit commanders, monthly reports of hospitals, and other documents. It is stated that the losses during the first year of the war amounted to over 3,000,000, not including 200,000 who died of disease. It is also mentioned that the figures include the wounded who have returned to the front, in some cases two and three times; and, further, that the number of wounded can be discounted by nearly 60 per cent., as the cases of total disablement were no more than

15 per cent., while 20 to 25 per cent. who were unfit for service were fit for light or civilian duties. The figures for the three main fronts come down to February 15th or 1st, 1916. Certain casualties in Belgium, where some Hungarian Hussar and artillery regiments served in 1914, are added.

FRENCH WOUNDED FROM VERDUN.

We understand that the British Red Cross sent some fifty ambulance cars to assist in the evacuation of the wounded from the Verdun district. This convoy supplements the unit of twenty-five cars which has been working with the French troops for a year or more. When the German attacks on Verdun began the French found it necessary to transfer the wounded from the hospital to the cellars of the Archbishop's house. Later on they were all moved to Bas le Duc and hospitals further in the rear. The manner in which the evacuation was carried out has been commended in dispatches.

MEDICAL OFFICERS WANTED.

3/2nd East Anglian Field Ambulance.

Medical officer required for this unit, possibly going overseas. Pay and allowances as in regulars. Applications to the Officer Commanding, Halton Park, Tring.

2/1st Highland Mounted Brigade Field Ambulance.

Three medical officers are required to complete establishment of the 2/1st H.M.B. Field Ambulance. Also regimental medical officer for the 2/2nd Lovat Scouts. Applications to Major Mowat, Officer Commanding, 49, Northgate, Beccles, Suffolk.

2/1st North Midland Field Ambulance.

Two or three medical officers are required for this unit to complete establishment for service overseas. Apply Lieutenant-Colonel Dawson, Officer Commanding, Harpenden.

Scotland.

A CONSCIENTIOUS objector of the most pronounced kind was disclosed at a meeting at Oban of the tribunal for the Lorn district in the person of the assistant county medical officer and tuberculosis medical officer. According to a report quoted from the *Oban Times* in the *Edinburgh Evening News* the applicant, believing war to be morally wrong and indefensible, was determined to have absolutely nothing to do with it, either as a combatant or non-combatant, and was unwilling to serve in the R.A.M.C. The tribunal refused the application.

CRIPPLED AND MAIMED SOLDIERS AND SAILORS.

A meeting of the committee of the hospital proposed to be established in the West of Scotland for soldiers and sailors who have lost limbs in the war was held in the City Chambers, Glasgow, on March 23rd. The Lord Provost said that the arrangement mentioned in the *Journal* of March 11th (p. 395) had been confirmed by the military authorities. The hospital will be quite independent of the Queen Mary Auxiliary Hospital at Roehampton, and will receive the same recognition and privileges from the military authorities. It will be available for all Scottish cases sent to it by the authorities, and the committee is making arrangements for an adequate supply of artificial limbs to be manufactured in Scotland. A suitable house in the

vicinity of Glasgow has been secured. Several substantial contributions towards the fund for the equipment of the hospital have been received, including two of £1,000 each.

NEONATAL MORTALITY IN EDINBURGH.

On March 25th Dr. J. W. Ballantyne gave an address on neonatal mortality to the voluntary health visitors in the Council Chambers, Edinburgh. He first contrasted the health conditions of Edinburgh in 1913 and in 1915. The marriages in 1915 had risen by about a thousand, but various causes had doubtless been at work, and no deductions could safely be made. On the other hand, the number of births in 1915 had decreased by about 400, bringing the birth-rate down to the unprecedented level of 17.8; it was a dangerous level, too, for the number of deaths had risen by about 800, giving a death-rate of 16.4. The natural increase of the population in the year 1915, therefore, was only 432, and since the deaths of Edinburgh soldiers at the war were not included, it probably meant that there was no increase at all in the number of persons in the city. The increase in the death-rate, further, was not due, as so often in the past, to a sudden zymotic rise in childhood, but seemed to affect all ages and to have many causes. At the same time the infantile mortality had risen, for 774 babies died in the first year of life in 1915 (an infantile rate of 132 per 1,000), as against 631 in 1913 (101 per 1,000). It was a striking fact that one-seventh of all the deaths which had occurred had been in the first year of life. Just as the first year's deaths were more numerous than those of any succeeding year, so those of the first month of that year were more numerous than those of any succeeding month, and those of the first week than of any succeeding week. The deaths in the first month constituted a third of those of the entire year (257 out of 774). Dr. Ballantyne thought that deaths at this period ought to be considered by themselves in all vital statistics, under the name of the neonatal death-rate. If the neonatal rate had persisted in Edinburgh during the whole of the first year of life there would have been in 1915 not 774 deaths but 3,086, and if the rate in the first week (when 155 perished) had been continued in the other fifty-one weeks, the total infantile deaths for the year would have been 8,060 instead of 774. To look at the matter from the opposite side. If the deaths in the first month had been at the same rate as in the other months, not 257 but only 47 lives would have been lost in that first month, whilst if the rate in the first week had been as the average of the remaining weeks only 12 instead of 155 would have died in that week. The neonatal deaths, therefore, represented death's most successful "thrust" against young life; and the conditions under the war seemed to have made this thrust more successful, for if the 1913 rate had been maintained in 1915 a smaller number than 257 would have been lost. It had at the same time to be recognized that the war conditions had not apparently so marked an effect upon the deaths in the first as upon those in the later months.

The lesson to be learnt was that the health visitors ought to concentrate their attention specially upon the first month of life. They need not, however, as a rule, pay much attention to the first ten days, for during that time the doctor or midwife was in attendance, and presumably was watching over the young life; but after the doctor or midwife ceased attending—namely, in the last two-thirds of the first month—their help and advice would be most helpful in checking the fatalities among the babies. The Royal Maternity Hospital was trying to counteract some of the dangers by its weekly baby clinics for the children of women who had been confined in connexion with the indoor and outdoor departments, but there were still many neonatal lives in Edinburgh to be watched over and reported upon. Further, the health visitors ought to direct their visits chiefly to those parts of the city in which the neonatal death-rate was highest. There should be in the plan of campaign two concentrations therefore—one as to age and the other as to locality.

When the causes of the neonatal deaths were scrutinized and classified it became clear that by far the larger number were in action before birth. Above 60 per cent. were either wholly or partly antenatal in origin; indeed, careful analysis, with all the facts in view, would probably raise the percentage to 70. The obvious lesson was that no care would be sufficient to meet entirely the neonatal risks which did not take cognizance of the mother's health

in her pregnancy. In order to conduct a successful neonatal campaign, the visitors would require to begin with the expectant mothers.

Correspondence.

THE SOLDIER'S HEART AND THE STRAINED HEART.

SIR,—In a letter in your columns on March 11th, p. 396, it is suggested that all cases of "irritable heart" among soldiers may possibly be classified under "tobacco heart" or the "strained heart" due to athletics in boyhood.

That all cases are not due to these causes is shown, I think, by the frequent occurrence of "irritable heart" among the Indian soldiers who have been in hospital in this country. Athletics, if practised at all by Indians in their boyhood, are not carried to the point of strain by the rural classes from which soldiers are drawn, while the use of tobacco in any form is forbidden by their religion to the Sikhs, who suffered in as great a proportion from "irritable heart" as the other races composing the Indian army.—I am, etc.,

R. D. MACGREGOR,
Captain I.M.S. (ret.).

London, W., March 14th.

THE PHYSICS OF A SURGICAL DRESSING.

SIR,—I cannot agree with the objections made to the use of wet dressings with oil-silk. If the gauze in contact with the septic wound is kept moist it absorbs a great deal of pus, which is partly disinfected by the antiseptic in the gauze, whereas with a dry dressing a little is absorbed and cakes, forming a natural impermeable covering, the wound itself being a perfect well of pus. In dealing with acute abscesses a wet dressing with oil-silk tends largely to prevent a secondary infection—a very important point.

Recently I have been using dilute Dakin's solution for treating septic wounds—cyanide gauze saturated with the solution and covered with jaconet. The results so far have been quite satisfactory.—I am, etc.,

OLIVER CARLYLE, F.R.C.S. Edin.,
Lieutenant R.A.M.C.

France, March 8th.

METRIC PRESCRIBING.

SIR,—There can be no disputing the fact that the metric system has come to stay, and as it has been adopted throughout the latest edition of the *British Pharmacopoeia*, the sooner we give our attention to it the better, for that we shall have to do so sooner or later is inevitable. Some practitioners hesitate to put the new system into practice in prescribing, labouring under the impression that it would require a great deal of calculation, and so waste time. But this is a mistake. By the following mode of proceeding very little, if any, calculation is required. Say $7\frac{1}{2}$ grains is the dose we wish to give; write it down as 7.50 grams, and we at once have sixteen doses (the gram being taken at its approximate equivalent), and we substitute metric for old measures at one stroke. The same with minims, bringing them to "mils" (or more correctly "millis"). We can then proceed to divide the amount, or multiply it, to any number of doses we wish to prescribe, and so adapt them to the sizes of bottles as at present manufactured. When the time arrives that metric bottles are made, we shall be as familiar with the new as with the old system. Where fractions or submultiples are concerned—as in pills—it necessitates greater exactitude. If the dose should happen to be $\frac{1}{4}$ the proceedings may be as above; but if not, I find the easiest way is to divide 0.65 (= one grain) by the denominator, thus: gr. $\frac{1}{4}$ = .013 (13 mg.), gr. $\frac{1}{5}$ = .00108 (108 c.mg.), and so on. And to prescribe ten pills we simply move the decimal point one place to the right, thus: .13 and .0108.

Metric measures or rules for sight-testing purposes may be obtained from the Decimal Association, Finsbury Court, Finsbury Pavement, E.C. It may interest your readers to know that this association is now engaged in preparing a scheme for the decimalization of our monetary system, taking the florin as the unit, and introducing two new coins of nickel with scalloped edges, of the value of 5 and 10 cents.—I am, etc.,

London, S.W., March 18th.

W. W. HARDWICKE, M.D.

MATERNITY AND CHILD WELFARE.

SIR.—On reading the commentary on the official scheme I was struck by the expression, "Educating the mothers"; what about educating the fathers? As a general medical practitioner I have found it very uphill work to get certain husbands to believe that the wife required rest. The primiparae, as a healthy class, do not require much care, whereas the multipara is beginning to feel that life is almost too much for her. The legs of some of these women are a disgrace to humanity. One sees them accidentally, and if as a sympathetic creature one advocates rest, the patient says, "It is all very well speaking, doctor; my husband thinks there should never be anything wrong with me."

From my past experience as a busy general practitioner (married and pregnant), attending to all medical duties during the first six months—midwifery cases included, with instrumental interference as well—I hold that to give every pregnant woman three months' freedom from worry and partial rest before her child is born, and three months after (if she nurses the child), would get rid of the weak infants that have no vitality to begin this life.

What a good time the cow and the mare have at this time! Are the mothers and children not of as much importance?

I rejoice in the National Insurance at present, as there is some assurance of rest (free from worry) for the pregnant woman. A patient of mine had been warned by her doctor to delay her marriage as she was too delicate; but at length she did marry. During her pregnancy she was in a very serious state, but with care and several months' rest, instead of chloroform and forceps as I had anticipated she would require, her child was born quite easily after she had been in labour for about eight hours. The baby was a good-sized, healthy child. I am quite sure that even with the best medical interference, *minus* the rest, she would not have lived through it, and certainly would not have brought forth a child such as she did.

Do not spend money on notifications, but let the women be the recipients of it.—I am, etc.,

Portobello, March 8th.

MARGARET W. CAMERON.

Universities and Colleges.

UNIVERSITY OF DURHAM.

The following candidates have been approved at the examination indicated:

THIRD M.B. (*Materia Medica, Pharmacology and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology*).—P. V. Anderson, R. V. Brew, H. J. Dingle, D. Honedan, W. A. Howison, C. G. Irwin, G. M. Kerry, J. K. R. Landells, S. A. Shehid, I. Soliman, H. I. Sterne-Howitt.

UNIVERSITY OF EDINBURGH.

The following candidates have been approved at the examination indicated:

FINAL M.B. AND CH.B.—K. P. Brown, C. A. E. I. Brownlee, *A. J. Caird, B.Sc., Yun Yin Chan, F. W. Clark, G. T. I. Clarke, A. Cleland, J. A. Crawford, R. C. Crawford, H. J. Davidson, J. Dickson, *A. V. Dill, Th. Doe, W. H. Ferguson, G. H. Fraser, L. B. Gadinil, J. A. C. Guy, C. Harris, C. E. Hill, J. M. Johnstone, E. B. Kelley, J. B. P. McLaren, J. Manuel, G. Morris, M. S. N. Panikkar, *D. H. Paterson, P. A. Rostad, J. J. Shannon, N. H. Smith, D. R. Thomas, A. F. de Waal, Gladys Ward, J. M. Watt, H. D. Wright.

* With distinction.

UNIVERSITY OF ST. ANDREWS.

The following candidates have been approved at the examinations indicated:

SECOND M.B., CH.B. (*Physiology*).—J. M. Craig, C. B. Dyson, Janet M. MacMillan, Florence B. Mason, Phyllis Montford, W. G. Robertson, Gladys J. C. Russell, J. N. D. Smith, J. C. McGregor, N. MacVicar.

THIRD M.B., CH.B. (*Pathology*).—J. MacD. Clark, J. C. Coutts, J. Ferguson, J. C. McGregor, J. K. T. Mills, J. M. Orkney, G. R. Ross, G. R. Tadhope.

FIRST D.P.H. (*Bacteriology*).—E. E. Cassidy, D. M. McGillivray.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved at the examinations indicated:

SURGERY.—*J. M. Dwyer, *J. Fox-Russell, *H. M. Gray, *R. Milne. MEDICINE.—*M. Dwyer, *E. N. Glover, *R. Milne.

FORENSIC MEDICINE.—C. G. Bunn, M. Dwyer, E. N. Glover, R. Milne, R. H. Pottersson, J. M. Wall.

MIDWIFERY.—R. Milne, L. F. Pain, A. E. Pollitt.

* Section I.

† Section II.

The diploma of the society has been granted to the following: J. Fox-Russell, H. M. Gray, and R. Milne.

Obituary.

STAMFORD FELCE, M.R.C.P. EDIN., M.R.C.S. ENG.

THIS veteran in the profession died at his residence at Burgess Hill, Sussex, on March 20th, in his 81st year. Dr. Felce was born in Huntingdon on October 7th, 1835, and received his medical education at St. Mary's Hospital. He took the diploma of M.R.C.S. Eng. in 1859, in which year he became resident medical officer at St. Mary's. In the following year he took the diploma of M.R.C.P. Edin. After holding the appointment of resident house-surgeon to the Western General Dispensary he commenced private practice in Launceston at the end of 1860, and became a member of the Cornwall Branch of the British Medical Association. In 1868 Dr. Felce returned to London, and became a member of the Metropolitan Counties Branch. He took up his residence in Paddington, where he remained until his retirement from practice in 1903. Members of the Association who were present at the annual meeting in 1896 held at Carlisle will remember how Mr. Lawson Tait suggested that a committee of inquiry should be appointed for the purpose of reporting on certain desired reforms. Dr. Felce took part in the discussion, and was made in October, 1896, a member of the Committee on the Constitution of the Association, of which the chairman was Dr. Robert Saundby, the treasurer Dr. C. Parsons, the other members, besides Dr. Felce, being Lord Ilkeston, Mr. Waid Cousins, Dr. Leonard Sedgwick, Dr. Markham Skerritt, Mr. Lawson Tait, Mr. Walter Whitehead, and Dr. Woodcock. Dr. Felce was very active in discharging other public duties connected with the profession. He was for many years honorary secretary of the Royal Medical Benevolent Fund, and became vice-president of that institution, as well as of St. Mary's Hospital and Epsom College. He was president of the Medical Defence Union, honorary secretary and treasurer to the Charles Bailey Charity (1890-1912), and member and chairman of the Paddington Board of Guardians. He was for many years a member of the Metropolitan Asylums Board, chairman of its North-Western Hospital (1885-1896), and chairman of the Darent Asylum. Dr. Felce was instrumental in bringing about the building of St. Peter's Church, Paddington, of which he was a trustee and for seventeen years vicar's churchwarden. At the age of 71 he visited a son in India and at the age of 76 underwent amputation of the leg. Dr. Stamford Felce married in 1861, and his widow, three sons, and four daughters all survive him.

MARY CHARLOTTE MURDOCH, L.R.C.P.,

L.R.C.S. EDIN., L.F.P.S. GLASG.

SENIOR PHYSICIAN, VICTORIA HOSPITAL FOR SICK CHILDREN, HULL.

DR. MURDOCH, the first woman to practise medicine in Hull, died at the age of 50, on March 20th, of an acute attack of influenza. She was the youngest daughter of Mr. William Murdoch, solicitor, of Elgin, and was educated at Edinburgh, Lausanne, and London. She studied at the London School of Medicine for Women, and was in 1892 curator of its museum. She took the Scottish triple diplomas, and in 1893 was appointed house-surgeon to the Victoria Hospital for Children, Hull. An attack of an illness, from which she had suffered when a student and which often recurred throughout her working life, brought about her resignation, but on convalescence she was selected medical officer to the North-East London Fever Hospital, South Tottenham. Dr. Murdoch often spoke in after-life of how much she owed to the chief medical officer, Dr. Birdwood, from whom she learnt much as to diagnosis and prognosis in acute infectious diseases, for skill in which she became well known. Meanwhile she was frequently urged to return to Hull, and in 1894 she set up in private practice there—a venture which met with immediate

success. In 1894 she was appointed honorary assistant physician and in 1897 senior physician to the Victoria Hospital.

Dr. Murdoch joined the British Medical Association in 1894, and was vice-president of the East York and North Lincoln Branch in 1909. She was also vice-president of the Association of Registered Medical Women. Dr. Murdoch took much interest in national, political, and philanthropic work of various kinds. She founded a local branch of the National Union of Women Suffrage Societies, of which she became president, only retiring when she undertook the presidency of the Hull branch of the National Union of Women Workers. She attended meetings of the International Council of Women at Toronto, the Hague, and Rome, at each of which she was one of the principal speakers. Dr. Murdoch, who was a vivacious and arresting speaker, took a lead in the purity campaign, and was an honorary medical officer of the Central Nursing Division of the St. John Ambulance, lecturing to the police force and to the North-Eastern railway men. In short, Dr. Murdoch was a very vigorous professional woman. Unfortunately she overtaxed her strength, and was greatly distressed because only a few weeks ago the infants' ward at the Victoria Hospital for Children had to be closed for lack of funds, and she had already, just before her decease, undertaken to raise £250, the sum necessary to reopen it.

A Requiem Mass was celebrated at St. Francis's, Hull, on March 24th, and later in the day thousands of the inhabitants of the city followed the funeral procession first to All Saints' Church, then to the Crematorium, and later to the deposition of the urn in the Lady Chapel of All Saints.

ALDERMAN THOMAS UNDERHILL died at his residence in Bromwich on March 10th, just after celebrating his ninety-second birthday. Born in Tipton, Staffordshire, on February 3rd, 1824, the son of a surgeon in that town, he studied medicine at Birmingham, and took the diplomas of M.R.C.S. and L.S.A. in 1845 and that of L.R.C.P. Edin. in 1859. He graduated M.D. St. Andrews in 1871. When his father, Dr. Thomas Underhill, retired from professional work he and his brother William continued the practice in Tipton. In 1873 he went to West Bromwich. He became president of the Birmingham and Midland Branch of the Association and member of the Council of the Birmingham Medical Institute. Dr. Underhill took great interest in public work in West Bromwich; in 1882, when that town secured the charter of incorporation, he was elected one of the first aldermen, and was the second to occupy the office of mayor (1884-5). He was already among the oldest of the county magistrates, and when living at Tipton he was one of the pioneers of the movement for the erection of the Dudley Guest Hospital, and was afterwards honorary surgeon for sixteen years. When he celebrated his golden wedding some years ago a cheque for £1,000 subscribed by his many friends was presented to him. The funeral took place at Tipton Parish Church on March 16th.

DR. ROBERT JAMES HORN of St. Faith's, Norwich, died on March 22nd rather suddenly, although some of his friends and professional brethren were aware that for many years past he had not enjoyed perfect health. Dr. Horn studied medicine at the Middlesex Hospital, and took the diplomas of L.R.C.P. Edin. and L.F.P.S. Glasg. in 1881. Seven years later he settled at St. Faith's, Norwich. In addition to an extensive private practice, he held several Poor Law appointments, and for some years was chairman of the parish council, where he distinguished himself by actively opposing unnecessary expenditure. He was also a searching and painstaking school manager. Dr. D. G. Thomson of the Norfolk County Asylum writes: "Ever since the reconstitution of the British Medical Association Dr. Horn has been my most trusty lieutenant—in the early days especially. He would never take office in the Division as president or secretary owing to his health, but he was on all committees, represented the Division on the Branch Council, and was a member of the Panel and Local Medical Committees for Norfolk; his death is a great loss to the Division."

COLONEL RICHARD PATRICK FERGUSON, R.A.M.C.(ret.), died at Southsea on March 10th. He was born on

March 13th, 1839, educated in the school of the Royal College of Surgeons, Ireland, and took the diplomas of L.R.C.S. and L.R.C.P. Edin. in 1860. Entering the army as assistant surgeon on March 1st, 1862, he became surgeon on March 1st, 1873, surgeon-major on March 1st, 1874, and surgeon-colonel on September 6th, 1892, retiring on March 13th, 1899. He served in the Bhutan war of 1864-65, and was present at the assault and capture of Bala, receiving the Indian frontier medal with a clasp; in the Afghan war of 1878-79; in the second division with the Peshawar Valley field force, medal; and in Egypt in 1882, medal and Khedive's bronze star.

DR. WILLIAM LOUIS ROBBAN, president of the American Medical Association, died in Philadelphia on March 8th in his fifty-eighth year. He graduated at Jefferson Medical College, Philadelphia, in 1879, and, after serving in the United States army for two years, he was demonstrator of surgery in the University of Louisiana from 1885 till 1893, and afterwards was professor of surgery in the Medico-Chirurgical College, Philadelphia, and in the Woman's Medical College of Pennsylvania. He was the author of numerous contributions to surgical literature.

DR. LUIS COMENGE, who died recently aged about 60, was head of the health service and director of the municipal laboratory of Barcelona, and did valuable work in epidemics of cholera and bubonic plague in Spain and the Canary Islands. He enjoyed a considerable reputation among his fellow-countrymen as a writer on medical history and antiquities and the social and literary aspects of medicine.

DR. ACHILLES ROSE, of New York, who died on January 10th, aged 76, was born at Ruhla in Thuringia in 1839. After studying at Zurich and Jena he went to the United States, and graduated in medicine at the New York College of Physicians and Surgeons in 1872. He was an accurate scholar who included not only classical, but Byzantine and modern Greek in his range of study. He was well known by his advocacy of modern Greek as the right source of medical terminology whenever no suitable ancient root could be found. He was carried so far by his enthusiasm that he urged the adoption of Greek as the language of medical science; in this, however, he was a voice crying in the wilderness. Dr. Rose had for some years been engaged in the preparation of a new medical lexicon based on those principles. For his work in this field he was elected an honorary member of the Athens Academy of Medicine, and in recognition of his interest in the Greek language and history he received a decoration from the King of the Hellenes. Dr. Rose was the author of several works on modern Greek and medical onomatology; of a book entitled *Napoleon's Campaign in Russia, Anno 1812*, and of other works on the treatment of fever by continuous bathing and other therapeutic subjects.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Rudolf Dohrn, for many years professor of obstetrics at Königsberg and head of the gynaecological clinic of that university, aged 79; Dr. C. Townsend Dade, consulting dermatologist to the Manhattan State Hospital, the Roosevelt Hospital, and other public institutions of New York, aged 56; Dr. Lajos Makara, professor of clinical surgery in the University of Klausenburg, aged 53; Dr. Boleslaw Wicherkiewicz, professor of ophthalmology in the University of Cracow, aged 68; Dr. Alexandre Moutier, of Paris, author of numerous writings on the application of d'Arsonval's discoveries on high-frequency currents in medical practice; Dr. Edmond Heckel, professor in the Medical School of Marseilles, founder and director of the Marseilles Colonial Institute, a corresponding member of the Institute of France, and a member of the Paris Academy of Medicine; Dr. Alzheimer, professor of psychiatry in the University of Breslau, author of many contributions to the pathology of mental diseases, and joint founder with Lewandowsky of the *Zeitschrift für die gesamte Neurologie und Psychiatrie*, aged 52; and Dr. T. Langhans, whose name is associated with the discovery of the giant cell, till recently professor of pathological anatomy at Berne, aged 76.

Medical News.

ON St. Patrick's Day the Irish Medical Schools' and Graduates' Association presented the Arnott gold medal to Captain W. Loughnan, R.A.M.C., of Dublin, for conspicuous gallantry in the field.

COLONEL CHARLES STONHAM, senior surgeon to the Westminster Hospital, left estate of the gross value of £24,865.

THE tenth triennial session of the Congress of American Physicians and Surgeons will be held at Washington on May 9th and 10th under the presidency of Professor W. S. Thayer.

A DISCUSSION on the rationale and practice of chemotherapy will be opened by Mr. J. E. R. MacDonagh in the Section of Dermatology of the Royal Society of Medicine on Thursday, April 13th, at 5 p.m., when a number of leading chemists are expected to be present.

A DENTAL department has been organized at the Angell Memorial Hospital of the Massachusetts Society for the Prevention of Cruelty to Animals at Boston. Treatment is to be provided for animals suffering from defective teeth.

THE publication of a new quarterly periodical entitled *Journal of Cancer Research* is announced. It is the official organ of the American Association for Cancer Research and is edited by Dr. Richard Weil of the Cornell University Medical School.

THE Women's Imperial Health Association, 7, Hanover Square, London, W., has printed a leaflet founded upon the memorandum on measles issued by the Local Government Board. It seeks to impress upon parents the importance of the proper medical treatment of measles in view especially of the complications and after-effects.

THE 150th anniversary of the foundation of the medical school of the University of Pennsylvania was celebrated by a dinner given by the Society of the Alumni of the school on February 4th. The school was founded by Dr. John Morgan in 1765, an event which marks the beginning of medical teaching in the United States.

WE learn from the *Medical Journal of Australia* that in consequence of the failure of attempts to obtain Government help in the furtherance of the scheme, a company has been formed by the members of the Cremation Society of New South Wales for the erection of a crematorium in the neighbourhood of Sydney. Among the provisional directors are the Hon. Dr. J. M. Creed, Dr. Foreman, and Dr. A. L. Kerr.

DR. SIMON FLEXNER was elected president of the American society for experimental pathology for 1916 at a meeting recently held in Boston. The society will hold its next meeting in New York in December next in combination with the other constituent organizations of the federation of American societies for experimental biology.

THE Physiological Society will issue next week the first number of a monthly number, the scope of which is sufficiently indicated by its title—*Physiological Abstracts*. It will contain abstracts of papers on physiology, comparative physiology, and biochemistry. It will be edited by Professor Halliburton, King's College, Strand, W.C., to whom reprints of papers should be sent. It will be published by Messrs. H. K. Lewis and Co., Ltd., 136, Gower Street, W.C., at an annual subscription of 25s., post free.

THE Natural History Museum, South Kensington, is now open to the public in part. The sections open daily are the central hall, containing special exhibits, including the large models of mosquitos, tsetse flies, and the parasites they convey; the north hall containing domesticated animals, and the galleries for birds, mammals, shells, and botany; most of these parts are also open on Sundays. Other galleries are open on alternate days; the reptile and insect galleries on Tuesdays, Thursdays, and Saturdays. On week-days the public is admitted to the parts named at 10 a.m. to 6 p.m. (April to August inclusive); on Sundays the hour of opening is 2 p.m.

THE Local Government Board has issued a circular letter dated March 23rd to boards of guardians setting out methods of applying the general principle adopted, in conjunction with the Army Council, in regard to the payment of compensation in respect of Poor Law institutions wholly, or in part, made use of for military purposes. The Army Council will not pay rent, or make any contribution in respect of existing capital charges, but will reimburse the guardians the whole of their authorized expenditure upon the occupied premises during the period of the military

occupation, including the remuneration of all officers and servants employed in and about those premises.

THE present dearth of chauffeurs, coupled with the fact that 1,500 new motor vehicles are put on the road every month in the United Kingdom, has led the British School of Motoring, Limited, to transfer its instruction premises (formerly at Peckham Rye) to South Kensington. Among the speakers at a luncheon which preceded the formal opening was Sir W. Arbuthnot Lane, who laid stress upon the physical value of motoring as a profession for women. Motoring, with the varying positions it demanded, brought into play muscles which otherwise were often allowed to remain unexercised. He suggested that motoring would go some way towards solving the problem presented by the increase in the numbers of women who must necessarily remain unmarried.

AT the opening of the Italian field university (*Università castrense*) at San Giorgio di Nogaro, some four hundred medical students were present. The Rector (Professor Tusini) explained that its object is to give advanced students actually serving with the army the opportunity of continuing their studies in medicine and surgery. The university has its head quarters in the communal palace, the council chamber being used as a lecture room. There is a theatre for anatomical and surgical work with accommodation for five hundred students and a fully equipped post-mortem room. The teaching installation is completed by a separate building for instruction in mental diseases, and laboratories of bacteriology, stomatology, etc. The students are lodged in barracks.

A. N. RACHMANOW has reported (*Medizinskiye Obosreniye*, 1915, Nos. 1-2) 2,586 cases of abortion observed by him in a lying-in home in Moscow. In comparatively aseptic cases all methods of treatment gave the same good results, with a slight advantage for instrumental interference. Quite different were the results in the infected cases. Those in which the ovum was removed manually suffered least; while those not interfered with suffered more, and most of all those submitted to instrumental treatment. That manual interference, and not expectant treatment, gave the best results appeared to depend not on the fact that the defending granulating surface was undisturbed, and a wide way opened for infection, but was due to the circumstance that with an instrument even the most experienced gynaecologist might leave some infected pieces of membrane behind, as an energetic curettage was always attended by the risk of rupturing the uterus. The author prefers manual treatment because much was learnt by the sense of touch in the finger, and because it rendered necessary greater dilatation, which provided better opportunities for drainage. He therefore recommends not aiming at scientific researches the following rational method of treatment to all persons and institutions: In non-infected cases shorten the process of abortion by operative treatment; in infected cases dilate to the maximum, and remove manually the ovum or its remains. The spoon should be used only when dilatation of the cervix for the admission of a finger is impossible.

THE *Chinese Recorder*, which is the monthly periodical of the American Presbyterian Mission Press, and is published in Shanghai, devoted its issue for November, 1915, to the subject of medical education in China. It contains articles on the Rockefeller Foundation and medical education in China, by Dr. E. W. Merrius; on the China Medical Board, by Mr. Roger S. Green; on union medical work in Canton by Dr. Andrew H. Woods, and in Peking by the President of the Union Medical College, Dr. J. G. Cormack; on medical education in Nanking by Dr. Nathan Worth Brown, in Shanghai by Dr. J. C. McCracken; on the Union Medical College, Tsinanfu, by Dr. H. Balme; and on the Hunan-Yale Medical College as a Co-operative Institution with the Chinese, by F. C. Yen, M.D. These articles do not cover the whole ground, for there are at present 29 medical schools in China, 16 of which are missionary enterprises, 8 belong to the Chinese Government, and 5 are maintained by non-missionary foreigners. The editor, indeed, claims that the schools treated in this part of the *Recorder* are "sufficient to give an all-round view of the general problem of medical education"; but since the C.M.S. work at Hangchow, the enterprise of the U.F. Church of Scotland and of the Irish Presbyterians and Danes at Moukden, and the colleges at Hankow and Foochow are practically unconsidered, it is difficult to accept his assurance in full. One of the problems discussed is the language medium in which instruction is to be given—Chinese or English; but it seems to be more reasonable that a few English-speaking teachers should learn Chinese in order to instruct the many Chinese students than that all the latter should be compelled to learn English that they may understand their teachers.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, Aitology, Westrand, London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, Medisecra, Westrand, London; telephone, 2634, Gerrard. The address of the Irish office of the *British Medical Association* is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

T. A. B. H. has bought a practice, paying one-eighth of the premium down and the rest by quarterly instalments. He inquires whether income tax should be deducted from the quarterly payments.

* If these payments constitute instalments of a pre-determined purchase price, our correspondent has no right to deduct income tax; on the other hand, if the agreement for purchase of the practice provided in terms for payment of a lump sum and of an annuity for a period payable in quarterly amounts, then income tax is deductible. From the particulars furnished by our correspondent the case appears to fall into the former class. Land tax is payable unless it can be shown that it has been "redeemed" by payment of the capitalized value. The authorities usually require production of the redemption certificate as evidence of non-liability. "Exemption" is granted if the total income of the owner does not exceed £160.

LETTERS, NOTES, ETC.

LIEUTENANT T. B. JOBSON, R.A.M.C., War Hospital, Dartford, is anxious to obtain some human bones for use at a training school for R.A.M.C. men.

DR. JEPSON—and in this he supports the view expressed by the Health of Munition Workers Committee—writes to recommend that in every department or section of works where girls are employed there should be a woman head, and that it should be her duty to make a note about each girl under her, and in particular to arrange that they should have periodical periods of rest at the menstrual periods. He considers that lady doctors and women's societies might do even more for their own sex than they are.

LEPROSY AND FISH EATING.

DR. G. ARBOUR STEPHENS (Swansea) writes: James Howells, in one of his *Familiar Letters*, written on April 10th, 1622, from Treve, states: "We are now in North Holland, where I never saw so many, among so few, sick of leprosy; and the reason is, because they commonly eat abundance of fresh fish." According to this letter, Sir Jonathan Hutchinson seems to have been corroborated as early as 1622.

MAGNESIUM SULPHATE LOTION IN CELLULITIS.

DR. ALBERT E. MORISON (Sunderland) writes: Lieutenant S. A. B. Paymaster has drawn attention to the above in the *JOURNAL* of March 11th. His findings corroborate those published by Dr. Tulloch and myself on the treatment of all septic wounds by this salt. The treatment of erysipelas by magnesium sulphate is of very old standing, and is mentioned in several textbooks on surgery published before the dawn of the Listerian era of antiseptic surgery. It was, of course, at that time used empirically; now we know as a result of the researches of Dr. Tulloch that its action is due not only to its hypertonic action on the tissues, but to the power it possesses of inhibiting the growth of streptococci and most of the granulated-negative forms of bacilli found in wounds. I would, however, suggest that the effect of the treatment is very much hastened and more efficacious, and the change of dressings is less frequently required, if a saturated solution of magnesium sulphate with 10 per cent. glycerine is employed. This we have found by numerous experiments gives the best results in septic wounds and infective conditions.

TRACHOMA IN U.S.A.

THE United States Public Health Service has established five hospitals for the treatment of trachoma in the three States of Kentucky, Virginia, and West Virginia. In the past fiscal year 12,000 cases have been treated, most of which have been cured; those in which a cure was not effected were so far

improved as to be made harmless to other people. In addition to the hospital work, doctors and nurses have visited patients at their homes and given instruction as to the means of preventing the development and recurrence of the disease. Surveys were made in sixteen counties in Kentucky, especially among school children. Of 18,016 persons examined, 7 per cent. were found to have trachoma. Similar inspections in certain parts of Arizona, Alabama, and Florida showed that from three to six in every hundred children were affected.

PEPPER IN THE PROPHYLAXIS AND TREATMENT OF FILARIASIS.

MR. T. A. R. AIYAR, L.R.C.P. and S. Edin., L.F.P. and S. Glasg. (Sitiawan, Lower Perak, F.M.S.) writes: All classes of Indians indulge in pepper, and I can hardly imagine even a single class that does not consume it in some form or other. Notwithstanding this, filariasis is not an uncommon affection among them. This malady existed some three decades ago to an alarming extent, chiefly in seaport towns, where the sanitary conditions were very imperfect, and elephantiasis of the scrotum, leg, etc., was quite common. With improved sanitary conditions the disease has been practically stamped out from these towns. Still, in some rural areas *Filaria medinensis* is quite a common parasitic affection, and the sufferers here all partake of pepper. I have had some hundreds of cases of guinea-worms under my care and personal observation. In one case of the worst form of chyluria the sufferer was an Indian, who was ingesting pepper every day as a part of his daily rations. This man eventually died, and necropsy revealed obstructions of the various lymphatic channels with the ova of the mature parasites. I therefore conclude that pepper has no place in the armamentarium of drugs either as a prophylactic or remedial agent in this particular form of ailment.

HERPES OF THE PENIS.

MAJOR M. S. IRANI, I.M.S., writes: I have under treatment for the last six years a very obstinate case of neuralgic herpes of the genitals similar to one described by your correspondent in the *Far East* in the *BRITISH MEDICAL JOURNAL* of January 22nd, 1916. The patient is a well-built young man, aged 37, in good health, of active habits, a total abstainer, a non-smoker, and free from any specific disease or any hereditary taint. The complaint commenced over six years ago in a very insidious manner, the earlier attacks being very mild and very short. The neuralgic attacks came on at irregular intervals, at first once or twice a month but later more frequently, often two or three times a week, apparently without any cause or provocation; they lasted from a couple of hours to twelve, or on some occasions over twenty-four, hours. The patient's attention was first drawn to the condition by the appearance of a small vesicular eruption on the prepuce. The severity of the attacks varied from slight hyperaesthesia or mild burning sensation to very severe neuralgic pains in the following sites—the skin of the scrotum, prepuce, the skin of the upper and inner part of either thigh, right gluteal region, and, on rare occasions, left heel; nerves affected—ilio-inguinal, genito-femoral, anterior cutaneous and medial calcaneal. More than one place was rarely affected simultaneously; the pain commencing in one place shifted to another within a short time, or it remained localized in one spot until it disappeared. The most peculiar feature of the case is that a day or two after the attack leaves the patient a very small crop of herpes appears, always on the prepuce without any regard to the site or sites attacked by neuralgia. It consists of not more than three or four small vesicles on an inflamed hyperaemic base, which ulcerate, producing small round ulcers with clean cut margins. In the earlier stages of the complaint these took two to three weeks to heal but latterly they heal in a week. The eruption is not painful. The attacks of late have become less frequent, there being often an interval of two months, and the severe type is less common. Medicinal treatment has made no difference in the frequency, duration, or severity of the attacks. The patient had met with a riding accident about eighteen months before he noticed this complaint. He was badly shaken but did not sustain any damage to any bones or organs, and was not incapacitated from work for more than three or four days. I should be very grateful if any of your readers would make any suggestions for treatment or give information as to the pathological lesion, and references to literature on the subject.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

PENETRATING WOUNDS OF THE ABDOMEN.

BY

CAPTAIN JOHN FRASER, M.D., M.Ch., F.R.C.S.E.,

R.A.M.C.,

ASSISTANT SURGEON, ROYAL HOSPITAL FOR SICK CHILDREN,
EDINBURGH;

AND

CAPTAIN H. T. BATES, B.A., M.B., CH.B. DUBL.,

R.A.M.C.(T.),

BRITISH EXPEDITIONARY FORCE.

(Report to the Medical Research Committee.)

We have lately had an opportunity of observing the operative results of a number of cases of penetrating wounds of the abdomen. So much debate has centred around the treatment of these cases that we believe it may be of interest to record some of the observations which we have made.

PENETRATING ABDOMINAL WOUNDS CONSIDERED LOCALLY.

WOUNDS OF STOMACH.

We have had a total number of six cases, and they illustrate wounds of almost every possible portion of the stomach.

Morbid Anatomy.

The degree of damage which is sustained depends on two factors—the nature of the projectile, whether shell fragment, bullet, or bomb, and the part of the stomach which is injured. In regard to the first qualification, shell fragments produce almost invariably the most extensive destruction, for combined with the irregularity in their shape there is a high degree of velocity in the speed with which they strike the part. These facts are illustrated both by text and diagram in Case v. Bullets generally behave as they do in other soft tissues, that is with a small entrance wound and a larger wound of exit, but, as will be shown later, the amount of damage produced by a bullet is very closely related to that part of the viscus which is struck—for example, bullet wounds of the pylorus are more extensive than bullet wounds of the body of the stomach. Bomb wounds in their degree occupy a position which is midway between the shell and the bullet wound; the bomb fragment has the irregularity of the shell fragment, but its velocity is comparatively small. The region of the stomach which is injured is all-important, and these remarks apply to bullet wounds, as shell and bomb wounds do not appear to be so much influenced by position. Bullet wounds in the centre of the body of the stomach have a comparatively small entrance and a slightly larger exit wound. A bullet wound in the region of the pylorus has a relatively small entrance wound, but the exit wound is usually large and pouting. The greater degree of severity would appear to depend on the fact that the projectile passes through the thicker musculature in the neighbourhood of the pylorus (see Case vi).

Bullet wounds involving the greater or lesser curvature are always extensive; the lines of force are such that accompanying the actual wound there is extensive splitting and tearing of the musculature of the stomach wall (see Case v).

The haemorrhage is not severe unless the wound has actually involved one of the larger vessels (coronary or gastro-epiploic), and in this respect stomach wounds differ from wounds of small intestine.

There is usually haemorrhagic infiltration of the peritoneal and muscular coats, and it is important to notice that there are points of tissue separation and actual tissue necrosis for a considerable distance around the wound.

Clinical Features.

Wounds of the stomach demonstrate the clinical features which one associates with wounds of the hollow viscera of the abdomen generally—there is pain, sickness, collapse, rigidity of the abdominal wall, with tenderness on pressure; but, in addition to these general features, there are certain distinctive signs. Sickness is usually more pronounced than in wounds of the other abdominal viscera, and in the vomited matter it is rarely that one fails to

find the presence of blood. The degree of collapse is less marked than that found in intestinal injuries, but, whether or not this is related to the comparatively smaller amount of haemorrhage one cannot say.

It is interesting to note that, while the pulse and respiration rates are both increased, the respiration-rate has proportionately increased more rapidly than the pulse-rate. The degree and the variety of the clinical features are influenced considerably by the situation of the lesion. Pain would appear to be more intense when the cardiac or pyloric ends of the stomach are involved; it is correspondingly less so when the wound is related to the body of the stomach.

Wounds of the curvatures of the stomach, with the greater destruction which invariably accompanies them, are associated with severe symptoms of collapse. The clinical features are also influenced by the condition of the stomach at the time of injury; if the stomach contains a quantity of food the wound is followed by more intense clinical features than if the organ had been empty.

Treatment.

These remarks are of course confined to operative treatment. If by examination we are confident that the stomach is injured, we have found it advisable to employ a left rectus incision, either splitting or retracting the muscle; this incision gives good approach to any part of the organ, occasionally it is necessary to enlarge it laterally. When the situation of the wound is doubtful we have used an incision parallel to the left costal margin. After exposure an examination is made of the anterior surface and lesser curvature of the stomach, and of the region of the cardiac orifice. The anterior layer of the great omentum is torn through, and the greater curvature and the posterior surface are thoroughly passed in review. We have met with conditions which called for three different lines of treatment, either singly or combined, the different lines of treatment being: (1) Simple suture (Cases i and ii); (2) gastro-enterostomy (Case v); (3) pylorotomy or resection of a portion of the stomach, usually combined with a gastro-enterostomy (Case vi).

In regard to simple suturing some situations are infinitely more difficult of access than others—for example, in a wound at the cardiac end of the stomach and near the lesser curvature we have experienced extreme difficulty in closing the opening. It has been our principle to excise the wound edges, thus preparing a more suitable surface for suturing and healing, afterwards closing the wound with a primary approximating and a secondary invaginating linen thread suture. Gastro-enterostomy is indicated when there is an extensive wound of the dependent part of the greater curvature of the stomach; the anastomosis may be done on the principle introduced by Kocher, but more usually the position and type of anastomosis will have to be modified by the existing conditions. Wounds of the pyloric end of the stomach are often so extensive that it is necessary to remove the damaged portion of stomach with closure of the open ends, and a secondary gastro-enterostomy.

If the peritoneal surface has been grossly soiled with stomach contents, we have washed out the cavity, draining it suprapubically with a Koith's drainage tube. In perforation of the posterior wall of the stomach with infection of the cavity of the lesser sac of the peritoneum we practise drainage of this space by a tube passed posteriorly above the pancreas.

Synopsis of Cases.

CASE I.

Pte. B. H., West Riding Regiment. Wounded with a rifle bullet at 10.30 a.m.; he was admitted to hospital at 2 p.m., and was operated on within four hours of receiving the wound. The entrance and exit wounds were in the left epigastrium and left loin. There was pain complained of, and sickness containing blood-stained matter; there was the usual accompanying abdominal rigidity. The general condition was good, and there was no marked collapse. The abdomen was opened in the left rectus line; perforations were found through anterior and posterior walls of the body of the stomach; in addition, the jejunum was perforated just beyond the duodeno-jejunal flexure. The perforations were closed with sutures, and the usual drainage was established. The patient made an uninterrupted recovery, and was discharged to the base.

CASE II.

Pte. A. F. H., Royal Engineers, was wounded by a rifle bullet at 6.30 p.m. on August 28th, 1915, and admitted to

hospital at 11 a.m. August 29th. The entrance and exit wounds were in the left epigastrium and left loin; great abdominal pain was complained of, and the patient was practically pulseless. The abdominal cavity contained a quantity of blood, and there was an effusion of blood into the left pleural cavity. So complete was the collapse that operation was delayed for three hours, and during that period various restorative measures were carried out. When operation was performed access was gained to the abdominal cavity by an incision parallel to the left costal margin. The abdominal cavity was full of blood; there was a wound of the stomach where the lesser curvature joins the oesophagus, and from it stomach contents were escaping; the profuse haemorrhage had apparently originated from a branch of the coronary artery. With great difficulty the perforation was sutured; the peritoneal cavity was washed out, and drainage secured. The patient died about two hours after the completion of the operation. *Post-mortem* examination showed that in addition to the wound of the stomach the lower lobe of the left lung was perforated, while the pleural cavity contained a large quantity of blood.

CASE III.

Pte. B. W., King's Royal Rifles. Wounded at 7 p.m., September 11th, he was admitted to hospital at 10 p.m. of the same date. There were entrance and exit wounds in the left back and loin. There were the usual signs of injury to the abdominal viscera; there was a considerable degree of collapse, the pulse-rate on admission being 130. The abdomen was opened by an incision running parallel to the left costal margin. It was found that the projectile had grazed the left end of the greater curvature of the stomach; in addition there was a perforation of the splenic flexure of the colon. The perforations were closed with sutures and drainage established. On the sixth day a faecal fistula developed from the colon wound, but otherwise a good recovery was made.

CASE IV.

Pte. H. W., Rifle Brigade, wounded at 10 p.m., August 29th, 1915. He was admitted to hospital at 2.30 a.m. of the following day. On admission it was found that the collapse was so intense that any operative procedure was entirely out of the question; he died a few hours after admission. *Post-mortem* examination showed that there was a large tear in the greater curvature of the stomach; in addition the bullet had passed through the left lung, and the pleural cavity contained a quantity of blood. This case was not operated on, but we have included it to show the greater degree of severity and collapse which follows wounds of the greater curvature of the stomach. The patient was admitted about four hours after sustaining his wound, but even at that early period he was entirely beyond operative aid.

CASE V.

Pte. G. H., Yorks and Lancs. There was a shell wound of the left hypochondriac region sustained at 8 a.m. of September 23rd, 1915; he was admitted to hospital at 4.30 p.m. of the same day. There were all the signs of injury to the abdominal viscera, and, in addition, it was obvious that the patient was bleeding profusely internally. The abdomen was opened through the left rectus; it contained a large amount of free blood mixed with gas. Along the greater curvature of the stomach there was a wound about two and a half inches long; the position of the wound was such that it permitted of a gastro-enterostomy being done between the open wound and the jejunum. The edges of the stomach wound were excised. In addition to the stomach wound there were seven perforations in a two and a half feet length of small intestine, necessitating resection and lateral anastomosis. The patient survived the operation for about eight hours and then died of collapse. The case demonstrates the suitability of a gastro-enterostomy under certain conditions.

CASE VI.

Cpl. A. C., King's Royal Rifles. Wounded at 6 p.m., September 24th, 1915. He was admitted to hospital at 1.30 a.m. of the following day. On admission there were all the signs of

injury to the abdominal viscera, but the collapse was too great to permit of immediate operation; operation was therefore delayed for two hours. Upon opening the abdomen it was found to contain a large quantity of blood, there was a perforation through the antrum pylori with a small entrance, and a large blown-out exit wound; in addition there were five perforations in the upper end of the jejunum. The damaged portion of stomach, the pylorus, and a portion of the body of the stomach, were removed, the open ends were closed, the damaged loop of intestine was resected, an anastomosis done, and a gastro-enterostomy performed between the body of the stomach and a loop of jejunum. This patient lived for twenty-four hours; during that period his pulse remained good and there was no sickness. He died eventually with extreme suddenness. This case illustrates the occasional necessity of removing a portion of the stomach.

WOUNDS OF SMALL INTESTINE.

Under this heading we have a total of twenty-one cases to consider.

Morbid Anatomy.

Among the series we have had cases of bomb, bullet, and shell wounds, and each of these varieties have distinctive features. Bomb fragments produce small and multiple wounds with slight evagination of the edges, but with a marked tendency to surrounding ecchymoses and haemorrhage (Cases XI and XXIII).

Bullet wounds, when caused by a projectile travelling at a great velocity and fired at a comparatively short range, are small perforations, with slightly larger exit than entrance wounds (Case XXII). Bullets travelling at a lower velocity result in considerable destruction of the gut wall.

When the projectile passes across the long axis of the gut it may pierce it through and through, but sometimes it tears it open as though it had been cut by a knife (Case XXIV). Bullets passing obliquely through or in the long axis of the gut produce extensive injuries; if in the long axis of the gut the bowel is torn completely open (Case XIII); if the intestine has been struck

obliquely there are two large perforations, one on each side, with an intervening bridge of tissue (Case XIV).

The damage produced by shell fragments is usually very extensive (Case XV), but if the force of the fragment is nearly spent, our experience has been that the wound is no larger than the fragment which caused it—in one

instance we have found the fragment of shell embedded in the gut wall (Case XVIII).

As regards position, wounds of the free edge of the gut are more extensive than those which occur at the mesenteric border. Correspondingly, wounds of fixed parts of the small intestine—for example, duodeno-jejunal flexure and the ileo-caecal junction—are less extensive than wounds of the freer portions of the gut.

Haemorrhage from small intestine is, as a rule, severe, especially when the wound has occurred in the jejunum. It is remarkable how rarely there is a massive escape of contents from the lumen of the gut—we have never seen it occur to any marked degree—apparently there is a complete inhibition of peristalsis for some time subsequent to the injury. Further, the less the damage to the gut and

Fig. 1 (to illustrate Case IV)—Bullet wound of the greater curvature of the stomach.

Fig. 2.—Anterior view of the pylorus, showing the small entrance wound.

Fig. 3. Posterior view of the pylorus, showing the large exit wound.

Figs. 2 and 3 (to illustrate Case VI).

the fewer the number of perforations, the more likelihood is there of extensive peritoneal soiling. We believe the converse holds good.

When the gut is injured it is rarely that the mesentery escapes, and one is exceedingly apt to overlook a wound in this region. When a large mesenteric vessel is cut the haemorrhage is rapidly fatal; but even in division of a

FIG. 4 (to illustrate Case xxii).—Four feet of gut containing perforations from a machine gun bullet. The bullet has passed with a high velocity through various coils of gut, passing across the long axis of the gut. The resulting damage is not extensive.

comparatively small vessel or series of vessels the haemorrhage is progressive, a characteristic which is curiously peculiar to intra-abdominal bleeding. When the blood vessels in the mesentery are damaged, one is faced with the question whether the viability of the associated gut is or is not interfered with. In this relation we have observed that while interference with the mesenteric blood may not actually endanger the viability of the gut that portion of gut is particularly liable to a subsequent distension which may pass on to an actual paralysis.

There is nothing characteristic about the superficial wound. Unless one is prepared for it, one is at first apt to overlook the fact that bullet wounds of the buttock are liable to be followed by evidences of injury to the abdominal viscera.

Clinical Features.

The clinical features are those of commencing peritonitis coupled with the evidences of a rapid and progressive haemorrhage. The facial expression is one of intense distress, pallor may become evident and deepen. The pulse becomes progressively and rapidly quicker and weaker. General abdominal pain is complained of, the pain being accentuated at intervals. There is frequently retention of urine. Sickiness comes on, and during the attacks of vomiting the abdominal pain is intensified. The temperature at first falls, and after some hours begins to rise. As a rule there is fixation of the abdominal wall, and the respirations are largely thoracic in type. Palpation elicits general tenderness, and palpation confirms the muscular rigidity which exists. Under the influence of morphine, and sometimes when the intra-abdominal bleeding is profuse, we have seen the muscular rigidity of the abdominal wall almost disappear. By percussion it is frequently possible to demonstrate the presence of dullness in the flanks and the diminution of liver dullness.

In later and untreated cases the clinical features are those of acute general peritonitis.

Treatment.

Later there are described measures which we have carried out preliminary to all abdominal operations for this class of case—measures which are intended to antagonize the shock and loss of blood which occurs. As a preliminary to operating for perforating wounds of the small intestine these precautionary methods are of the highest practical importance, as the amount of shock and the loss of blood in these cases are often exceptionally severe.

To open the abdominal cavity we have almost invariably used a middle-line incision; it is important that there should be no hesitation in making the incision one of considerable length. In localizing the sites of injury we have followed a well-defined routine. After opening the abdomen the caecum is identified, and from it the small intestine is traced upwards, beginning with the lower end of the ileum. As each perforation of the gut is exposed it is wrapped up in a small moist swab; to one side of the swab a length of tape is stitched; this is slipped through the mesentery and doubled twice round the gut covered by the swab; in this way each perforation is marked and at the same time there is less chance of a massive infection from the injured part. The whole length of the small intestine must be examined before any decision as to treatment is arrived at; there is nothing more disconcerting than to deal with a perforation by resection and to find that a few inches further on there is another perforation which could have been included in the same procedure. When the degree of damage to the gut has been brought under review there are three varieties of operative treatment which may be followed; these are: (1) Simple suture of the perforations; (2) resection of the damaged intestine, followed by a lateral or end-to-end anastomosis; (3) resection of the damaged intestine, with an accompaniment of a temporary enterostomy.

1. Simple Suture of the Perforations.

In the series of cases which came under our notice a small minority proved suitable to be dealt with by simple suture. In order to be suitable it is essential that the wound is small, without damaged edges and with an intact mesentery. Bomb fragments cause wounds which are most ideally suitable for suture.

The method has the obvious advantages of speed and simplicity of technique. There are certain distinct disadvantages: the suture may result in considerable narrowing of the gut lumen, and when there are a number of similar sutures within a short distance of each other the multiple narrowing becomes a very real objection. The second objection is that a suture, unless very complete, is apt to be followed by a local sloughing of the part. The edges of the perforation are devitalized and the microscope has shown that actual necrotic changes can be distinguished in the tissues for some distance around the wound.

FIG. 5 (to illustrate Case xxii).—This illustration demonstrates the pouting appearance of the mucous membrane at the point of exit.

In the suture operations which we have done we have not excised the wound edges and we have used linen thread as the medium for stitching (Cases VII, VIII, IX, X, and XI).

2. Resection of the Damaged Intestine followed by Lateral or End-to-end Anastomosis.

There are certain indications which necessitate this method of treatment: multiplicity of the perforation, extent of the degree of the perforation, and involvement of the related mesentery. We have distinctly favoured this method of treatment and we have preferred it at times when another method might have been chosen. Two disadvantages have been quoted—the complexity of the technique and the time which the operation entails. In regard to the second objection, we question if it takes any longer to complete a resection and anastomosis of gut than to do a multiple suture operation. The advantages are very great: the operation is a complete and a thorough one, the risk of damage following a mesenteric involvement is minimized; there are not the possibilities of local areas of sloughing as are so apt to occur in suture operations, and there is less possibility of subsequent stricture. Having weighed the choice of the operation, the question next

arises whether the anastomosis is to be a lateral or an end-to-end one. When we began this work we favoured and used an end-to-end anastomosis, on the ground that it could be accomplished in a shorter period of time than the lateral anastomosis. We discovered that this method was apt to be followed by a certain degree of paresis in the proximal segment with subsequent distension and eventual obstruction. On one occasion we had to perform a second short-circuiting operation to overcome the obstruction (Case xii).

FIG. 6 (to illustrate Case xii).—Eighteen inches of gut injured by rifle bullet. A portion of the lumen of the gut is torn widely open where the bullet has passed in the long axis of the intestine. The arrows illustrate the course of the bullet.

The gut appears to be predisposed to the distension from various causes: the general degree of nerve shock and more especially of sympathetic nerve shock; the paresis of Auerbach's plexus as a result of the blow; the presence of blood in the peritoneal cavity, and the degree of peritonitis which invariably is present. As a result of this disadvantage we began to employ a lateral anastomosis, and from it we have had undoubtedly greater satisfaction and better results. In point of time the lateral anastomosis takes a few moments longer in so far as it involves closing the open ends of the gut, but it apparently largely overcomes the possibility of distension of the proximal segment. We do not intend to enter into any details of the operation beyond mentioning that when the resected gut involves the extreme lower end of the ileum we have anastomosed the proximal bowel to the centre of the transverse colon. Short-circuiting, so to speak, by a unilateral short circuit the caecum, ascending colon and hepatic flexure, there are obvious mechanical advantages related to this method (Case xiv).

FIG. 7 (to illustrate Case xiv).—Two feet of the lower ileum injured by rifle bullet. Two portions of the gut have been entirely destroyed by the projectile.

3. Resection of the Damaged Intestine with the Accompaniment of a Temporary Enterostomy.

Fortunately we have only had occasion to have recourse to this most unsatisfactory procedure in one instance (Case xxv). It is justified when rapidly developing collapse necessitates that the operation be finished as quickly as possible; the damaged bowel is cut away and the open ends are sutured to the skin wound.

When there is gross soiling of the peritoneal cavity we have washed out the abdominal cavity with hot saline solution, draining subsequently suprapubically with a glass Keith's tube.

Synopsis of Illustrative Cases.

CASE VII.

Pte. B. T., Middlesex. There was an entrance wound in the left umbilical region; there was no exit wound apparent. There were signs of injury to the abdominal viscera, but the general condition was good. From the wound a coil of small intestine was prolapsed. At the operation the wound was enlarged; two perforations were found in the lower end of the ileum; the perforations were closed with purse-string and inverting sutures. Beyond a subsequent slight infection of the

retroperitoneal tissues, which required drainage, the patient made a good recovery.

CASE VIII.

Pte. B. H., West Riding Regiment. Entrance and exit wounds were sustained by a bullet received four hours before admission; the general condition was good. Operation revealed two perforations of the jejunum just beyond the duodeno-jejunal flexure. These were closed with purse-string and invagination sutures. This case in addition showed two perforations of the stomach. Drainage was secured. The patient made a good recovery.

FIG. 8 (to illustrate Case xxiv).—The gut has been divided almost entirely across in four different places. All these injuries have been caused by a single rifle bullet. The round worm shown *in situ* was divided by the bullet.

CASE IX.

Pte. P. H., Northumberland. This patient was wounded on the 26th of the month, but owing to military exigencies it was the evening of the 29th before he was admitted for operation; there was then an entrance wound below the umbilicus, together with all the evidences of extensive general peritonitis. It was doubtful whether operation was advisable, but it was decided to attempt it. A single perforation was found in the lower end of the ileum; this was sutured and drainage was secured. Subsequent to the operation the patient improved considerably; he apparently was on the road to recovery, the bowels moving well, when, a week after the operation, he died suddenly from what apparently was heart failure.

FIG. 9 (to illustrate Case xviii).—A length of jejunum removed for injury by a fragment of shell. The intestine showed six perforations, and a fragment of shell was found embedded in the wall of the gut. s. Shell fragment.

CASE X.

Pte. T. S., East Lancs. There were entrance and exit wounds, the bullet having entered the right buttock and come out anteriorly below the umbilicus. There were the usual evidences of injury to the abdominal viscera, and the general condition was fair. Operation showed a single perforation in the upper end of the ileum; there was extensive soiling of the peritoneal cavity and a commencing general peritonitis. The perforation was closed by suture. Four days after operation the patient succumbed to the general peritonitis which was present.

CASE XI.

Pte. A. H., Black Watch. This man was wounded by a bomb explosion, and there were a number of entrance wounds in the left flank. There was intense shock, the pulse being 150. A number of fragments had entered the abdominal cavity and there were all the signs of injury to viscera. In addition two fragments had entered the left lung and a third entered the spinal cord, producing complete paraplegia below the eighth dorsal segment. After waiting some hours for a possible improvement operation was carried out. The abdomen contained a large amount of blood. There were four perforations

in the jejunum about 8 in. below the duodeno-jejunal flexure; each was closed with suture. In addition the transverse colon was perforated at its centre; in the descending colon there were six through-and-through perforations; these wounds were sutured. The abdomen was washed out and drained suprapubically and in the left flank. As far as the abdominal condition is concerned, we believe we are justified in looking on this case as a success; his eventual history, however, shows that he ultimately died of a gradual ascending spinal meningitis secondary to the infected wound of the spinal column.

The above cases are illustrative of the suture operation.

CASE XII.

Pte. G. H., Yorks and Lancs. In this case the injuries were the result of a shell wound. There was intense collapse. The abdominal cavity was filled with blood; there were seven perforations in a two and a half feet length of small intestine (upper end of ileum); practically all of the perforations were very large wounds. Three feet of small intestine were removed and a lateral anastomosis completed. In addition, the stomach was extensively torn, necessitating a gastro-enterostomy. The patient survived for eight hours and died of collapse.

CASE XIII.

Pte. W. G., Seaforth Highlanders. On admission the patient was collapsed; there was progressive haemorrhage from both superficial wounds and general abdominal rigidity. The operation was performed under spinal anaesthesia. The deep epigastric artery of the left side was severed, hence the superficial bleeding; the abdominal cavity was full of blood. In the upper end of the ileum there were three perforations—two small and one exceedingly large—opening up the gut for about one and a half inches. Nine inches of gut were removed and an end-to-end anastomosis completed. Forty-eight hours later signs of obstruction developed and the abdomen was again opened under spinal anaesthesia; the proximal segment of gut at the anastomosis was distended, and there was a large effusion of blood into the mesentery of this portion of the gut. A lateral anastomosis was done, short-circuiting the end-to-end suture. The patient made an uninterrupted recovery; two months later we have heard from him as being in excellent health.

CASE XIV.

Pte. L. T., Black Watch. This man was wounded in the right buttock, and six hours after having received the wound he was admitted to hospital; there were all the signs of injury to abdominal viscera. The operation was done under spinal anaesthesia. When the abdomen was opened a perfect fountain of blood escaped; in the lower two feet of ileum there were six perforations—in two instances the gut was shattered to pieces. The damaged intestine was removed and a lateral anastomosis completed between the ileum and the centre of the transverse colon. The patient made an uninterrupted recovery, and three months later he informed us that he was enjoying excellent health.

CASE XV.

Cpl. A. C., King's Royal Rifles. Seven and a half hours elapsed since receipt of a bullet, which had passed through the abdomen from side to side. There was intense collapse, and operation was delayed for two hours. At operation there were found to be five large perforations in the upper part of the jejunum. In addition the transverse colon was torn across and the stomach was almost divided in two places. The damaged loop of small intestine was removed and a lateral anastomosis completed; the stomach wounds were repaired and a gastro-enterostomy done; the damaged colon was brought out, and a colostomy completed. The patient stood the operation remarkably well, and he survived for over twenty-four hours; during that time there was no sickness and his pulse remained good. He then suddenly collapsed and expired.

CASE XVI.

Pte. E. H., King's Royal Rifles. The wound had been sustained in the right loin, and the bullet had taken an oblique path, being embedded below the left costal margin. Fifteen hours had elapsed since receipt of the injury, and the collapse was intense. After waiting some time, and taking measures to overcome the collapse, it became obvious that there would be no improvement, and that the patient was bleeding rapidly inter-

nally. The abdomen was opened; 18 in. from the duodeno-jejunal flexure the gut was torn across in three places; there was profuse bleeding from a large branch of the mesenteric artery. The damaged gut was resected, and the bleeding arrested. The patient died thirty-six hours after operation. *Post-mortem* examination showed no other lesion, and death was due to haemorrhage and collapse.

CASE XVII.

Sergt. S. P., Worcesters. The entrance and exit wounds were in opposite flanks. There was complete collapse, seventeen hours having elapsed since the receipt of injury. There were all the evidences of general peritonitis, and the abdominal cavity contained a quantity of fluid. Operation was conducted under spinal anaesthesia. The peritoneal cavity was found to be full of blood. In 2½ feet of small intestine (lower end of jejunum) there were seven perforations, several of them tearing the gut entirely across. During the operation there was progressive bleeding from the retroperitoneal tissues; its source could not be found. After the operation the patient steadily sank, and died ten hours later.

CASE XVIII.

Pte. A. H., Lincolns. Shell wound. There were entrance and exit wounds in the right epigastrium and left flank. There were all the signs of injury to the abdominal viscera, but the degree of collapse was not marked. Operation revealed the abdomen to be full of blood and gas. Twelve inches of jejunum were extensively damaged by six perforations. In the wall of the gut the fragment of shell was embedded. The transverse colon was torn across at its centre. The damaged small intestine was removed, and a lateral anastomosis completed. The perforated transverse colon was converted into an efficient colostomy. The patient made an uninterrupted recovery.

CASE XIX.

Pte. H. B., Rifle Brigade. On admission this patient showed entrance and exit wounds from the right buttock to the left hypochondrium. There was profuse external haemorrhage. The man was practically pulseless, but he improved somewhat after the intravenous transfusion of saline. There were all the signs of a generalized peritonitis. Operation was conducted under spinal anaesthesia, but the patient succumbed before any operative procedure could be carried out. Subsequent investigation showed that there were ten wounds throughout the small intestine, nearly all of which had torn the gut entirely across. For a distance of 6 in. in one part the lumen of the gut was entirely destroyed. In addition, the iliac colon was divided and the internal pudic artery was severed as it lay in Alcock's canal.

CASE XX.

Pte. H. C., Wiltshire Regiment.

The entrance and exit wounds were from side to side of the abdomen, and from the exit wound there was a considerable protrusion of omentum. On admission the general condition was good, but there were all the evidences of injury to the abdominal viscera. When the abdomen was opened the cavity was found to be filled with blood; there were seven perforations in the upper four feet of jejunum, and in two instances the gut was shattered to pieces. The damaged gut was removed, and as the proximal portion was too fixed to permit of a lateral anastomosis, an end-to-end suture was carried out. The patient died forty-eight hours after operation. *Post-mortem* examination revealed an intense peritonitis, especially in the upper part of the abdomen, and this apparently was the cause of death.

CASE XXI.

Cpl. B. A. E., Durham Light Infantry. There was an entrance wound in the left buttock; there were the signs of injury to the abdominal viscera, together with symptoms of intense collapse, pulse being 130. Ten hours had elapsed since the injury was received. The abdomen was opened in the middle line under spinal anaesthesia. There was an immense effusion of blood. Three feet of the ileum was found to be extensively damaged and torn with eight perforations. The damaged gut was removed and a lateral anastomosis completed. The patient succumbed a few hours after operation.

CASE XXII.

Pte. R. J. W., Irish Guards. The patient was shot at close range by a machine-gun bullet. He was operated on within two

FIG. 10 (to illustrate Case XII).—Wounds of small intestine caused by a fragment of common shell. Note the very extensive degree of the injury in each case.

hours of receiving the injury, and his general condition was good; there were all the signs of injury to the abdominal viscera. Operation showed that the abdominal cavity contained a large quantity of blood. There were eight perforations in the lower end of the jejunum, and it was necessary to remove four feet of intestine. This was done and a lateral anastomosis completed. The ureter was also injured. The patient made a complete and uninterrupted recovery.

CASE XXIII.

Pte. McJ., Black Watch, was wounded in a bomb explosion, and there were at least five penetrating wounds of the abdomen. When admitted he was very collapsed, the pulse being 150. Operation was delayed for some time and then performed under ether anaesthesia. There was a great amount of effused blood. Tracing the small intestine, there were fourteen perforations in the lower end of the jejunum, and it was necessary to remove six feet of gut; a lateral anastomosis was completed. There were four perforations in the descending colon, and these were closed with suture; a single large perforation in the transverse colon was converted into a colostomy. The patient passed a comfortable night and was remarkably well throughout the following day. He died somewhat suddenly on the second morning after operation.

CASE XXIV.

Pte. C. R., Seaforth Highlanders. There was a single entrance wound in the left buttock. It was interesting to note that there was no rigidity on palpation, but pain was complained of. Collapse was so intense that immediate operation was impossible. After some hours there was a slight improvement and operation was then performed under ether. There was an enormous quantity of free blood in the peritoneal cavity. There were four large perforations of the lower end of the ileum, three of them tearing the gut completely across; in addition there were three extensive bruises of the gut and two tears in the mesentery, which were bleeding profusely. Eighteen inches of small intestine were removed. The iliac colon was so damaged that it was necessary to perform an inguinal colostomy. The patient died of shock eight hours after operation.

The above cases are illustrative of the operation of resection and anastomosis of the intestine. In discussing the treatment of perforating wounds of the intestine we mentioned the possibility of having in some cases to do a resection of intestine, with the formation of a temporary enterostomy. It is an unsatisfactory operation, and fortunately we have had to resort to it in only one instance. That instance we now quote:

CASE XXV.

Pte. W. J., Black Watch. There was an entrance wound below the umbilicus, and there were evidences of injury to the abdominal viscera; in addition there was extreme collapse. On opening the abdomen there were found to be four perforations in the small intestine; in addition the rectum and the bladder were perforated. A suprapubic cystotomy and a colostomy were performed; there was no time to carry out an anastomosis of the gut, and the open ends of the intestine were stitched to the skin edges, after cutting away the damaged gut. The patient succumbed from shock a few hours after operation.

In conclusion we quote two cases the seriousness of whose general condition precluded any possibility of operative treatment:

CASE XXVI.

Pte. T. H., Cheshires. There was an entrance wound in the left buttock. The collapse was so intense that death ensued about one hour after admission. Examination showed eight perforations in the lower end of the ileum, two perforations in the lower end of the jejunum, and a complete severance of the iliac colon. There was a quantity of loose bone in the abdominal cavity.

CASE XXVII.

Sapper H. J., Royal Engineers. This man was wounded with shrapnel, and there was a large entrance wound in the left

flank. When admitted the patient was pulseless and unconscious, and he died one and a half hours after admission. Examination showed eight perforations in the lower end of the ileum with extreme destruction of the gut.

WOUNDS OF COLON.

We have a series of twelve cases to record, but several of these have been already mentioned in dealing with stomach and small intestine injuries. The general remarks one would make are very similar to those we have already mentioned in relation to small intestine, but there are several points which are more or less peculiar, and these will be dealt with.

Morbid Anatomy.

The effects of shell, bullet, or bomb vary exactly as they do in small intestine. Very similarly also the damage appears to vary according to whether the colon is fixed or free—for example, the transverse colon and the free loop of the iliac colon are frequently torn entirely across, while in the more fixed points simple perforation is the rule.

Effusion from a wound of the colon has a liability to be shut off and localized, more especially when the wound occurs in the ascending or the descending colon; it is quite common to meet with a collection of faecal and semi-purulent matter entirely shut off and opening into the underlying colon

(Case XXVIII). It is, of course, an established fact that if the infection does not become localized, the peritonitis from a large intestine wound is intensely virulent.

Clinical Features.

The clinical features are very similar to those of small intestine injury. They are, primarily at least, not so widespread, and early sickness as a rule is absent.

Treatment.

We have drawn attention to the liability which colon wounds have of becoming localized, and this fact has a bearing on the operative treatment which one employs. The bearing is that if the patient comes under treatment at a period longer than twenty-four hours after the receipt of the injury it is a wise principle, primarily at least, to enlarge the original wound on the possibility that the infection is becoming localized. At an earlier period than twenty-four hours it is probably better to open the abdomen through a separate incision.

We have been impressed with the risk which one runs of overlooking injuries to the colon, and in one instance we have made this mistake (Case XXV). The risk is greatest when the wound lies in one or other of the flexures of the gut.

The actual operative treatment may be summarized in two methods: (1) Simple suture; (2) simple suture with

FIG. 11 (to illustrate Cases II and XXIII).—Bomb wounds of the small intestine. Note the comparatively small size of the wounds, the surrounding ecchymoses, and the suitability of such cases for suture.

colotomy. The operation of resection may be left out of account; it is rarely advisable to practise it in this type of surgery. We have favoured the use of a colotomy in combination with the operation of suture; there are the obvious advantages that it increases the safety of the suture, while it obviates the passage of faecal matter through the damaged gut.

In wounds of the ascending and the descending colon we have been impressed with the advisability of draining the retrocolic space by a tube passing into the loin.

CASE XXVIII.

Sergt. B. A. The wound had been sustained with a fragment of shell about twenty-four hours previously. His general condition was good, and local signs pointed to the fact that the injury and infection were limited to the neighbourhood of the wound. The original wound was opened up, exposing a small collection of faecal and semi-purulent matter; the containing cavity communicated with a wound in the ascending colon. The cavity was drained, and a faecal fistula developed. Recovery.

CASE XXIX.

Pte. B. W., King's Royal Rifles. The entrance and exit wounds were in the left loin; there were the signs of injury to the abdominal viscera, and a considerable degree of collapse. The abdomen was opened parallel to the left costal margin. There was a wound in the outer side of the splenic flexure of the colon; the wound was closed with suture and drainage established in the flank. A faecal fistula developed on the fourth day. Recovery. In this case the stomach also was injured.

CASE XXX.

Pte. O. H., Lincolns. This man was wounded with a fragment of shell. Opening the abdomen, in addition to wounds of the small intestine, it was found that the transverse colon was divided at its centre. The transverse colon was brought out, and so repaired that a single Paul's colotomy tube was fastened into the gut lumen at the site of injury; a length of small intestine was resected. Recovery.

CASE XXXI.

Rifleman P. F., Rifle Brigade. There were entrance and exit wounds in each loin respectively, with complete abdominal rigidity. The general condition was good. The abdomen was opened in the middle line. There was a large quantity of free blood in the peritoneal cavity. Two large perforations were found in the ascending colon; a local colotomy and repair was done. The bullet in its course had passed through the spinal column, but without damaging the spinal cord. He remained well until 6 a.m. of the following day; his pulse then suddenly failed, and he died an hour later. Death was apparently due to peritonitis and shock.

CASE XXXII.

Pte. S. J., North Staffords. The injuries were the result of shell wounds. There were three entrance wounds on the outer side of the hip. The patient was practically pulseless. Operation was delayed for two hours and restorative means were applied. Operation was finally carried out under spinal anaesthesia. There was a large perforation of the iliac colon immediately above the loop; at a higher level the posterior wall of the descending colon was torn. Repair and colotomy were done. Death from shock ensued twelve hours later.

CASE XXXIII.

Cpl. H. J., Royal Irish Rifles. A bullet wound had been sustained twenty-four hours previously. There was a much greater degree of collapse than seemed compatible with the injury. The entrance wound was enlarged; the iliac colon was perforated in two places; there was no evidence of injury to other viscera. Repair and colotomy were performed. Throughout the first and second days following operation the patient steadily improved; on the third morning he was exceedingly well, when suddenly about midday he developed an extensive secondary haemorrhage. At this point the case passed out of our hands, and we are unaware of his further history. (We have since heard that the patient died.)

CASE XXXIV.

Pte. T. H., North Lances. There were entrance and exit wounds in opposite loins; the exit wound admitted two fingers. There were all the signs of injury to the abdominal viscera. On opening the abdominal cavity it was found to contain a large quantity of blood; there was a large wound of the postero-external surface of the hepatic flexure, and there was also an extensive tuberculous peritonitis. With difficulty the wound in the colon was sutured. The patient died nine hours later. Post-mortem examination showed the presence of a generalized tuberculosis.

CASE XXXV.

Pte. B. A., D.C.L.I. This patient was admitted suffering from a bayonet wound of the abdomen, the weapon having entered below the left costal margin. There were no evidences of abdominal infection, but the abdominal cavity was opened. No perforation was found, and there was neither free blood nor evidence of infection. The following day there was all the evidence of a general peritonitis; investigation showed that we had overlooked a small perforation below the splenic flexure. The patient later succumbed to the peritonitis.

This last case illustrates the liability of overlooking small wounds of the colon when they are situated in out of the way places, such as the hepatic and splenic flexures.

CASE XXXVI.

Pte. F. A., Worcesters. This patient was admitted suffering from a bullet wound of the left loin. Operation showed that the bullet had grazed the outer wall of the descending colon; it had not penetrated the mucous coat of the gut. The damage was repaired and local drainage was secured. On the second day after operation there was a suspicion of a faecal fistula, but this disappeared. The patient made a complete recovery.

CASE XXXVII.

Pte. M. H. W., R. W. Fusiliers. A fragment of common shell had passed through the left iliac fossa; the pelvis was fractured, and omentum was protruding from the wound. Operation showed that about one inch of the sigmoid flexure was entirely destroyed. A colotomy was performed and drainage secured. The patient made a good recovery.

WOUNDS OF SPLEEN.

In two cases damage to the spleen rendered it necessary to perform the operation of splenectomy.

Morbid Anatomy.

In one case a bullet was responsible for the damage; it had passed through one pole of the spleen, tearing it into two portions and splitting it in all directions. One portion of the spleen could not be recovered from the abdomen at operation; it appeared later from the wound as a small slough. In this instance the kidney was badly damaged (Case xxxviii). The second case was of even greater interest than the first, because apparently the injury to the spleen was not a primary but a secondary result.

The bullet had passed comparatively superficially through the left flank, fracturing the lower ribs in its passage; the sharp fragments of ribs had been drawn inwards, and these fragments were responsible for the damage to the spleen. The movement of the spleen with each respiration had increased the damage until at the time of operation the organ was reduced to pulp. This is the second instance we have seen of this form of injury to the spleen; the first was not under our immediate care.

Clinical Features.

The first case was observed about six hours after the injury was sustained. The general condition was wonderfully good, pulse being only 88 per minute; there was some muscular rigidity along the left side of the abdomen; the abdominal cavity contained a quantity of free fluid; the temperature was normal. These, together with the entrance and exit wounds, were the only clinical evidences. The second case was different in so far as forty-eight hours had elapsed since the receipt of the injury; during that time haemorrhage had been continuous. When admitted the patient was pulseless, there were all the evidences of intense haemorrhage, the abdomen was distended, rigid, and contained a large amount of fluid.

Treatment.

In both cases we found it necessary to remove the damaged organ; the idea of suturing could not be entertained. We made use of an incision parallel to the costal margin, and no difficulty was encountered in removing the part. Drainage was secured in the flank and a Keith's tube was passed through a suprapubic opening into the pouch of Douglas. In the three cases which we have observed the injury to the spleen was complicated in two cases by damage to one of two other organs, the left kidney and the splenic flexures of the colon.

It is advisable that care be taken during operation that these complicating injuries be not overlooked.

Synopsis of Cases.

CASE XXXVIII.

Cpl. S. C., Royal Engineers. There was an entrance wound over the spinal column, and an exit wound in the left loin; there was left abdominal rigidity and evidence of internal haemorrhage. The abdominal cavity was opened; it was found to contain a large amount of blood. The spleen was shattered;

FIG. 12 (to illustrate Case XXXVIII).—Injury to spleen caused by rifle bullet. The lower portion was entirely detached and could not be recovered at operation; it was, however, recovered later.

its pedicle was ligatured, and the remains of the organ removed. The left kidney was so extensively damaged that its removal was also necessary. Uninterrupted recovery.

CASE XXXIX.

Pte. B. A., Grenadier Guards. This man was wounded forty-eight hours before admission in the lowest ribs at the posterior axillary line; the wound was produced by a rifle bullet. On admission the patient was pulseless, obviously suffering intensely from haemorrhage; the abdomen was distended and rigid. Upon opening the abdomen its cavity was found to be full of blood, the spleen was disorganized into a mass of bleeding pulp, the lower ribs were fractured, and their sharp ends had been driven into the spleen. The spleen was removed,

FIG. 13 (to illustrate Case XXXIX).—Injury to spleen caused by rifle bullet. It is probable that much of the resulting destruction was due to the viscus being torn by the indriven and fractured ribs.

and the sharp bone fragments excised. Drainage was established in the flank and suprapubically. The patient died on the seventh day after operation; he apparently succumbed from heart failure.

WOUNDS OF LIVER, GALL BLADDER, AND DUCTS.

In discussing wounds of this region we shall bring a series of fourteen cases under review, but it must be understood that only a relatively small proportion of these required operation.

Morbid Anatomy.

Our knowledge of the morbid anatomy of these cases is based entirely on operative experience; we have had no post-mortem experience.

The close relationship of the right pleura and lung to the right lobe of the liver is responsible for the fact that a wound of the liver is very frequently accompanied by damage to the overlying lung or pleura. This fact is important, as the latter condition is apt to be overlooked. We have seen a case in which the lung wound had been unnoticed until the degree of fluid in the right pleura actually endangered the patient's life. It would appear to be unusual to have much destruction or disruption of the liver tissue; probably for this reason the occurrence of a post-traumatic jaundice is uncommon. There is generally an escape of blood into the peritoneal cavity, and occasionally it can be demonstrated in the retroperitoneal tissues.

We have only one instance to record of a wound of the ducts—a case in which the cystic duct was divided close to its entry into the gall bladder. Duct wounds are so frequently accompanied by injury to large vessels that the result is generally fatal before they can be given surgical assistance.

Clinical Features.

The clinical features may be remarkably scanty. If the wound has involved the lung and pleura the pulmonary signs frequently disguise the abdominal features. Generally there is pain complained of over the liver and beneath the right scapula. The pulse, temperature, and more especially the respiration, are increased. There is usually some rigidity of the upper part of the abdominal wall; we have observed that the rigidity is increased and becomes more generalized when there is a considerable effusion of blood into the peritoneal cavity. By percussion an effusion can sometimes be demonstrated in the right iliac fossa. One would expect greater interference with the excretory function of the liver than is actually the case. On only one occasion have we seen a large effusion of bile into the peritoneal cavity (Case XLV). Post-traumatic jaundice is exceptional, and when it occurs it generally indicates a septic change secondary to the wound. There is no alteration in the bile contents of the faeces, and the urine is free from bile.

Treatment.

We have only operated on such cases as showed progressive haemorrhage, or which, from the clinical features, we suspected to be complicated by wounds of other viscera.

In one instance we operated for a wound of the cystic duct (Case XL). In another instance a late operation was necessary on account of the accumulation of bile in the peritoneal cavity.

We have employed a Kocher's paracostal incision or the angled incision recommended by Mayo Robson; both incisions have given excellent access. The operation has generally been confined to investigation, plugging, and drainage.

Synopsis of Cases.

The following cases were operated on. It is unnecessary to give details regarding the cases which were unoperated on.

CASE XL.

Sergt.-Major P. W., Connaught Rangers. There was an entrance wound below the costal margin with an exit wound behind. There was general abdominal rigidity, an increasing area of dullness in the right flank, and evidences of general collapse. The abdomen was opened through an angled incision; it contained a quantity of blood and bile. The gall bladder was collapsed and the cystic duct was divided close to its entrance into the gall bladder. No other injury could be found beyond some scoring of the under surface of the liver. The divided duct was drained with a "dressed" rubber tube.

For two days there was a profuse discharge of bile; after that date it diminished and disappeared. Two months later the patient was in perfect health.

CASE XLII.

Pte. G. A., Royal Field Artillery. This man was wounded by a shrapnel bullet immediately above the right costal margin. His condition on admission was good, but some hours after admission signs of general peritonitis developed. The abdomen was opened; it contained a quantity of blood, and the upper surface of the liver was torn. The wound in the liver was drained with a dressed rubber tube. The patient made an excellent recovery.

CASE XLIII.

Rifleman R. J., Rifle Brigade. There were entrance and exit wounds below the right costal margin and in the right loin, with general abdominal rigidity. The abdomen was opened and found to contain a quantity of blood. The under surface of the liver was torn and fissured. Drainage was secured with a dressed rubber tube. An uneventful recovery was made.

CASE XLIII.

Pte. J. J., King's Royal Rifles. There were entrance and exit wounds in the right axilla and over the right kidney; the entrance wound was small, but the exit wound was large and admitted three fingers. The bullet had penetrated the liver, opened the extreme lower limit of the pleura, and passed through the extreme outer edge of the kidney. The wound was drained. For two days there were evidences of a urinary fistula. The discharge then ceased, and an uneventful recovery was made.

CASE XLIII A.

Pte. D. A., East Lancs. There was a large entrance wound over the tenth rib, caused by a fragment of common shell. The wound was enlarged, neighbouring ribs being resected. The fragment had opened the pleural cavity, torn the diaphragm, passed through the right lobe of the liver, and was removed from the muscles of the posterior abdominal wall. It measured 1½ in. by ¾ in. Efficient drainage was established, and an uneventful recovery was made.

CASE XLIV.

Cpl. C. H. W., Royal Berks. There was an entrance wound over the right scapula caused by a shrapnel bullet; the bullet could be felt beneath the skin, over the right costal margin. The projectile had obviously traversed the liver, but there being no abdominal symptoms, no operation was done. Two days later slight jaundice developed, and there was free fluid to be made out in the abdominal cavity. The following day the jaundice had deepened, and the amount of free fluid had increased; the abdomen was therefore opened. The abdominal cavity contained a large amount of free bile. Drainage was established, and the discharge eventually ceased.

Cases XLV to LII were unoperated on.

WOUNDS OF KIDNEY AND URETER.

We have experienced three cases of wounds involving the kidney and one case in which the ureter was damaged.

Morbid Anatomy.

In regard to the kidney wounds, in two cases the injury was comparatively slight, necessitating only a simple drainage. In the third case the kidney was so badly damaged that nephrectomy was necessary. But the apparent triviality of the kidney wound is sometimes no guide to the organic disintegration which occurs. Even in the slightest wounds the organ shows extensive microscopical changes of minute necrosis and haemorrhage.

Clinical Features.

In each of our cases we got our first indication of the kidney being damaged from the position of the wound. One would reasonably expect haematuria to occur; blood was present in the urine in the two comparatively slight cases with which we had to deal; in the severe injury the remainder of the pelvis of the kidney was blocked with blood clot, and there was no indication of haematuria.

Treatment.

Generally speaking, there are three possible operative procedures which one may be called upon to perform:

(1) Simple drainage; (2) suturing the kidney; (3) nephrectomy. We employed the first procedure in the two instances in which the damage was slight; a "dressed" tube was passed down to the kidney wound, and gauze was loosely packed around it. This method gave every satisfaction. We have had no suitable case in which to employ the second procedure.

One case demanded the operation of nephrectomy (Case LV). In this instance the spleen was removed in addition to the kidney; the operation was carried out transperitoneally.

In the majority of instances the operation will be done through an anterior incision, by reason of the fact that it is necessary to examine not only the kidney but also the general abdominal viscera.

Synopsis of Cases.

CASE LIII.

Pte. G. F., Rifle Brigade. Wounded by a bullet in the left loin; the projectile passed across the back without damaging the spine and emerged on the opposite side. The left posterior wound was enlarged. The descending colon had been stripped forwards from the kidney, and the projectile had grazed the outer border of the kidney. Drainage was secured, and the patient made a good recovery.

CASE LIV.

Pte. J. J., King's Royal Rifles. There was a small entrance wound in the right posterior axillary line; there was a large exit wound over the right kidney. The posterior wound was enlarged and the eleventh and twelfth ribs removed. The bullet had opened the pleura, damaged the liver, and passed through the outer edge of the kidney. Drainage was established; for two days there was a slight discharge of urine. Eventual recovery.

CASE LV.

Cpl. S. C., Royal Engineers. There was an entrance wound over the spine and an exit wound in the left loin. There was left abdominal rigidity and evidences of internal haemorrhage. The abdominal cavity was opened, and was found to contain a large amount of blood. The spleen was found to be shattered to pieces; it was removed; palpating the left kidney, it likewise was found to be in pieces. The peritoneum to the outer side of the colon was divided and the gut separated inwards; the remains of the kidney were removed; drainage was established in the flank. Recovery.

Wound of Ureter.

We have had a single instance of this injury, and we offer no comment beyond briefly describing the case.

CASE LVI.

Pte. R. J. W., Irish Guards. He was shot at close range in the abdomen, by a machine-gun bullet. On operation there were found to be eight perforations in the small intestine. In addition to blood, the abdominal cavity contained a quantity of urine; this was found to have escaped from a wound of the left ureter, where it passed into the pelvis. As the patient's general condition was grave, no attempt was made to repair the ureter wound, but a drainage tube was sutured in position, and drainage also established in the flank. In addition a resection of small intestine was performed. After the second day there was no discharge of urine, and the patient made an uneventful recovery.

WOUNDS OF BLADDER.

We have had the opportunity of dealing with four of these cases; three of them were examples of intraperitoneal rupture, the fourth was an example of an extraperitoneal wound.

Morbid Anatomy.

There were two facts which impressed themselves upon us. The first was that an intraperitoneal wound of the bladder is in nearly every instance complicated by wounds of other viscera, usually rectum and small intestine. The second fact is illustrated by Case LIX, in which a non-penetrating wound of the abdominal wall, sustained by a man with a full bladder, may produce a rupture of the bladder; details of the case are added.

Clinical Features.

The clinical features which are observed were complicated by the symptoms of other wounded viscera, except in one case (Case LIX).

The features were those of a somewhat slowly developing general peritonitis, with at first local pain over the bladder, and afterwards diffuse pain. In the intraperitoneal rupture the presence of free fluid in the abdomen could be demonstrated; in the extraperitoneal rupture there was a wound in the perineum, from which urine mixed with blood was escaping. In the uncomplicated case the degree of shock was less than in intestinal injury.

Treatment.

In the intraperitoneal rupture we adopted the operative procedure of a suprapubic cystotomy; in the extraperitoneal variety it was found to be sufficient to drain the bladder per urethram, while a local drain was established in the perineum.

Synopsis of Cases.

CASE LVII.

Pte. W. J., Black Watch. There was an entry wound immediately above the symphysis pubis; there was no exit wound. There were all the signs of extensive damage to the abdominal viscera, and shock was intense. Eight hours had elapsed since the injury. Operation showed a perforation of both walls of the bladder, five perforations in the lower end of the ileum, and a tear of the large intestine at the junction of iliac colon and pelvic colon. The bladder wounds were closed and a suprapubic cystotomy done; the colon wound was sutured and a colostomy performed above; a length of two feet of small intestine was resected. The patient died of collapse about ten hours after operation.

CASE LVIII.

Pte. H. B., Manchester Regiment. This man was wounded by a revolver bullet above and slightly to the left of the symphysis pubis; there was no wound of exit. There were the usual evidences of injury to the abdominal viscera. Operation showed a perforation of the bladder on its left lateral aspect, eight perforations of small intestine, and a perforation of the iliac colon. A suprapubic cystotomy was done, the small intestine was resected, and the wound of the colon treated by suturing and colostomy. The patient succumbed on the following day.

CASE LIX.

Cpl. O. L., 20th Infantry Brigade (German). This case is of special interest because we believe it to be an example of the rupture of a full bladder secondary to a superficial non-penetrating wound of the abdominal wall. There were entrance and exit wounds immediately below the umbilicus. Examination showed that these wounds communicated and were not perforating. There were, however, distinct evidences of infection inside the abdomen. There was no other evidence of wound or contusion. The abdomen was opened; it contained a large quantity of urine. The bladder wall was split on its antero-lateral wall, and the wound was partly extraperitoneal and partly intraperitoneal. A suprapubic cystotomy was performed and intra-abdominal drainage secured. Unfortunately a virulent peritonitis developed, to which the patient succumbed.

CASE LX.

Lance-Cpl. F. J., Royal Engineers. This man, while bending forwards, was hit by a rifle bullet in the perineum; the projectile emerged above the crest of the ilium on the left side. There was a considerable degree of collapse. The abdomen was rigid in its lower part; the patient had passed some blood-stained urine, and blood was escaping from the rectum. Operative measures were carried out under spinal anaesthesia. The abdomen was opened in the middle line; there was a perforation of the mesentery of the iliac colon; the gut was not damaged. The bladder contained a quantity of dark-coloured fluid—urine mixed with blood—but there was no intraperitoneal perforation. The abdominal wall was closed. The patient was now placed in the lithotomy position. A full incision was made in the left side of the perineum and the wound opened up along the lateral aspect of the rectum and bladder. Drainage tubes were placed in position by the side of each organ. A large catheter was passed into the bladder per urethram; the bladder cavity was washed out and the catheter fixed *in situ*. The bullet in its progress had fractured the lateral wall of the pelvis. For two days the lateral bladder tube discharged freely; the discharge then ceased and the tube was removed. The urethral catheter was kept in position for five days. After fourteen days this man was discharged to the base.

WOUNDS OF THE RECTUM.

Under this heading we only include those cases in which injury was sustained by that portion of the large intestine

which extends from the level of the third sacral vertebra to the anal canal.

Morbid Anatomy.

We have experienced two cases representative of this type of injury. In both instances the wound had been sustained in the left buttock; the bullet had at first pierced the gut extraperitoneally, then, emerging intraperitoneally, it had produced further extensive damage in the small intestine. In both instances the lateral wall of the pelvis was fractured, and there was most profuse bleeding from the bone and the pelvic veins.

Clinical Features.

There were all the features which one associates with injury to the abdominal viscera; in addition, recent haemorrhage was escaping from the rectum. As a rule in these cases there is retention of urine, and if urine is voided pain is complained of in the region of the bladder. We have had no means of judging the degree of shock which such a wound by itself would produce, as both cases were complicated by extensive damage to the small intestine.

Treatment.

We at first proceeded to open the abdomen. The wound in the rectum was sutured and an inguinal colostomy performed; any repair of small intestine which was necessary was carried out. In both instances we further attempted to drain the extraperitoneal wound of the rectum by enlarging the entrance wound and passing a tube to the damaged wall of the gut.

Both cases unfortunately ended fatally; the shock produced by the damage to small intestine was apparently the cause of death.

Synopsis of Cases.

CASE LXI.

Cpl. H. J., Seaforth Highlanders. There was an entrance wound of the left buttock, and, in addition, there were the signs of injury to the abdominal viscera. There was no exit wound; the entrance wound was bleeding profusely. The abdomen was opened; there was a relatively small wound in the right wall of the rectum; there were six perforations in the lower end of the ileum, and the abdominal cavity contained a large quantity of blood. The wound of the rectum was sutured and a colostomy performed; the damaged loop of small intestine was resected; the entrance wound was opened up and as far as possible an extraperitoneal drainage of the rectum established.

CASE LXII.

Private S. W., Connaught Rangers. There was a small entrance wound immediately below the left buttock; great abdominal pain was complained of, and there was general abdominal rigidity. The abdominal cavity was opened; the right lateral wall of the rectum was perforated, and there were several perforations in the lower end of the ileum. The rectal wound was closed with sutures, and an inguinal colostomy was done; the damaged portion of small intestine was resected.

GENERAL REMARKS.

We are convinced that in the vast majority of cases of penetrating wounds of the abdomen operative measures offer the best chance of success. We would qualify the statement by excluding from the category uncomplicated wounds of the liver, and certain wounds of the kidney. When the wound affects the hollow viscera of the abdomen, we are satisfied that it is only as the rarest exception that a spontaneous recovery occurs.

When these cases arrive in hospital they are almost universally in a state of intense collapse. We have therefore found it advisable to wait for a period of from one to two hours, until the increased shock of the journey has subsided.

To this rule we make one exception—those cases which show evidences of rapid and progressive haemorrhage; in such cases the risks attendant on immediate operation are taken.

During the interval of waiting it is difficult to decide whether or not active stimulant measures should be adopted. These cases are generally complicated by some degree of haemorrhage, and stimulant measures in all

probability tend to increase the bleeding; we therefore limit the pre-operative stimulation to getting the patient thoroughly warm and administering 1 c.cm. pituitary extract.

During the operation every precaution is taken to minimize the degree of shock; the theatre is thoroughly heated, the table is provided with a hot-water bed; lately we have found it advantageous to operate on these cases while they are in the Trendelenburg position.

Immediately before the operation commences the administration of subcutaneous saline by a Lane's bag is begun, and it is continued throughout the operation; three to four pints of fluid are frequently given in this way. We have tried several different methods of anaesthesia. We have had good results from the use of spinal anaesthesia, but there is difficulty in obtaining the freshly prepared anaesthetic, and it would appear that this is an important detail. In two instances we have had patients collapse suddenly after the administration of this anaesthetic. More lately, and on the suggestion of a paper by Yandell Henderson, we have employed closed ether anaesthesia. The paper above mentioned adduces evidence to show that by this method of anaesthesia shock is considerably lessened.

The method has given us great satisfaction. Briefly the operative technique which we have employed is as follows:

The abdomen is opened in what would appear to be the most suitable situation, and generally in the middle line. A large incision is employed. If the abdominal cavity contains a large quantity of blood, sufficient of this is rapidly swabbed away with a long roll of dry gauze to clear the view. A systematic examination of the various viscera is now carried out. We begin by picking up the caecum and recognizing the ileo-caecal junction; we work back rapidly along the whole length of small intestine, examining not only the gut but also its mesentery. The large intestine is reviewed, special attention being paid to the various flexures. If necessity arises the stomach on both aspects, the duodenum, the liver, and spleen are examined. It is a wise precaution to palpate both kidneys, especially the left kidney, in cases of damage to the spleen. The pancreas is reviewed during the examination of the posterior wall of the stomach. The pelvic viscera are examined last, and to facilitate their examination the residual haemorrhage is more completely cleared away. The question arises whether or not the abdominal cavity should be washed out. In early cases with extensive soiling of the peritoneal cavity we have done so; in later cases, and in those which showed evidences of peritonitis we have not done so. We have found it sufficient to establish drainage by a single Keith's tube, passing into the pouch of Douglas. In special instances such as have already been mentioned we have found it necessary to drain locally or in the flanks.

We invariably close the abdominal wall with through-and-through sutures of silkworm gut, guarded where they pass over the wound junction with small pieces of capillary rubber tubing. A Doyen's handled needle is the ideal instrument for inserting these sutures.

Throughout the operation speed is an important factor, coupled with every possible avoidance of shock.

As regards the post-operative treatment, there is very little which we wish to add; it is similar to that of every other abdominal operation. Special attention is paid to the administration of fluids—for choice by the administration of continuous rectal salines and by subcutaneous infusions.

One is frequently asked regarding the prognosis of these cases. There is this fact to be recognized, that one must be prepared for repeated most bitter disappointments, but when one comes to view a series of cases, the gains seem infinitely greater than the losses. The prognosis, of course, very largely depends on the degree of the injury sustained, but an even more important factor is the length of time which has elapsed since the injury was sustained. Early operation offers the best and surest chance of ultimate success. In reviewing the statistics of the results of such operations as these it is impossible to consider the question *en masse*. Each individual case must be considered, for the chances of success depend upon so many factors that it varies enormously in different instances.

We wish to acknowledge our indebtedness to Colonel Cuthbert Wallace, R.A.M.C., for his encouragement and

advice; also to Lieutenant-Colonel Wear, C.M.G., R.A.M.C.(T.), for permission to record these cases. The illustrations are the work of Sergeant Wilson and Private Warr, R.A.M.C.(T.).

A METHOD OF TREATING GENERAL PERITONITIS WITH OBSTRUCTION, AND ITS APPLICATION IN MILITARY SURGERY.

By W. SAMPSON HANDLEY, M.S., F.R.C.S.,

Captain R.A.M.C.(T.); Surgeon with Care of Out-Patients to
The Middlesex Hospital.

My interest in the subject of obstruction secondary to peritonitis dates back for ten years. During this period I have been collecting cases in which, as the result of peritonitis confined to the pelvis, obstruction has supervened. My conclusions were presented in a Hunterian Lecture last year. I showed that the guts below the horizontal level of the symphysis were paralysed, while the bowels above, though distended, retained their contractile power. As the pelvis contains both a length of large and a length of small intestine, there are two obstructions to be dealt with, and the name "ileus duplex" was suggested for the condition.¹

The success of the treatment I adopted in cases of ileus duplex led me to attack on the same lines the more difficult problem of paralytic obstruction in cases of general peritonitis.

It must here be remarked that not all cases of general peritonitis go on to the stage of obstruction. This is especially the case in children, and I have operated upon a boy of 12 with absolutely universal peritonitis extending up to the diaphragm in whom no sign of obstruction was present. Recovery followed free drainage of the peritoneal cavity. Furthermore, in the early stages of general peritonitis peritoneal drainage is often successful in arresting the spread of the peritonitis and in preventing the onset of obstruction. There are, too, numerous cases of mild paresis of the bowel in peritonitis which can be successfully treated by subcutaneous injections of eserine, by turpentine or ammonia enemata, or by purgatives. This paper deals exclusively with cases in which the accepted modes of treatment have failed to avert or relieve paralytic obstruction of the bowels.

If there is a condition in surgery which is stamped with the word hopeless, it is that stage of a general peritonitis where, in spite of pelvic drainage, cessation of the passage of flatus and persistent foul vomit indicate that complete obstruction has supervened. The rigid abdominal muscles have been forced to yield by the pressure of fluid poured out into the paralysed intestine, and the abdomen is uniformly and tightly distended like a drum. The pulse becomes running, the extremities cold, and the patient, measuring his condition by the abnormal clearness of his faculties, only within a few hours of the end realizes with a horrible certainty that he is in the inexorable grasp of death.

This would be accepted as a true clinical picture of the later stages of general peritonitis. But in abdominal surgery typical "clinical pictures" are of pathological interest only. They imply that the surgeon's chance has gone.

Is it inevitable that cases of general peritonitis should reach the condition thus depicted? There is a preceding stage in which the obstruction is complete, but the pulse is still relatively good, and the vomit has not become offensive. The abdomen is generally distended, but it is absolutely rigid only below the umbilicus. The upper half of both recti is softer than the lower half, and above the umbilicus slight respiratory excursions of the abdomen can still be seen.

This is a stage of general peritonitis which is not recognized in the textbooks, but is known to all surgeons of much clinical experience. It is the stage of the clinical sketch, not of the clinical picture; the stage of deadly struggle, not yet of decisive defeat.

Is the problem presented by such cases really hopeless of solution? By the present methods of surgery it

certainly is. There are, however, certain indications that it may not prove insoluble. Let me tabulate these hopeful indications:

1. General peritonitis is rarely universal.
2. General peritonitis usually begins at the lower limit of the peritoneal cavity and spreads gradually upwards.
3. The persistent vomiting indicates that the stomach and upper bowel retain their contractile power to a late stage.

General Peritonitis rarely Universal.

What is meant by the term "general peritonitis"? The term is loosely used. It is quite certain—and here I speak from my own experience in the operating theatre—that in cases presenting the clinical features of general peritonitis universal peritonitis is rarely found. Any widespread peritonitis unlimited by adhesions is included under the clinical term "general peritonitis." If as a rule the peritonitis involved the upper part of the abdomen, it would avail little that its distribution is rarely universal, for in these circumstances the treatment I am about to suggest would be impossible. Fortunately, however, general peritonitis, whatever the point at which the infection reaches the peritoneal cavity, usually begins in the pelvis and spreads upwards.

In cases of general peritonitis due to appendicitis the infection of the peritoneum invariably starts in the pelvis. It is the rule, even in cases where the source of infection—for example, a gastric ulcer—is in the upper part of the abdomen, that an unlimited peritonitis is at its maximum in the pelvic region, and that it spreads from below upwards through the abdomen. This of course depends upon the fact that gravity carries most of the irritating material down to the lowest point of the abdominal cavity. Moreover, if the rupture is on the anterior wall of the stomach, the great omentum shields the small intestine. If the rupture is on the posterior wall, the contents of the stomach reach the pelvis by way of the right kidney pouch, and do not much affect the small intestine. But there are exceptions. If there is very extensive fouling of the peritoneum, as by the escape of a large quantity of stomach contents through a perforation, or by multiple wounds of the intestine, a true universal peritonitis may be set up. Wallace records death from peritoneal inflammation within twenty-four or thirty-six hours of a gunshot wound. Such cases are, however, exceptional, and it may be stated, broadly speaking, that a so-called general peritonitis is an unlimited peritonitis commencing in the pelvis and spreading gradually upwards, so as to involve a larger and larger area of the peritoneal cavity. This statement is based upon inspection of the abdominal cavity during life in a large number of cases. I am convinced that in the vast majority of cases of general peritonitis a cautious investigation of the upper abdomen would show it to be uninvaded. Among some hundreds of cases of appendicitis with peritonitis I only recollect a single one in which a true universal peritonitis, affecting every district of the peritoneum, was present.

Persistence of Contractile Power in the Stomach and Upper Bowel.

It may seem paradoxical to include the symptom of persistent vomiting among the hopeful indications. There is, of course, a last stage where the vomiting is the mere mechanical overflow along the oesophagus from the over-distended stomach and intestines, and is similar to the gush of stomach contents from the mouth which may be produced by pressure upon the abdomen of a corpse. But in the stage prior to this the vomiting is due to active contractions of the stomach and the small intestine.

That is to say, the vomiting indicates persistence of peristaltic power in the stomach and upper intestine up to within a short period of death.

We have now reached important conclusions which will guide us in attempted treatment: (1) In general peritonitis which, in spite of drainage, has produced signs of intestinal obstruction, which has reached, that is to say, a stage now regarded as hopeless, we can still rely for a time on the functional activity of the muscle of the stomach and of the upper part of the small intestine. (2) In such cases

the upper part of the abdomen, roughly speaking that part of it lying above the umbilicus, may be regarded as for some time longer free from peritonitis. In this district we may provisionally assume that surgical operations may be undertaken which postulate the power of repair, such operations, for instance, as intestinal anastomosis. The intestine in this region will be distended because of the obstruction below; it will be inflamed, if at all, only just before the approach of death.

We are now in a position to discuss the indications for operative treatment. It is fairly obvious that any treatment adopted must not involve unduly prolonged manipulation or exposure, and must not add to the shock which is already present. Any method which fails to fulfil these conditions will simply hasten death. It is for this reason partly that the emptying of the paralysed intestine by threading a tube through it has given such unsatisfactory results. Moreover, the emptied intestine still remains flaccid and powerless, and the obstruction consequently persists.

In discussing this question of treatment I must return to the subject of ileus duplex—paralytic obstruction due to pelvic peritonitis. Here, in my opinion, is to be found the key to the treatment of general peritonitis, for I found that recovery could be secured in such cases by anastomosing the suprapelvic ileum to the ascending colon, and then opening the caecum by a caecostomy.

The principle involved might be stated generally in the following terms:

In cases of peritonitis involving the lower part of the peritoneal cavity up to the level of the pelvic brim, when obstruction supervenes, it can be treated successfully by the improvisation of a shortened but complete alimentary canal above that level. The simplicity of this statement gives it the air of a truism, nevertheless I believe it represents a marked advance in abdominal surgery.

We have now to consider whether this principle, which has proved to be successful in cases of pelvic peritonitis, can be extended to the more difficult case in which the peritonitis is general.

In peritonitis limited to the pelvis, the intestinal paralysis affects exclusively the portions of gut contained in the pelvic basin, namely, the lower portion of the ileum, and the pelvic colon and upper portion of the rectum. In so-called general peritonitis, at the time intestinal obstruction supervenes, the line separating the inflamed and uninfamed districts of the peritoneum is, as we have seen, roughly a horizontal line drawn through the umbilicus. Below this line lies paralysed intestine, above it intestine which is still functionally active.

Thus in clinical "general peritonitis" the conditions are not dissimilar in kind from those present in ileus duplex, but the level separating the inflamed district of the peritoneum from the upper uninfamed portion is situated higher up. A much more considerable length of the small intestine is paralysed, and perhaps (a) the whole of the ileum may be assumed to be out of action; (b) the caecum and ascending colon will be paretic or actually paralysed, so also will be (c) the descending colon and the pelvic colon. This stage of peritonitis may be described as the stage of hypogastric ileus. I suspect that nearly all cases of general peritonitis pass through this stage, and that in many of them the stage lasts long enough to allow of hopeful surgical treatment on the lines now to be described more in detail.

The parts of the alimentary canal which are still unparalysed, and therefore available for constructing the suggested emergency alimentary canal, are the stomach, the jejunum, and probably the transverse colon, which lies on the boundary line of the inflamed district. All the rest of the intestine, small and large, is paralysed.

Is Jejunostomy a Satisfactory Treatment?

Under these conditions a jejunostomy might be tried, according to Bonney's suggestion. It would re-establish the current in the unparalysed portion of the intestine. It also might be arranged so as to cut off the reflux tide of septic material passing up to the stomach. It might thus conceivably save the patient's life, but as it would cut off the supply of fluid to the greedily thirsty mucosa of the large intestine it would probably fail, for patients with peritonitis are already starved of fluid.

Treatment by Jeuno-transverse-colostomy with Caecostomy.

If a jeuno-colostomy is made between the jejunum low down and the middle of the transverse colon, uncontaminated fluid taken into the stomach is passed along the unparalysed jejunum into an unparalysed portion of the large intestine, where it can be absorbed. But the caecum and the rest of the colon are paralysed, and there is no outlet from the transverse colon. Distension of the caecum would follow the operation, and rupture of this viscus might be expected. Here, as in ileus duplex, temporary provision must be made for draining the caecum until the inflamed large bowel has recovered its peristaltic power.

My scheme of treatment, then, is as follows:

(1) For pelvic peritonitis and intestinal obstruction (ileus duplex) consequent thereon—ileo-colostomy to the ascending colon with caecostomy (Fig. 1).

(2) For so-called "general peritonitis"—that is, unlocalized peritonitis, extending roughly up to the level of the umbilicus, with intestinal obstruction (hypogastric ileus)—jeuno-colostomy to the transverse colon, with caecostomy (Fig. 2).

FIG. 1.—Ileus duplex (paralytic obstruction secondary to pelvic peritonitis). Treatment by ileo-colostomy and caecostomy.

In all cases pelvic drainage must be provided.

The advantages gained by such an emergency alimentary canal—consisting of stomach, jejunum, transverse and ascending colon and caecum—are numerous. The normal intestinal current is restored, vomiting ceases, the stomach is not fouled by a reflex of septic intestinal fluid, and becomes once again a clean vessel apt for the digestive processes. For it is clear that fluid regurgitating from the lower intestine will rather pass through the jeuno-colostomy opening into the colon than face the tortuous and active resistance of the jejunum. The jejunum itself receives only the uncontaminated products of digestion from above, and intestinal digestion and absorption can take place unhindered. It is true that the colon will still contain septic fluid regurgitated from below, but the absorptive power of the colon for aught but water is negligible. The colon can perform its important function of water absorption even when its contents are laden with bacteria—their normal condition.

Thus provided with clean food and fluid—the things he most requires—the prospects of the patient's fight with his peritoneal infection are vastly improved.

It may be objected that the steps taken to re-establish the intestinal current will be defeated by the continued upward spread of the peritonitis. In a proportion of cases where the peritoneal infection is virulent this objection is doubtless valid. But it omits to take into account the probability that in many cases intestinal paralysis is the main factor determining the continued spread of the peritonitis. It is well known that distension of a hollow viscus interferes with its blood supply, impairs its nutrition, and renders its walls pervious to the bacteria within. There is every reason to hope that in many cases the relief of the distension in the upper gut will turn the scale in the patient's favour by arresting the further upward spread of the peritonitis. Strong evidence in favour of the supposition is provided by the success of similar treatment in arresting the upward spread of pelvic peritonitis in cases of ileus duplex.

Technique of Jeuno-transverse-colostomy.

The operation of jeuno-colostomy can be quickly and easily carried out without evisceration of the intestines and practically without shock. An incision 4 in. long and extending down to a point 1 in. below the umbilicus, is made through the middle of the right or left rectus muscle. The lower border of the transverse colon is exposed and identified and pulled forward. The great omentum is torn through just below the gut, and two fingers are introduced through the rent to seek for a suitable coil of jejunum. The coil selected, like all the small intestine, will be distended, and may be congested, but it should not have lost its lustre or its resilience. It is drawn forwards into the wound, where it lies just below the fold of transverse colon, which has also been withdrawn. Clamps are applied to the two selected pieces of gut, and a lateral anastomosis is made in the ordinary way. The anastomosis can be strengthened subsequently, if desired, by sewing down the great omentum to the surface of the jejunum. The bowel is returned, the incision is sewn up, and a caecostomy is performed in the ordinary way through a separate incision. It is well to tie

FIG. 2.—Hypogastric ileus (paralytic obstruction of early general peritonitis). Treatment by jeuno-transverse-colostomy and caecostomy.

a Paul's tube in the caecum, but experience may show that a large rubber catheter does equally well.

A Case where the Treatment was Successfully Applied.

An opportunity was lately presented to me, in a case now to be described, of testing the validity of the chain of reasoning I have laid before the reader.

Miss H., aged 30, had for some months complained of vague abdominal pain at intervals, but had not sought medical advice.

On December 29th, 1915, she was taken ill with what was supposed to be a chill on the liver. She kept at her work, and did not consult a doctor. The following day vomiting began, and was repeated soon after she took a purgative. The abdominal pain, of a colicky character, was situated in the lower part of the abdomen. On December 31st she went to town as usual, but was sick and ill, and the pain persisted. On January 1st she was worse, and was then first seen by Dr. A. J. Hogg, of Ealing. He found that she had general severe abdominal pain and tenderness, worse on the left side. There was little movement of the abdomen on breathing. The vomiting had been bilious, and the temperature was 100°, the pulse about 90. At 6 p.m. on the same day the pulse was quicker and the temperature higher. There was great pain in the lower part of the abdomen, and she lay on her back with her legs drawn up. On this day for the first time there was pain on micturition, and in the evening Dr. Hogg asked me to see her with him with a view to operation. About 10 p.m., when I saw her, her pulse was 120, her colour good, and she did not appear to be in much distress. There was slight general abdominal distension, and the abdomen moved to a certain extent with respiration. There was no true abdominal rigidity. In the right iliac fossa an indefinite resistance could be felt. On pelvic examination there was extreme tenderness in the region of the pouch of Douglas, with fixation of the uterus, thickening of the right utero-sacral fold, and some resistance of the right broad ligament. The periods were regular, the last one having ceased a fortnight previously. The patient's statements as to the passage of flatus were rather vague, but she did not appear to have passed it more than once in the preceding twenty-four hours.

In view of the early colicky hypogastric pain, of the signs on the right side of the pelvis, and of the pain on micturition, together with the absence of abdominal rigidity and the presence of resistance in the appendix region probably due to swollen ileo-colic glands, we arrived at the conclusion that the

patient was suffering from pelvic appendicitis. It was thought, in view of the continued vomiting, that intestinal obstruction was likely to complicate the case.

First Operation.

Immediate operation was decided upon, and a median hypogastric incision was made. On opening the peritoneum a certain amount of clear fluid escaped. The omentum was adherent in the pelvis, and on separation it was found to be sloughing at its tip. The coils of small intestine, which now came into view, were rather congested, but had not lost their lustre. The pelvis was packed off from the rest of the abdomen, and on passing the hand down into it, some ounces of thick pus escaped, and a mass was found which on extraction proved to be a swollen and gangrenous appendix containing two large concretions. There was superficial sloughing of a portion of the caecum near the base of the appendix. All the intestines in the lower abdomen were distended by flatus and rather congested, but there were no areas of oedematous, collapsed, and deeply-congested intestine such as are seen in typical cases of ileus duplex. The condition appeared to be general paresis of the pelvic and suprapelvic intestines without actual paralysis, and it seemed likely that eserine and pituitary extract would maintain peristalsis in the damaged gut, but it appeared safer to tie a catheter into the caecum and bring it out through the median wound. The pelvis was drained by two large tubes.

After the operation the patient was placed in the Fowler position, saline was administered subcutaneously to the extent of about six pints for the first twenty-four hours, and injections of eserine salicylate were given every six hours in order to produce intestinal contractions. The catheter, either because it was blocked, or because there were no contractions in the intestine, did not act. Turpentine enemata were given, but only produced a little faecal-stained fluid, and no flatus passed per anum. A purgative failed to act, and forty-eight hours after the operation the condition of the patient was most alarming. The abdomen up to the umbilicus was rigid, hard, and tensely distended like a football. Above the umbilicus the distension was not so marked; rigidity was absent, and there was some abdominal movement with respiration. The pulse had risen in frequency. The patient was not sick, but was troubled by constant feelings of nausea which made her unwilling to take nourishment.

Second Operation.

Since I have never seen a patient recover from a similar condition of general peritonitis with complete obstruction, I told the friends that recovery was improbable in any circumstances, and certainly impossible unless something further was done. It appeared certain that the peritonitis had extended as high as the level of the umbilicus, and that the whole of the ileum and the lower colon were suffering from paralysis the result of the peritonitis. The condition of the abdomen above the umbilicus showed, however, that the upper part of the small intestine—say, roughly, the whole of the jejunum—was still capable of normal peristalsis. Though the ascending and descending colon were probably paralytic, the transverse colon lying at the upper limit of the peritonitic area might be presumed still to retain its contractile power. A lateral anastomosis between the lower jejunum and the transverse colon seemed, therefore, to be the rational method of treatment if combined with a caecostomy to afford a free exit for the contents of the large intestine.

The friends of the patient consented to further operative measures, and through an incision 4 in. long situated $1\frac{1}{2}$ in. to the right of the middle line and extending downwards to an inch below the umbilicus, I reopened the abdomen.

The incision exposed the lower border of the transverse colon, which was distended by flatus and apparently not inflamed. Just below the transverse colon I tore through the great omentum and thus obtained access to the upper small intestine. The first coils it presented (belonging probably to the upper ileum or lower jejunum) were too much distended and inflamed to permit of their use for the lateral anastomosis, a proof that the peritonitis had actually extended up to the umbilicus. Two fingers introduced in a direction upwards to the left succeeded in withdrawing a higher coil, which though distended was not inflamed. This coil was brought forward in the opening in the great omentum and clamped. A clamp was next applied to the closely adjoining portion of the transverse colon, which also had been brought out into the wound. The area was packed off, and a lateral anastomosis was made in the usual way. Since the small intestine, owing to distension and slight oedema, did not hold stitches well, a portion of the great omentum was drawn down over the suture line so as to strengthen it. The bowel was returned and the abdominal incision was sewn up. The caecum was next sought in the original wound at the point where the catheter was tied in it, and here a Paul's tube was inserted.

After-History.

The patient bore the operation well, and her pulse at the end of it was about 120. It should be added, as indicating the virulence of the bacteria present, that the whole of the surfaces of the original incision were at this time covered by a superficial grey slough. The result of this operation was most satisfactory. It was followed by the administration of a purgative, and the following day the colotomy had acted well. A certain amount of fluid material together with flatus had also passed by the anus. The lower abdomen, though still tender, had lost its tension, and the rigidity was less marked. Three days

after the operation a tender swelling developed in the right iliac region. There was also some suppurative of the incision of the second operation. The right iliac swelling was opened two days later, and proved to be an abscess in the abdominal parietes, probably due to extension of infection from the region of the second operation. No leakage took place at the lateral anastomosis. When the Paul's tube came out there was a considerable escape of semifluid intestinal contents from the caecostomy, and the bowels also continued to act per anum. The patient's temperature fell, the wound assumed a healthy aspect, and her appetite returned. For some time after the operation a fluid action of the colotomy wound followed each meal. Nutrition rapidly improved and strength returned. The caecostomy wound has contracted, and will no doubt soon close.

The anaesthetics were given by Mr. Herbert Charles. I am indebted to Drs. A. J. Hogg and W. B. Stanford for their unremitting care in the after-treatment, which alone rendered recovery possible.

Conclusion.

The condition of a patient suffering from general peritonitis which is spreading upwards through his abdomen may be compared with the predicament of a house invaded by a rising flood. The householder can only survive the crisis if he retires upwards to the first floor. There he must improvise arrangements for carrying out in a rudimentary fashion the primary needs of existence. There he must cook, eat, and sleep until the flood subsides. The essence of this paper is a suggestion that a similar policy may save patients attacked by the rising flood of a general peritonitis.

Treatment of Gunshot Wounds of the Abdomen.

Colonel Cuthbert Wallace² tells us that men shot through the abdomen die mainly from one of three causes: haemorrhage, peritonitis, or intestinal obstruction following peritonitis. Most of the deaths from haemorrhage will take place before the hospital is reached. In the survivors an early operation for suturing or resection of the bowel may avert the dangers of peritonitis and obstruction. It is a triumph of surgery, and still more of organization, that operations of this character are now relatively successful. In wounds of the small gut, when the patient arrives in a condition that permits operation, Colonel Wallace³ and his colleagues have secured about 50 per cent. of recoveries, a remarkable result when it is borne in mind that the mortality of expectant treatment is 100 per cent.⁴ It is an unsolved problem how many of the residual cases die after operation from the mere intensity of the peritoneal inflammation. It seems likely that some of these cases are capable of recovery from the peritonitis alone, but that their chance is spoilt by the onset of obstruction. To such cases the method suggested in this paper is clearly applicable, and possibly with success.

But, though its hypotheses have been stated dogmatically for the sake of emphasis, my paper is to be regarded as suggestive only. I hold no brief for my conclusions, and only ask that they should be tested. It is unnecessary to offer a defence against the charge of premature publication, for at the present crisis many rules, usually salutary, must be suspended in the public interest for the duration of the war.

THE United States Bureau of the Census is, we learn from the *Boston Medical and Surgical Journal*, about to issue a monograph on deaths from cancer in the United States during the year 1914. It will consist of tables showing the deaths from cancer, according to the site of the disease, age, sex, colour, nativity, and marital condition, for the registration area, the several registration States, and the usual subdivisions. The seven titles for cancer in the international list of the causes of death are subdivided into twenty-nine headings referring to the exact site of the disease. It is proposed to tabulate separately the returns in which the diagnosis was "reasonably certain" and those in which it was "uncertain." In arriving at this distinction, a report is classed as "certain" if the diagnosis was confirmed by microscopic examination of tissues, by surgical operation, or by autopsy. All cases of internal cancer in which the diagnosis was based on clinical observation alone are classified as "uncertain."

"TRAUMATIC GASTRIC ULCERS."

BY

T. R. ELLIOTT, F.R.C.P., F.R.S.,

TEMPORARY MAJOR R.A.M.C.,

AND

HERBERT HENRY, M.D.,

TEMPORARY CAPTAIN R.A.M.C.

SURGICAL work with the army in France during the last six months has proved conclusively the value of early operation in gunshot wounds of the abdomen. In his admirable summary¹ of the experience gained by the careful observations of several workers in one army area, Colonel Cuthbert Wallace states the clear rule that a perforating wound of the intestine cannot be healed by spontaneous closure, and that such injuries of necessity must be treated by operative procedures at as early a moment as is possible. With regard to wounds of the stomach there is still doubt, because there are some grounds for the belief that such lesions are capable of cure by natural processes, and because it is certain that the wounds will often be found to lie in areas which are difficult for the surgeon to reach.

Surgeon-General Sir George Makins has discussed this latter question briefly,² and his conclusion is that on the whole it is unwise to open the abdomen in cases in which only the stomach is supposed to have been wounded. The advice is confessedly a conservative choice, in view of the lack of sufficient pathological evidence to justify a reasoned conclusion one way or the other. Colonel Cuthbert Wallace admits the probability that some stomach wounds may heal without operation, but none the less he decides that "it is wise to make no exception in the case of the stomach, but to operate on principle," the principle being that any gunshot wound of the intestinal tract is less likely to be fatal if repaired by immediate surgery than it is when left to rest and nature.

With perforations of the intestine the chief danger to life arises in the development of peritonitis. In the case of stomach wounds, peritonitis is perhaps rather less to be dreaded since there is undeniably a chance that the aperture may be sealed by adhesions, and since the gastric contents, which may leak out before such adhesions can be cemented, are not very septic. But here a fresh risk appears. The injured tissues are liable to be eroded by the gastric juice, and if a vessel is opened up in this process the wounded man may be in serious danger of losing his life by secondary haemorrhage from what is practically a traumatic gastric ulcer. It is this particular point of ulcer formation which the cases described in this paper have been chosen to illustrate.

Haematemesis and melaena are not often seen as an immediate result of wounds of the abdomen, for the early bleeding in these cases is chiefly from vessels which leak into the peritoneal cavity or into the retroperitoneal tissues. But these symptoms do occasionally appear about the second week, and at that date they are generally to be interpreted as evidence of an extending ulcer in the stomach or duodenum. This ulcer may be developed in a previously healthy mucous membrane as the result either of direct perforation or of contusion, or even, as in the rare case described by Captain Kelly, as the outcome of septic processes which are active at a considerable distance elsewhere in the body. To the naked eye such an ulcer looks very similar to the ordinary non-traumatic acute perforating ulcer of civil life. It commences in the internal mucous membrane, and may extend therein over a much wider area than is shown by the thin, sharply-cut edges of the external perforation. It may have the same

result in leading to perforative peritonitis, or to sudden haemorrhage when a vessel is eroded; but it is more liable than is the non-traumatic ulcer to form a gastric fistula, since it may open up the track of the injury first produced by the missile.

CASE I.

No. 229. Under the care of Captain A. Bradford.

December 29th, 1915. Shell wound; a tiny hole over the seventh left intercostal space in the anterior axillary line. No abdominal pain or vomiting, and in consequence the patient was evacuated to the base as being simply wounded in the chest.

Third day: Arrived at base hospital in Boulogne. Vomiting of green fluid commenced and continued until the fifth day.

Sixth day: Melaena appeared with diarrhoea.

Seventh day: Very blanched and thirsty. Moribund and semi-delirious. Pleurisy in left axilla, and physical signs of left haemothorax of moderate size. Nothing abnormal found in abdomen, which was soft and moved freely. Gastric ulcer diagnosed, and food withheld. Patient too ill for operation.

Ninth day: Died.

Post-mortem Examination.

Left haemothorax containing 30 oz. of fluid defibrinated "blood"; lower lobe partly collapsed and coated with granular fibrin. Hole through left diaphragm 5 mm. in diameter. Some thin bile-stained fluid free in the peritoneal cavity, but no evidence of peritonitis.

On the anterior wall of the cardiac fundus of the stomach a round hole 2 cm. in diameter, and nearer to the pylorus on the posterior surface a much smaller hole about 8 mm. across. The stomach contained very little fluid, but a small flake of shell, about 5 mm. long, was found within it, embedded in mucus. Between the stomach and the spleen was a localized collection of several ounces of viscid bile-stained fluid, which did not appear to be purulent and of which the reaction was not tested. This pool of fluid was contained by light adhesions springing from the anterior surface of the stomach, and an outlet from it appeared to be spreading forward by a narrow track along the anterior surface of the left lobe of the liver. The outer wall of the cardiac fundus, where it was submerged in the pool, had been partly digested away, but showed no evidence of gangrene or other injurious process. The perforating ulcer was circular in outline with smooth edges, and it was very much larger than the holes made in the chest wall or in the diaphragm, which corresponded roughly to the size of the piece of shell. All around it the peritoneal coat had vanished over an area nearly 10 cm. across, and the

FIG. 1.—Stomach showing traumatic gastric ulceration (Case I in text). A. The anterior perforation. E. The terraced edge limiting the spread of the external ulceration, which had denuded the peritoneal coat. P. The posterior perforating ulcer. (Specimen in War Office collection.)

circular muscle fibres of the stomach wall beneath were naked and transparent. A white terraced edge marked the transition from this external ulceration to the normal peritoneum at the attachment of the adhesions. (See drawings; specimen in War Office collection.) The posterior ulcer was closely limited by adhesions, and it did not display a similar external spread. Apparently the haemorrhage had been derived from vessels underlying this ulcer.

The patient died simply from gastric haemorrhage, which commenced about the sixth day. The anterior perforation, had time allowed, would doubtless have led to a subphrenic abscess. The posterior ulcer may have developed out of a perforation or only from an area of contusion in the stomach wall, for the momentum of the small shell fragment was spent when it reached the back of the abdomen. The destruction of the outer wall of the living stomach by the gastric juice, which had escaped from its interior, was a very remarkable fact in this case.

CASE II.

No. 16,502. Originally under the care of Captain R. Charles, who kindly transferred to us the full clinical notes of the case.

January 4th, 1916. Wounded by a bullet with slightly deformed nose, which entered the left epigastrium close to the subcostal triangle. Abdomen opened five hours later; free blood swabbed out of the peritoneal cavity; hole through left lobe of liver sutured and packed. The bullet had subsequently passed through the left sac, and it was found close to the duodeno-jejunal flexure, half in the less sac and half projecting through into the greater peritoneal cavity. Slight bleeding near tail of pancreas. A branch of the coronary artery on the less curvature of the stomach had been wounded by the missile, and this required ligature. At the time there was certainly no perforation of the stomach. Gauze drains were passed down to

the liver wounds, and also to the pancreas through a fresh hole in the mesocolon, while a tube was placed in Douglas's pouch.

Eighth day: Abscess opened in anterior abdominal wall, from which a considerable quantity of clear fluid and thin pus came away.

Tenth day: Again evacuation of pus and of at least one pint of clear fluid. An accident prevented the reaction of this fluid from being tested.

Twelfth day: Severe haematemesis and melaena.

Twenty-eighth day: Chest explored by needle but nothing found. Transferred to base hospital at Boulogne, since the general condition had improved.

Thirty-sixth day: Died.

Post-mortem Examination.

Empyema on left side and purulent pericarditis. Small collections of pus were loculated everywhere between the coils of intestine. No intestinal obstruction.

A blind fistula with yellow-stained walls led down from the anterior surface of the left lobe of the liver into its substance. Close to this a fistulous track ran below the lower edge of the liver and through the gastro-hepatic omentum to a gaping circular ulcer situated on the less curvature of the stomach, half-way between the pylorus and the cardiac orifice. There was no obvious inflammation around this, and no cicatricial deformation had been produced. Within the stomach the ulcer extended over a wider elliptical area along the less curvature, and was much larger than the perforation on the external serous surface. The silk ligature, which had been knotted around the bleeding vessel at the operation, lay in fibrous tissue on the outside of the stomach wall at the edge of the perforation. Bleeding had ceased, but the ulcer remained open and was presumably discharging gastric juice from the fistula. No evidence of fat necrosis was seen in the pancreas. (Specimen in War Office collection.)

In this case death was the result of a widespread and hopeless infection of the serous membranes. At the spot where the bullet had injured the stomach, whether by contusion or through interference with the blood vessels, an ulcer had formed and perforated some time before the sixth day, while its further spread was evidenced by haemorrhage on the twelfth day. The ulcer remained open and showed no signs of healing when death occurred on the thirty-sixth day.

CASE III.

No. 9,399. Under the care of Captain W. H. Oliver.

February 6th, 1915. Bullet wound high up in the left axilla and no exit. Slight haemoptysis, but no vomiting.

Tenth day: Vomiting suddenly began and about 1½ pints of blood were brought up. This was, by mistake, reported as haemoptysis.

Twelfth day: Abundant melaena. Signs of small effusion in left chest. No previous notes had been made of chest condition.

Sixteenth day: Melaena ceased.

Eighteenth day: Pain in epigastrium when food was swallowed. No rigidity over stomach. The patient stated that he had never suffered from indigestion before receiving this wound.

Thirty-first day: Temperature rising to 102°. Physical signs of large collection of air and fluid in left chest. Aspiration removed 35 oz. of yellowish grumous brown acid fluid, which smelt like bitter vomit, and also much air. The manometer readings proved that an open leak existed within the pleural cavity.

Thirty-third day: Rib resected. Acid fluid and "coffee grounds" deposit of altered blood escaped.

Thirty-fifth day: Clotted milk seen to be discharged from the empyema tube shortly after food had been taken by the mouth.

Thirty-sixth day: Transferred to England in very bad condition. Later history unknown, but it seemed unlikely that he would recover except by the help of unusually successful plastic surgery.

Here the only certainty is that the man bled from a traumatic gastric ulcer on the tenth day, and that some time before the thirtieth day the extension of the ulcer established a direct fistula between the stomach and the pleural cavity. The exact path of the bullet was never determined.

CASE IV.

No. 1,226; T. Under the care of Captain A. Bradford.

May 16th, 1915. Wounded by shrapnel ball, which entered the left chest at the seventh space in the posterior axillary line, and finally lodged beneath the skin over the fifth right costal interspace just below and internal to the right nipple. Patient felt a "smack" in the epigastrium. No vomiting. Slight haemoptysis on the second day.

Seventh day: Fairly well. Slight epigastric pain. Left haemothorax of moderate size with pleural friction at its upper level and over the pericardium. Pleural friction also heard over the right base. Temperature 101°.

Fifteenth day: Profuse haematemesis, followed by melaena for two days. Patient states that he had never before suffered

from dyspepsia. The haematemesis came on abruptly with a feeling of nausea, as though he were "sea-sick." Very blanched. Temperature fell from 102° to 97°.

Seventeenth day: Septic haemothorax on left side, which was found to be infected with a streptococcus and a small bacillus, drained by resection of a rib. No evidence of gastric contents in this purulent blood, which was not acid in reaction. The presence of contralateral pleurisy on the seventh day makes it fair to conclude that the haemothorax had been infected at the time of the original wound.

Twenty-seventh day: Solid food allowed.

Forty-fourth day: No further gastric trouble and empyema cavity now very small. Transferred to England. Subsequent history unknown.

The course taken by this ball was so close to the stomach that it probably injured its wall by contusion, if not by actual perforation. The complete recovery from the ulcer that subsequently formed is the remarkable fact in this case, inasmuch as these injuries, so far as we have been able to observe them, have been generally fatal.

These particular cases illustrate the manner in which such traumatic gastric ulcers develop. In all four of them the missile either went through the stomach or so close to it as to cause direct injury to its wall, though it should be remarked that in Cases I and III there was no reason at first to believe from the position of the entry wound that the stomach would be likely to lie in the subsequent path of the missile. The ulcer revealed itself by haematemesis and melaena on the 6th, 10th, 12th, and 15th day respectively in each. One patient died directly from the haemorrhage; only one made a complete recovery. The cases suggest the clinical interpretation that must, with a slight reservation to be discussed later, be made of these symptoms of bleeding when they appear in the second week after a wound, and they also show the unfavourable course that may be taken by an injury of the stomach when it has not been repaired by the surgeon. But they are in themselves too few to serve as a basis for a forcible argument in favour of early operation on supposed wounds of this viscous.

A consideration of the general mass of statistics out of which these cases were chosen throws more light upon the disputed point. Taking the *post-mortem* records in the first place, examinations have been made by us on 100 consecutive cases of death at the base hospitals from wounds penetrating the chest wall. In 17 of these the missile, whatever its point of entry, had passed in its course through structures in the right base of the chest. Only eight examples were met with of a similar track through the left base. Therefore, since the incidence of wounds on either side of the chest is probably equal, it may be concluded that the left base is a more vital spot, and that the preponderance of fatal chest wounds on the right side met with at the base is due to the fact that men with wounds on the left side show grave symptoms early and die close to the fighting line. Kidney and colon are almost equally balanced on either side, so that the difference in fatality must depend on the contrast between the liver on the right and the heart, stomach, and spleen on the left.

Of the 17 fatal cases on the right side, 11 had haemothorax, and in 9 of these death was chiefly caused by the infection of this blood; 3 had wounds of the colon, and all 3 died from the resulting septicaemia; 12 had wounds of the liver, of whom 5 died of haemorrhage from the liver; there were 7 harmless liver wounds.

Of the 8 fatal cases on the left side, 5 had haemothorax with 3 septic deaths in consequence; 2 had liver injuries, of which one died from secondary haemorrhage. There were no cases of wound of the heart, and only two of actual wounds of the stomach. Of these two stomach injuries, one died of peritonitis consequent upon the perforation, and the other from gastric haemorrhage. (Case 1). A third died of general peritonitis, and his stomach was full of blood, though no actual injury to this organ was found. So the only stomach wounds that were seen in this group were in themselves fatal, and no example was met with of a relatively harmless injury to the stomach, although this might have been fairly expected to occur in a series where chest wounds in general were being investigated. There were in the series, it should be remembered, seven examples of harmless liver wounds where death was due to other causes.

Post-mortem examinations at the base of fatal wounds penetrating the abdomen were not made by us as systematically as those of the chest. In a total of twenty-five

consecutive cases there were four instances of stomach wound, which gives six altogether when we include the two already referred to under wounds of the chest. Out of the entire six five had died as the direct result of the gastric lesion, three being from haemorrhage and two from peritonitis. The single exception died from general peritonitis caused by intestinal perforation, and in this there was discovered an actively spreading gastric ulcer in relation to a slight contusion of the stomach. Once more in the fatal abdominal, as in the fatal thoracic, wounds there was no example observed of a harmless wound of the stomach.

So far, then, as can be argued from *post-mortem* evidence derived from cases of death in men who survived long enough to be transferred to the base, a gastric wound is serious and likely to be fatal. The conclusions from the indirect evidence of survival cases is of a similar nature.

In dealing with wounded men who survive, it is rarely possible to be certain that any particular organ has been hit, even though the apparent path of the missile crosses the region in which this organ lies. *Post-mortem* evidence alone gives the sure knowledge. Still, it is permissible to make rough generalizations which depend on the assumption that the path of an in-and-out missile can be indicated by the straight line connecting the points of entry and of exit. In a series of 365 non-fatal chest wounds, recorded by one of us, the number of in-and-out wounds was tabulated. Survivors from such wounds in the upper two-thirds of the thorax were numerous. In the lower third they were relatively few. Excluding surface tangential wounds, there were twelve penetrating wounds of the right base through the liver area, and of these three actually developed biliary fistulae.⁶ Through the left base, on the other hand, there were only six survival cases noted. From this fact again emerges the same deduction as that already arrived at by *post-mortem* evidence—namely, that the left base is twice as fatal a target for a penetrating wound as is the right base of the chest.

Of the six survivors the details were as follows: Two showed no symptoms beyond those of a simple lung wound; one had a haemothorax infected with *Bacillus coli*, that may have come from the splenic colon; three exhibited symptoms of epigastric tenderness and vomiting or pain after food, which suggested injury to the stomach. All these three recovered, but one (Case IV) nearly lost his life from a spreading traumatic ulcer. The other two showed no development of other untoward symptoms while in France, and their subsequent history was not ascertained, though it was reported indirectly that one of them had developed a hernia of his stomach through the diaphragm into the pleural sac.

Summarizing the whole of these facts, one sees that wounds of the left base of the chest are twice as fatal as those of the right; that among men wounded in the thorax or abdomen who survived long enough to reach the base hospitals in France and there died, only six examples of gastric injury were found by us, while five of these injuries were the direct cause of death; and, finally, that in survival cases there were only three who showed symptoms which might be ascribed to stomach injuries, and that of these the only one who could unhesitatingly be accepted as a case of gastric injury nearly died from that injury. These figures were obtained from the study of a considerable number of wounds of the chest (total 465) and of the abdomen (total 25), and they demonstrate that the majority of men who have been shot in the region of the stomach die before they reach the base hospitals, and that those who do reach the base with stomach injuries generally succumb to their wounds. The conclusion seems clear, and it is this, that an operation at the earliest possible moment gives the best chance of recovery from a stomach wound, so that laparotomy should be undertaken when the track of the missile suggests the probability that this organ has been wounded. If abdominal exploration reveals a perforation or a bruise of the stomach, it may be judged by the surgeon that the best procedure is to invaginate the wall over all the area of injury, so as to lessen the chance of later perforation if an ulcer forms.

Secondary haemorrhage from a later erosion by the gastric juice will occur only in special areas where the larger vessels lie—that is, chiefly along the less curvature

and from the posterior wall if this becomes adherent to the underlying solid organs. Here it would be peculiarly difficult for the surgeon to gain access to the injury. We are not aware of any attempt that has been made in France to deal with such an ulcer by immediate operation during the bleeding. It is probably best at this later stage to treat the haemorrhage on expectant lines by the routine measures which are adopted for profuse bleeding from non-traumatic gastric ulcers in civil life. But the danger of ulceration should always be borne in mind where a stomach wound is suspected or known to exist; and the diet, even after operation, should be very strictly guarded in such a way as will both minimize the secretion of gastric juice, and soak up that which may be discharged into the stomach. It is most necessary to forbid categorically the use of meat extracts, such as bovril, for these, in the absence of explicit orders to the contrary, are likely to be given to the wounded man as an early restorative, and they will evoke an abundant and active secretion, which finds nothing but the half-dead gastric wall to feed upon.

At the outset of this paper we mentioned the possibility of gastric or duodenal ulcers occurring when the viscous was not directly injured by a missile, but where its mucous membrane had suffered some local devitalization through the indirect action by the blood stream of septic processes elsewhere in the body. The classical example of such a lesion is the duodenal ulcer that has occasionally been reported in civil practice as a consequence of widely-spread cutaneous burns. But in the last few years pathological work on the nature of ulcer formation has tended more and more to emphasize the probability that many acute gastric ulcers may have a similar origin in various poisonous and infective processes which affect the body in general and only indirectly injure the stomach.

With these views in our mind, we have repeatedly examined the inner surface of the stomach and duodenum at the autopsies of death from severe sepsis, and especially when the skin surface had been widely destroyed by multiple shell wounds. No examples of such acute ulceration were discovered. The sole instance we are able to relate is that for which we are indebted to the clinical diagnosis of Captain Kelly, who called our attention to the importance of the case (No. v). Nor have we observed in the wards, during an experience of sixteen months, any patient who showed, during the recovery from wounds, symptoms which could justify the diagnosis of such an ulcer formation. The very few cases of haemorrhage from acute gastric or duodenal ulcers that we have met with among unwounded soldiers were of the ordinary type seen in civil practice, and, with one exception, all recovered.

CASE V.

No. 5,834. Under the care of Captain Fitzmaurice Kelly, who had made a complete diagnosis of the nature of the lesion in the patient and kindly gave us his clinical notes of the case to complete the series of these ulcers.

January 18th, 1916. Severely injured by multiple shell wounds, in the left orbit, right upper and fore-arm, right groin close to the femoral vessels, left scrotum disorganizing the testicle, and in the right leg with compound fracture of the tibia.

Third day: Admitted to base hospital. General condition very good but groin and leg wounds suppurating with a very foul infection. Wounds cleaned under an anaesthetic, and left eye excised.

Sixth day: Left testicle removed, right groin opened more freely, and fragments of tibia partly removed.

Eighth day: Slight haematemesis occurred, and was followed by profuse melaena.

Tenth day: Patient died, after repeated haematemesis and melaena. The wounds remained in an intractably foul condition until the end. There was no extensive sloughing or destruction of skin surfaces.

Post-mortem Examination.

External wounds as described above, and extremely foul. The internal organs were all utterly blanched by the haemorrhage. Slight recent pleurisy over base of left lung. No endocarditis. Stomach dilated and its inner surface covered with a thick layer of inflammatory mucus. Just beyond the pylorus lay an acute duodenal ulcer, 2 cm. in diameter, with sharply cut clean edges, which had eroded one of the pancreaticoduodenal vessels. The intestines were filled with melaena. There was no peritonitis nor any evidence of injury to the abdominal organs. In connexion with the groin wounds there was some retroperitoneal haemorrhage which had extended up to the brim of the pelvis, but this was well drained, and its upper area was free from obvious sepsis.

Death was caused directly by the duodenal haemorrhage, commencing on the eighth day, and in this case the ulcer was certainly not caused by a wound near to the duodenum. Though the ulcer was large and deep, its appearance was that of a recently formed and acute one, and this opinion was confirmed by microscopic examination. There was no scarring or deformity around it, and the base was formed by soft pancreatic substance. Unfortunately the patient was too ill to be able to give any reliable answers on the question whether he had previously suffered from indigestion of such a nature as would have indicated the presence of an old ulcer. It is unlikely that he had been a dyspeptic, for he was a well-built soldier, 19 years old, enlisted a year back, and with four months' continuous service in France.

Summary.

1. The evidence related in this paper negatives the assumption that wounds of the stomach are less likely to be fatal than wounds of any other part of the intestinal tract.

2. A perforation or a contusion of the stomach wall by gunshot wounds is liable to be followed by the development of a spreading gastric ulcer, which in certain anatomical positions will erode vessels and determine a fatal issue from secondary haemorrhage.

3. Haematemesis and melæna occurring in the second week after a wound are generally to be regarded as the outcome of such a traumatic ulcer. These symptoms are very rarely due to haemorrhage from a non-traumatic ulcer produced indirectly as the result of septic wounds elsewhere in the body.

4. If a stomach wound has not been repaired by operation within the first twenty-four hours after the injury has been received, or if there is reason to suspect the possibility of such a wound being present, the diet should be rigidly controlled on such lines as will lessen the active secretion of free gastric juice.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INFECTIOUS JAUNDICE.

WE desire to call attention to some peculiar bodies, to which our laboratory assistant, Mr. Mann, drew our notice, in the urine of a case of jaundice with albuminuria, from Mudros.

On examination of the sediment with a low power the first thing that struck us was the presence of numerous light yellow-greenish bodies, circular or pear-shaped in outline, and of a markedly granular appearance. On examination with a $\frac{1}{2}$ in. it was seen that there was no marked differentiation of endoplasm or ectoplasm. The nucleus, usually relatively large, was easily seen. The size of the bodies varied from 8μ or less to 33μ or more, probably averaging about 20 to 25μ .

When carefully watched for some time, protrusion of a pseudopodium could be observed. This relatively clear protrusion contrasted markedly with the semi-opaque granular endoplasm. These bodies were totally unlike *Endamoeba coli* or *Endamoeba histolytica*.

No cystic forms were seen in the urine. In the faeces cysts of *Endamoeba coli* were seen.

We have named it provisionally *Amoeba urinae granulata*.

A. B. WARD, Lt.-Col. S.A.M.C.,

A. E. COLES, M.D.,

A. R. FRIEL, Capt. S.A.M.C.

South African General Hospital,
Mont Dore Military Hospital, Bournemouth.

THE late Dr. Isaac Ott, of Easton, Pennsylvania, left money for the endowment of a new chair of physiology at the University of Pennsylvania to be known by his name. Dr. Ott was known to the scientific world by his researches on the physiology and pathology of the nervous system.

Rebiews.

SURGERY IN WAR.

WE have received within the last few weeks copies of two manuals of war surgery, the one in English and the other in French. They are, we believe, the first written in either language which are frankly based upon experience gained during this war. Some other handbooks which were published a year or more ago might be more properly described as attempts to apply opinions formed before the war to the new conditions. Such books are now out of date; their places will quickly be taken by such volumes as those now before us.

The English volume, *Surgery in War*,¹ is largely the work of Major HULL, who has seen the present campaign through from the beginning to the present time. He has been assisted by Colonel H. M. W. Gray and a number of other officers on active service, most or all of whom, it would appear, have been serving in France. The subject has therefore been dealt with more as regards surgical work there than in the other spheres in which our army has been and is now engaged.

In a preface which Sir Alfred Keogh has written for the book he states that "there comes a time in a long campaign like the present one when it is profitable to take stock, as it were, of the surgical position, to apportion values to various methods of treatment and to obtain some appreciation of their results." This, we venture to think, the present volume does in a very creditable manner. The circumstances of the present war have made necessary the reconsideration of most of our ideas on military surgery. The South African campaign was carried out in a country entirely different from that of France and Belgium; those who served there saw, as Major Hull states in his introduction, results which ill prepared them for a campaign fought in weather with a large preponderance of wet days, and upon a soil artificially sown with bacteria, mostly of faecal origin. The nature of the weapons employed also has exercised a potent influence upon the surgical treatment in this war. To surgeons it will be known as "the pointed bullet war," but attention is called to the increased proportion of wounds due to artillery fire and their greater liability to septic infection. Statistical results have had to be excluded at this stage of the campaign in deference to the wishes of the censor.

The chapter on bacteriology of wounds in war has been written by Lieutenant-Colonel Harrison. He urges that in dealing with tetanus "the administration of antitoxin must be supplemented by thorough eradication of the focus of infection." This may be possible where there is a single small wound, but can hardly be carried out where there are several wounds, some of which have involved joints and internal organs, so that it is not possible to say which was the focus. He suggests that 10 to 15 c.cm. of antitoxin should be injected into the lumbar sac and 100 c.cm. intravenously in one or two injections as soon as possible after the commencement of symptoms. For the mechanical removal of bacteria from the depths of the wound Colonel Harrison favours the use of eusol, since it adds to its lymph lavage properties that of being acid, an acid reaction of the medium being inimical to the production of toxin. The use of other strong antiseptics and pastes is condemned, for the aim should be to remove the anaerobes by setting up a free flow of discharge through a sufficient wound opening. This statement is sound common sense.

Dr. Greenfield has contributed a very useful chapter on the general condition of the wounded and their treatment. He emphasizes the importance of giving pituitary extract, condemns the use of strychnine, and recommends full doses of morphine in the treatment of shock; this is in agreement with Crile's teaching. Patients with severe bone injuries stand repeated manipulations of the limb very badly, even when under an anaesthetic. No major operation should, it is said, be attempted without infiltration anaesthesia. Novocain solution $\frac{1}{2}$ per cent. with adrenal chloride had given good results, and if potassium sulphate gr. x be added to each ounce the effect is prolonged and pain after the operation is much lessened.

¹ *Surgery in War*. By A. J. Hull, F.R.C.S., Major R.A.M.C.; with a Preface by Sir Alfred Keogh, K.C.B., M.D. London: J. and A. Churchill, 1916. (Cr. 8vo, pp. 404; 24 plates, 55 figures. 10s. 6d. net.)

Preference seems to be given by other contributors to the use of hypertonic salines rather than antiseptics. The bold statement is made, in speaking of the treatment of septic wounds by excision, that "a septic compound fracture of the skull can be made to heal almost with certainty, provided the patient comes under treatment in reasonable time." This is, we believe, not the experience of all surgeons, and though in a certain number of cases this desirable result may be obtained, the suspicion must remain that it will always be the exception rather than the rule.

An excellent and careful description of the x-ray localization of foreign bodies is given by Lieutenant W. A. Edwards.

Compound fractures must bulk very largely when dealing with casualties in warfare, and it has to be borne in mind that the missile which causes the fracture usually infects the wound, and oftentimes carries into the medullary cavity of the long bones a portion of the patient's clothing. The view taken in the manual is that, with the exception of small perforated wounds, all wounds complicating compound fractures require exploration, which should be carried out as soon as possible after the receipt of the injury. The use of Thomas's splints applied as described by Lieutenant-Colonel Robert Jones is spoken of very highly, not only for the femur but also for the humerus.

The administration of urotropin (15 to 20 grains every three to four hours) is advised in every case of gunshot wound of the head. Attention is called to the opinion expressed by French surgeons "that all wounds of the skull should be trephined at once. Trephining (in their opinion) is the operation of urgency, *par excellence*, in military surgery." A thin flap of fascia from the thigh forms the most convenient tissue for the repair of lacerations of the sinuses.

It is difficult exactly to understand what is meant by the sentence "immobilization by application of a wire may be considered in some cases," which occurs in the discussion of secondary haemorrhage complicating fracture of the femur.

Stress is laid upon the fact that abdominal wounds in this war differ materially from those seen in South Africa, and we gather that Major Hull's view is that where possible practically all cases should be operated upon as soon as possible, early operation being essential, especially when the missile has penetrated the lower and lateral portions of the abdomen. Reference is made to Colonel Mayo Robson's article in the *BRITISH MEDICAL JOURNAL* of December 4th, 1915, and the excellent results to be obtained in such cases.

Captain Miller writes the chapter on gunshot wounds of the chest, and Lieutenant Snowden that on wounds of the peripheral nerves, and Dr. Greenfield has supplied excellent illustrations.

We have attempted to indicate the character of the book by way of quotation rather than criticism, because in this way, perhaps, readers may best be inspired to peruse it for themselves. It must prove helpful to all surgeons who are engaged in the treatment of the wounded at home as well as abroad, and should be in the hands of every officer of the Royal Army Medical Corps.

The French book, entitled general indications for the treatment of wounds in war,² is conceived in a different spirit. It is more dogmatic, and in a sense more elementary. Its author, Professor G. MARION, is surgeon to the great Lariboisière hospital in Paris, and médecin major de première classe—the French army is under the disadvantage that its medical officers are not members of a corps, as in ours. M. Marion has clearly had a great deal of experience in this war; his book is founded on that, and it is all the more interesting because it is very personal. For M. Marion there is always one thing to do and one way of doing it, and the surgeon inexperienced in war wounds who follows his instructions will at least feel that for each there is a well thought out reason. Such a book need not be criticized in detail; it must be taken for what it is—the opinions of a strong personality strongly expressed.

It falls into three parts; the arrangement of the first part is admirably logical. The treatment of a wounded man is divided into three periods—immediate, secondary, and late. It is perhaps due partly to the nature of M. Marion's experience and partly to his manner of presentation that the first two periods are far better dealt with than the last. Of penetrating wounds of the abdomen he says that if an expert surgeon (*chirurgien de carrière*) possessing a complete surgical equipment is called upon to treat a man in whom shock is not pronounced he ought to operate. If the surgeon is not "un chirurgien rompu à la chirurgie abdominale," or if the equipment is in any respect defective, or if the wounded man is profoundly depressed, then the surgeon ought to abstain from operating, satisfying himself with superficial disinfection of the wound, and the application of a simple dressing; an icebag should then be applied to the abdomen, the trunk raised, the diet restricted, 10cg. of opium given daily in two doses, and the patient kept in the ambulance until all danger of peritonitis has passed. The treatment of haemorrhage, of protrusion of intestine, and of lesions of the kidney or bladder, is then more particularly considered. In discussing treatment in the secondary period M. Marion recommends for peritonitis following a penetrating wound median suprapubic incision and the introduction of drains. This treatment, combined with the sitting posture, administration of serum, or such stimulants as camphor or caffeine, will, he says, now and then save some of these cases. Nothing more, however, should, he thinks, be done, for an attempt to suture the intestinal wound at this stage will cause diffusion of the infection, even if the patient survives the operation.

Of fractures of the cranium he says that even if there be no more than a simple fissure there can be no doubt that it is urgently necessary to trephine provided the environment is suitable. "It has been fully proved," he adds, "that as a cranial operation is benign and efficacious if performed before any evidence of meningo-encephalitis appears, so any operation performed after the lighting up of this dreaded complication is useless." M. Marion adds to many of his sections "don'ts"; those to this section are: (1) "Don't be satisfied with disinfecting the wound without touching the fracture"; (2) "Don't, when trephining is performed, make explorations in the brain with forceps, probes, etc." In the next section, dealing with penetrating wounds, it is said that the indications are the same, and the "don't" here is "Don't search for the projectile in the course of a trephining performed to secure disinfection of the wound." The extraction of the foreign body, he says, should only be attempted after all trace of infection has disappeared, and after it has been accurately localized.

The second part of the book is concerned with the localization of foreign bodies, and an apparatus in which the method of crossed cords is used is described at length, and strongly recommended.

The third part of the book describes apparatus for the treatment of complicated fractures and joint wounds. Like many other French authorities, M. Marion makes much use of plaster, but he praises and illustrates several splints made with the aluminium rods issued by the British Army Medical Service. We note with satisfaction that M. Marion points out the necessity, in treating injuries of the wrist, of keeping the joint in extension, inasmuch as if ankylosis does occur the position of extension is that in which the fingers will have the greatest power.

NOTES ON BOOKS.

MEDICAL men all the world over owe a debt of gratitude that is always increasing to those responsible for the compilation of the *Index-Catalogue of the Library of the Surgeon-General's Office, United States Army*.³ As any one who has ever had to look up references in medical literature knows, the *Index-Catalogue* gives the best lists of the literature of medical authors and medical subjects in existence. The library on which it is based contains over 190,000 bound volumes and 328,000 pamphlets. The first and second series contain over two million titles of authors and subjects. The last volume to appear is the twentieth of the second series, including from V to Waterworks.

² *Indications générales du traitement des plaies de guerre*. Par G. Marion, Médecin Major de 1^{re} classe. Paris: A. Maloine et Fils, 1916. (Post 8vo, pp. 190; 38 figures. Fr. 4.50.)

³ *Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Second series, vol. xx. V-Waterworks*. Washington: The Government Printing Office, (Imp. 8vo, pp. 603.)

SATURDAY, APRIL 8TH, 1916.

WHAT IS A TEUTON?

Not long ago we lived in happier times; we had a settled nomenclature in our English anatomical textbooks until one coined in Germany was foisted on us; we had well-recognized Latin names for the various species of animals until a new law was introduced—largely German—that has landed zoologists in a Tower of Babel, no man being certain of what the proper name for a species may be. In olden times the Aryans were a real live folk; they lived, originally in the high plateau region somewhere between the Himalayas and the Caspian; they broke westwards into Europe, bringing with them the mother forms of all the tongues we now speak, and they broke eastwards into India. Now the Aryan in the form we got to know him and like him is going; he is proving a "Mrs. Harris"—a supposititious person called into being by students of words who wanted to account for the relationship which exists between European and some Eastern languages. In those happier times we knew who the Kelt was—we wrote the word as "Celt" then; for us in these islands he was the descendant of an ancient native of the "Celtic fringe"—Ireland, West Scotland, Wales, and Cornwall. Much as the various constituent peoples of our Celtic fringe differ in stature, in colouring, and in make of body, there is one character they have in common—in all of them there prevails the same type of head form. It is not enough to say that they are long-headed (*dolichocephalic*), for there are many types of long heads, just as there are many types of round heads.

No greater mistake could be made—and modern anthropologists have not taken care to emphasize this aspect of the matter—than to suppose that two skulls which have the same proportion of width to length—that is, have the same cephalic index—are of identically the same type and race. In the case of our Celtic fringe the long-headedness is of the same type; the British Kelt is, in the vast majority of cases, a long-headed individual. In France, ever since the time of Broca, a totally different kind of individual has been regarded as the true Kelt. Broca accepted Caesar as the standard authority; to Caesar the inhabitants of middle Gaul were typical Kelts; graves of the Roman period show that Caesar's Gauls had the same rounded—or brachycephalic—head form as the modern French. For Broca—and Broca was followed by anthropologists in nearly all countries—the Kelt was a broad-headed individual, with his own peculiar form of broadness.

We do not know when the long-headed and broad-headed European strains separated from a common stock, but we do know that head form breeds true over a space of ten thousand years, and that the difference in head form is one of real racial significance. We therefore cannot continue to use "Kelt" as a racial name, for we do not know whether the speaker is referring to one or other of two opposite European stocks—the broad-headed central European or the long-headed West Highlander.

In those olden times, before King Edward came to the throne, we were happy and almost unanimous in

our use of the word "Teuton." The Anglo-Saxons were Teutons; the Germans said we were their cousins; standard works on geography and ethnography, both in England and in Germany, still reproduce a map wherein Germany, Sweden, Norway, Denmark, Holland, and Great Britain are coloured in the same tint, showing them to be parts of Teutondom and their inhabitants Teutons.

Is a Teuton, then, an Englishman or a Prussian? We are at deadly war with Germany, but that does not mean we may not be cousins; near relatives have often the fiercest of quarrels. We had a bitter feud with our children in America. May we not be making the same mistake about the Teuton as about the Kelt? A close study of a book which has just appeared¹ from the pen of the Right Hon. J. M. Robertson, M.P., leads to the conclusion that the word "Teuton" is applied to two kinds of men which, in an anthropological sense, are totally different, and that, like "Kelt," "Teuton" also must be discarded from our scientific vocabulary. Mr. Robertson has won for himself a high reputation in many lines of human endeavour as journalist, politician, historian, and philosopher, but with all his learning there is one department of quite useful knowledge he has not really absorbed, and that is the study of human races as practised by modern anthropologists. He examines what some of them have to say regarding the German shape of head, and finds they can give him no help. He takes the writings of Houston Stewart Chamberlain almost as seriously as the Germans have done—the writings which picture the natives of the German empire as blessed with all the qualities of heroes, as the supermen of the present, and masters of the world in the future. British anthropologists have never made that mistake, but they have made an equally great one—they have never taken the trouble to inform their countrymen that the word "Teuton" covers two very different types of humanity.

That discovery was made by a man who is held in high repute by every one who values the history of medicine—Virchow the pathologist. The discovery, which came to him in the light of a tragedy, was made in the following manner: At the close of the Franco-German war Quatrefages, who then occupied the chair of anthropology in the Natural History Museum, Paris, made certain aspersions regarding the racial nature of the Prussians. Virchow took the charge quite philosophically: he admitted that very little was known of the racial nature of the German people, but it is also quite apparent from the manner in which he set to work that he was confident of proving that his fellow countrymen of the north were true Germans or Teutons of the classic type—long-headed, fair-skinned, fair-haired, and blue-eyed. He went to find and study his typical German on the west coast—Holland and Frisian lands north of Holland. He found the classic German there—a man not unlike the typical Norwegian, Swede, Dane, or Englishman. He then set on foot an excellent scheme—one which aimed at taking a census of the physical characteristics of the German people—beginning with school children. The colour of the hair and eyes was taken first; in that respect Prussia came off with flying colours; its natives had the fairest hair and bluest eyes of all the people within the empire. In that respect the attempt to prove that the German people were classical Teutons was successful. But as regards head form the case proved quite different; Virchow soon became convinced that the vast majority of the German

¹ *The Germans: (I) The Teutonic Gospel of Race; (II) The Old Germany and the New.* By the Right Hon. J. M. Robertson, M.P. London: Williams and Norgate. (Price 7s. 6d. net.)

people were not long-headed. In the south—Bavaria, Württemberg, and Baden—the people were, almost without exception, broad-headed of the Alpine or French Keltic type, and with dark hair. In the north and north-east—Prussia, Brandenburg, Posen, and Silesia—the people were broad-headed of the Slavonic type, but with fair hair. Of the seventy millions of people now living within the German empire, not more than eight millions, occupying a coastal fringe on the west and scattered along the Baltic shores, are of the classical fair-haired long-headed type. Which is the Teuton—the small western long-headed fringe or the round-head central mass? In a strict anthropological sense the word "Teuton" has ceased to be usable.

It cannot be too clearly understood that Germany and Britain stand not only for two opposite ideals of life but also for two opposite ideals of manhood. In Europe to-day there are about 420 millions of people. In an anthropological sense they fall into four groups. The long heads are in the West and in a minority. They have now, they have had since the dawn of history, the command of the sea. Spain and Portugal stand for the dark-haired long heads; Great Britain, with a dash of the dark long heads in her "Celtic fringe," stands for the fair-haired long heads. She has behind her the Scandinavians, the Danes, the submerged German West, the Dutch, the Flemings, and to some degree the people of Normandy—about ninety millions of fair-skinned long heads all told.

It did not need the present war to prove that war has little to do with race; it has much more to do with language, tradition, and national ideals. This at least is certain, that so far as Britain is concerned in the present war, it is not an inter-Teutonic strife; nothing is more certain than that the great mass of the Germans and of the British people are of a totally distinct lineage.

INDUSTRIAL FATIGUE AND ITS CAUSES.

THE Health of Munition Workers Committee has added to its list of valuable memorandums one dealing with the causes of industrial fatigue,¹ which seems to set the crown to its work, for it is written with physiological knowledge and human insight. A new era will open in the prosperity and happiness of the nation if employers and workpeople can be made to grasp the importance of such an essay as this, and recognize that the physiological laws of life must be studied and followed. A short-sighted struggle for more money, shorter hours of work, and trade union restrictions of output cannot secure human happiness. It is not these crude conditions of the daily task that matter, but the opportunities of developing mind and character, of perfecting skill, of gaining success and advancement by triumphing over obstacles, of keeping physically fit in hygienic surroundings, of securing leisure to enjoy the money earned, opportunities to spend it wisely in a garden city surrounded with playing fields, and affording every worker a chance of realizing the beauty and grandeur of the universe, of the changing seasons, the flowers and the stars.

The Committee defines fatigue as the sum of the results of activity which show themselves in a diminished capacity for doing work, and points out that it is wholly fallacious to take the bodily sensations as a guide and measure of fatigue, for there may be diminished capacity for work before any signs of

fatigue appear in sensation. Fatigue results not only from the exhaustion of substances supplying chemical energy for doing work, but from the accumulation of the products of the chemical changes. It can be compared, not to the running down of a clock, but to a clogging of the wheels with dirt. The chemical products of activity are removed by the blood, and time is required both for this and for the process of restoration. "If the activity is repeated too quickly to give time enough for restoration after each action, fatigue will become progressively more intense as the debit balance accumulates."

Since the muscles are protected from exhaustion by the nerve cells failing first, the problems of industrial fatigue are almost wholly problems of fatigue in the nervous system. In the tired man fatigue is felt in the muscles, it is referred to them, but the fatigue is really that of the nervous system. "It is well known that a man apparently run to a standstill in a race may, upon some new excitement, run freshly again, under augmented stimulus from the central nervous system, initiated there perhaps in part along new paths." For every action a given rhythm of activity allows exact recovery after each act, and the heart, for example, beats incessantly for the life of a man without any accumulated fatigue. Complicated co-ordinations in the nervous system may by training become capable of maximum efficiency at a more rapid rhythm than was possible in the untrained state. "It is the problem of scientific management to discover in the interests of output and health of the workers what are the maximal efficiency rhythms of the various faculties of the human machine." This must be done for short spells, hours of shift, periods of sleep and holidays. Scientific management is illustrated by the following anecdote: Two officers at the front, for a friendly wager, competed in making equal lengths of trench, each with an equal squad of men. One let his men work as they pleased, but as hard as possible; the other divided his men into three sets, to work in rotation, each set digging their hardest for five minutes and then resting for ten, till their spell of labour came again. The latter team won easily.

The true sign of fatigue is diminished capacity; measurement of output, therefore, will give the most direct test. Since overstrain may not only reduce the capacity at the moment, but for long periods, it is plainly uneconomical to allow overstrain, and scientific management will see that the right kind of work is apportioned to the right individual. "Astonishing results, bringing advantages both to employers and employed, have been gained in other countries by the careful selection of individuals for particular tasks based not upon the impressions of foremen but upon the results of experiment." Unfortunately there is against the development of such scientific management the suspicion that any device for increasing output will be used for the profit of the employer rather than for the increased health and comfort of the workers.

"An important and early sign of fatigue in the nervous centres is a want of co-ordination and failure in the power of concentration." This may be shown objectively in an increased frequency of trifling accidents. The accumulated results of fatigue damage the general health and will be reflected in sickness returns, in returns of lost time, and in a sense of staleness among the workers—a feeling of being "done up" or "fair whacked." This feeling may result not only in lethargy and indifference, but in a craving for change and excitement, and may lead to indulgence in alcohol.

¹ Health of Munition Workers Committee. Memorandum (No. 7) on Industrial Fatigue and its Causes [Cd. 8213]. To be obtained through any bookseller. Price 1d.

A works manager worked hard 361 days out of 365, and looked worn. A skilled tool maker had had eight days' holiday, including one for a funeral, since the war began (fourteen months); he complained of the strain on his nerves. The official of a very large trade union said that overtime was excessive and the skilled workmen were becoming "nervy." These are representative examples of the reports gathered from the evidence collected by the Committee. Proper attention to the need for weekly rest would have prevented the reduction of output by such fatigue and staleness. The Minister for Munitions has accepted the Committee's recommendation concerning Sunday labour, and formulated the need for the Sunday rest throughout the controlled factories. It is remarkable that so far the Government arsenals, Woolwich and Enfield, do not seem to have carried out the instructions, and continue to work thirteen shifts in fourteen days. "Misguided efforts to stimulate workers to feverish activity in the supposed interests of the country are likely to be as damaging to the desired results as the cheers of partisans would be if they encouraged a long distance runner to a futile sprint early in his race."

Examples are given of the value of intelligent management. "At a large shell-making factory the men for the early months of war worked seven 12-hour day and seven 12 hour night shifts in the week. More recently Sunday work has been stopped (or at least every man has a weekly day of rest), and the men work from 6 a.m. to 7.30 p.m. with an hour and a half off for meals. These hours are long, but as a result of improvement in organization they now produce an increased number of shells from half the number of workers." At another large factory the men engaged in the heavy work of moulding were required by the management to rest fifteen minutes in every hour of work. The output was found actually to be increased. At another factory fifteen minutes' recreation for the girls in the open air at 11 a.m. increased the output. Educational authorities recognize that no class should last more than three-quarters of an hour, and that then the students should have a run round the playground. Nevertheless, factory girls are put to sit at a bench for stretches of four or five hours.

"Elevens" and "fours," an excellent custom among agricultural labourers, should be made compulsory in all factories. The objection is that it takes so long to empty the shops. But the shops should not be built to cover acres, but long and narrow so as to ensure good ventilation through a large surface of wall, then there would be no delay in emptying them into playgrounds which should be provided in every factory.

PENETRATING WOUNDS OF THE ABDOMEN.

In the detailed report to the Medical Research Committee presented by Captain Fraser, R.A.M.C., and Captain Bates, R.A.M.C.(T), and printed upon an earlier page of this issue, will be found an account of the results of operation, or the abstention from operation, in a number of cases of penetrating wounds of the abdomen. It is needless to say that thousands of such cases have occurred during the course of the present war, and that they are of the greatest interest to the operating surgeon because their unfortunately high mortality may admit of material reduction. It is not to be doubted that such a reduction will follow the discovery and application of the methods of surgical treatment best designed to meet the require-

ments of each individual case, and the report gives abundant evidence of the importance of this principle. A second principle upon which stress must be laid is the importance of making a thorough examination of all the abdominal viscera before the operative procedure is decided upon in cases in which the possibility that several visceral injuries will have to be repaired cannot be excluded. For example, where the small intestine has been injured, the authors of the report emphasize the necessity for scrutinizing every portion of the small intestine and of the large in succession before any decision as to treatment is reached; details of the temporary and final methods of dealing with such injuries are given, and the progressive character of the bleeding that follows laceration of even the smaller mesenteric vessels is noted. It will be seen that the authors express a general preference for the performance of a lateral intestinal anastomosis in cases of multiple injuries of the small gut, for the reason that they find that resection of the injured tube is so frequently followed by distension and paralytic ileus in the proximal segment. It would be interesting to learn how the results of the method of dealing with these cases advocated a few months ago in this JOURNAL¹ by Captain (temporary) O. W. Richards, R.A.M.C., would compare with those obtained by the authors of this report. It will be remembered that Captain Richards advised the resection of "not only the injured portion, but also as much bowel above it as is likely to remain out of action and constitute a functional obstruction," a point to which Barker had previously called attention in relation to strangulated hernia.

According to Colonel Cuthbert Wallace, men shot through the abdomen die mainly from one of three causes—haemorrhage, peritonitis, or intestinal obstruction following peritonitis. Captains Fraser and Bates conclude that immediate laparotomy, particularly if haemorrhage is suspected, or laparotomy after the lapse of an hour or two, is indicated in the vast majority of cases of penetrating wounds of the abdomen. To combat the shock from which he is suffering the patient is stimulated by warmth and by the exhibition of pituitary extract before the operation. Every precaution is taken to minimize shock during the operation, and several pints of saline are given subcutaneously while it is in progress. The danger of post-operative intestinal obstruction is met in the manner already indicated. The third danger to which the patient is particularly exposed, that of peritonitis, is minimized by washing out the abdominal cavity in early cases with extensive soiling of the peritoneum, and in later cases, with or without evidence of peritonitis, by drainage through a single Keith's tube passed into the pouch of Douglas. For the rest, the post-operative treatment is carried out on the usual lines, special attention being paid to the administration of fluids by the rectum or by subcutaneous infusion.

What of the results of treatment on these lines? The authors of the report say that the surgeon "must be prepared for repeated most bitter disappointments, but when one comes to view a series of cases, the gains seem infinitely greater than the losses." A new method of dealing with the peritonitis and paralytic intestinal obstruction that prove fatal to many of these patients is developed in a paper by Captain Sampson Handley, R.A.M.C.(T.), which will also be found in this issue. He argues that in all probability many patients shot through the abdomen and suffering from the

¹ BRITISH MEDICAL JOURNAL, 1915, II, 213.

consequent peritonitis die from the onset of intestinal obstruction rather than from the direct results of the peritoneal infection. He has found that such general peritonitis is rarely universal, and that it usually begins deep down in the pelvis and spreads upwards through the peritoneal cavity. He contends that so long as a patient with general peritonitis remains capable of active vomiting it must be assumed that the upper part of his small intestine, the stomach, and probably the transverse colon, are not paralysed, not yet having been reached by the peritoneal infection as it spreads upwards among the abdominal viscera. Hence he concludes that the patient's life may be saved, in spite of the extensive paralytic obstruction of the lower parts of the intestinal tube, by immediate operative interference. If the peritonitis remains confined to the pelvis, ileocolostomy to the ascending colon with caecostomy are, he thinks, indicated; but in cases of so-called general peritonitis extending roughly up to the level of the umbilicus, jejunocolostomy to the transverse colon and caecostomy. In all cases pelvic drainage must be provided. These operations provide an emergency alimentary canal consisting of stomach, jejunum, transverse and ascending colon, and caecum; and this canal will provide the patient with clean food and fluid that may tide him over the critical period of his illness and stop the spread of the general peritonitis that would have proved rapidly fatal had no such assistance to his resisting powers been provided. There is a thoroughness about Captain Handley's hypotheses and conclusions that renders them attractive and makes it desirable that they should be put to the test of further actual experience, as he himself suggests.

OFFICIAL RECOGNITION OF THE ENROLMENT SCHEME.

THE official statement of the War Office with regard to the enrolment of medical men for the military services, which has been widely published in the press and the full text of which will be found in the SUPPLEMENT for this week, affords a further and final recognition of the work of enrolment carried out by the three representative bodies of the medical profession—the Central Medical War Committee for England and Wales, the Scottish Medical Service Emergency Committee, and the Irish Medical War Committee. As the official statement points out, the real purpose of the enrolment scheme is to secure that those doctors are selected for military purposes who can best be spared at the particular date, and from the particular place, with due regard to the civil needs of the population, to the personal circumstances of the doctor, and to the requirements of His Majesty's Forces. The War Office has officially recognized, and now relies upon, the Central Medical War Committee and the corresponding committees in Scotland and Ireland. The official statement correctly uses the phrase "military services," for obviously the Royal Navy has an equal, if not a paramount, claim, but this has been so thoroughly recognized that up to the present the navy has, we believe, found no difficulty whatever in obtaining the medical officers needed. The appeal of the Medical War Committees has consequently been for the army, but any medical man who prefers to offer his services to the navy will not find any difficulty in so doing. The decision of the Central Medical War Committee, reported in the SUPPLEMENT, with regard to the proportion upon which the calling up should proceed will relieve the anxieties of those medical men who may have feared that calls might be made from too limited a roll.

Experience shows that the calls are likely to be small in respect of the number of men required at any one time, and will only recur at intervals as the need arises. The demand on the medical profession will be gradual and can be easily met, but can only be quite efficiently met if all medical men of military age who have not yet enrolled will do so with one of the three committees. The trust now reposed in these committees by the military authorities will impel every patriotic member of the profession to enrol. By so acting he will do his share towards rendering it possible for the medical profession to meet both civilian and military needs without recourse to methods of compulsion.

WITH THE RUSSIAN RED CROSS.

In the Norwegian daily paper *Tidens Tegn* for March 16th an enthusiastic account is given by Dr. C. Johannessen of the Red Cross in Russia, whence he has recently returned after a visit of four months. He spent three months at the front attached to Princess Kcenia Aleksandrowna's hospital and train service. He seems to have been exceptionally fortunate in securing this appointment, as apparently no other neutral surgeon was permitted to share in the medical and surgical work at the front. He entered Russia through Finland, travelling with a draft of wounded Russian soldiers released from Germany. In Petrograd he worked for a short time under Professor Oppel, who, when he had convinced himself of Dr. Johannessen's surgical attainments, helped him to reach the front. Here the staff of five English-speaking Russian nurses bridged the linguistic gap between Dr. Johannessen and his Russian patients. He was much impressed by the physique and equipment of the Russian soldiers; so well were they clothed that, among the 3,500 soldiers under his care, there was not a single case of frost-bite. The food was abundant and good, and even at the front the soldiers were able to take a bath once a week. The medical arrangements were also in other respects so satisfactory that there was no serious epidemic of any kind. He was greatly struck by the cordial, almost fraternal, relations between officers and men, and by the adaptability of the peasant soldier. When the first waves of German poison gas were approaching the Russian trenches, one of the soldiers called on his comrades to light fires in front of their trenches so that the oncoming gas would be carried upwards by the draught instead of descending into the trenches. As an example of the self-sacrificing efforts made by the various towns, Dr. Johannessen describes how, in the course of one month, hospitals with a total accommodation for 64,000 wounded were provided by Moscow alone. Since then this number has been more than doubled, and the town has provided forty ambulance trains in addition to other conveyances for the wounded. One of the most striking features in Russia was the calm and deliberate spirit in which everything was done. There was no disorderliness, no rowdiness, no drunkenness; the very sobriety of the nation was perhaps the truest sign of the unflinching spirit in which Russia was preparing to redeem the mistakes of the past.

PHYSIOLOGICAL TESTS FOR AVIATORS.

IN the BRITISH MEDICAL JOURNAL of March 11th a brief account of certain injuries and diseases of aviation was given, based on observations made by Staff Surgeon H. V. Wells, R.N., and Dr. G. Ferry. A study of the physiological methods that may be employed with advantage in the testing of would-be aviators has just been published in a Paris medical journal,¹ by Professor Camus and Dr. Nepper. They point out that, quite apart from the general physique and organic health of the candidates for aviation, attention should be paid to the promptitude and quality of the responses given by their nervous systems to the various stimuli they will receive in the course of

¹ *Paris médical*, 1916, vi, 290.

their work. It is essential, on the one hand, that they should respond without delay, so that tactile, auditory, and visual impressions may be expected quickly to lead to movements of adaptation or defence. On the other hand, it is equally important that the aviator should not be unduly at the mercy of his emotions, such as fear, excitement, nervousness, and the like. As every physiologist knows, reaction times and responses to different stimuli are quantities readily capable of exact measurement; the necessary apparatus is, indeed, the stock-in-trade of psychological and psycho-physiological laboratories. Professor Camus and Dr. Nepper have accordingly used the well-known electric chronometer of d'Arsonval for determining the candidates' reaction times or latent periods on the receipt of visual, auditory, and tactile stimuli, the mean of ten separate determinations being taken as the figure in each case. A good candidate will have a latent period of about 0.19 second for visual stimuli and 0.14 to 0.15 second for tactile and auditory stimuli. The figures will be considerably larger in the case of unsuitable candidates—for example, 0.3, 0.27, and 0.27 second in one instance, 0.28, 0.2, and 0.22 second in another, to quote actual cases. The method of investigating the stability of a candidate's nervous system is different. Apparatus is rigged up to record on the familiar smoked drum the cardiac rhythm, the respiratory rhythm, and, by means of a finger placed in a plethysmograph, any modifications that may take place in the peripheral vasomotor system; in addition, a record of any muscular tremor that may be present is made. While all these records are in progress, revolvers are fired, magnesium powder is flashed off, or cold cloths are dashed on to some exposed part of the candidate's skin. With a good candidate these violent external stimuli will produce little change in the tracings; a bad candidate will show cardiac, respiratory, or vasomotor irregularities due to excess of emotion at such alarms and excursions as these. It is clear that the man who is a bit slow in the uptake will come out badly in the first series of tests, while the tests of the second series should serve to detect and unmask the unduly nervous and excitable candidate. These novel methods of examining would-be aviators are still on their trial and have not yet reached finality in form, but the results they have yielded are said to be promising. It is undeniable that they appear to give numerical measurements of qualities that must be of importance to aviators, in place of the mere impressions as to the suitability or unsuitability of candidates that must at present influence the opinions of those who are responsible for the selection of likely fliers.

MANY NAMES FOR THE SAME THING.

We doubt whether any members of the medical profession could be found who would dissent from the statement that the practice of bestowing a series of different names on a single substance of known chemical composition is from their point of view an unqualified nuisance, whatever advantages it may have from the point of view of manufacturing enterprise. Some, however, may be unaware of the extent and frequency of this practice, though instances will occur to every one, and a good many were given in the series of articles on the chemical constitution of certain proprietary drugs published in the *JOURNAL* at the end of 1914 and the beginning of 1915. One such instance was that of acetyl-salicylic acid, which is in the *British Pharmacopoeia*, 1914, under that name. It was introduced under the trade name aspirin by a German firm; other firms have applied the names acetysal, acetosalin, aletodin, saletin, salaretin, xaxa, and empirin to the same substance. Another example is the drug introduced under the trade name atoxyl, also by a German firm; it is sodium para-aminophenyl-arsenate, but in the *British Pharmaceutical Codex* it is given the shortened name, sodium aminarsonate. Trade

names for this body are arsamin and soamin, but with regard to the latter it should be said that it is stated to contain five instead of four molecules of water of crystallization. Again, the drug which appears in the *British Pharmacopoeia*, 1914, under the name hexamine, a contraction of its chemical name, hexamethylenetetramine, was introduced under the trade name urotropine, and other firms applied to the same substance such names as aminoform, ammonio-formaldehyde, ammonaldehyde, cystamin, cystogen, formin, metramine, urisol, aritone, xametrin, and vesalvine. Other instances might easily be added from past history, and we fear that there is a risk of such a confusion arising in respect of the substance para-toluene-sodium-sulphochloramide, suggested as a wound antiseptic by Dr. Dakin and Professor Cohen; its clinical use has already met with considerable success, to which our columns have on more than one occasion borne witness. The theoretical basis of the work, full details of the preparation of the substance, and the early practical results of its use were published by the originators in the *BRITISH MEDICAL JOURNAL* of January 29th, 1916, p. 160. It was very desirable that the substance should be produced in commercial quantities, and we were therefore glad to learn that its manufacture had been undertaken by Messrs. Burroughs, Wellcome, and Co. In submitting samples of their preparation they informed us that the name chloramine, or chloramine-T, suggested by the scientific workers responsible for its introduction, had been found to clash with that of an American proprietary preparation, and that they proposed to apply the new name, tolamine, to the para-toluene-sodium-sulphochloramide made by them. In a notice of these samples published in the *JOURNAL* of February 19th, p. 289, we endeavoured, both in the title and in the text, to make it plain that tolamine was a new name used by Messrs. Burroughs, Wellcome, and Co. for the substance which Dr. Dakin and Professor Cohen had proposed to call chloramine-T. We acquiesced in the proposed use of this name in the hope that confusion might thereby be avoided, but this hope does not seem likely to be fulfilled. As Dr. Dakin and Professor Cohen, who carried out their researches for the Medical Research Committee, published full particulars of the mode of preparation of para-toluene-sodium-sulphochloramide it was open to any competent firm of manufacturing chemists to make the substance. We ought, perhaps, to have foreseen that this would happen. As a matter of fact, we shortly afterwards had occasion to mention (March 25th, p. 454) that another firm, Boots Pure Drug Company, had manufactured the substance, and were selling it under the name suggested by the originators, chloramine-T. We are told that other firms are manufacturing the substance, or propose to do so, and that the name chloramine-T suggested by its originators, which is free for all to use, appears likely to be generally adopted. Messrs. Burroughs, Wellcome, and Co., we are informed, have registered tolamine as a trade name, and the medical profession will understand that if they order para-toluene-sodium-sulphochloramide under the name tolamine, the proprietary preparation of this firm must be supplied. We quite admit that for many synthetic substances in common use it is essential to find some short convenient name when, as often happens, the scientific name which expresses its constitution is inconveniently long; obviously, para-toluene-sodium-sulphochloramide is a case in point, but Dr. Dakin and Professor Cohen furnished a short name for it, and, we understand, do not approve of the word "tolamine." While we think that the wishes of the discoverers ought to be respected, we only desire here to make our own position clear, which is that the system of various firms giving different proprietary names to the same substance is not only inconvenient to the medical profession by causing confusion, but is, in our judgement, undesirable on general scientific grounds.

AN ESTIMATE OF THE NUMBER OF DEATHS
CAUSED BY ALCOHOL.

In the *Alliance Year Book for 1916* Dr. Norman Porritt publishes an estimate of the number of deaths in England and Wales during the year 1913 directly or indirectly caused by the abuse of alcohol. Dr. Porritt has proceeded on the following lines: In the first place he sets out a number of causes of death to which the abuse of alcoholic beverages may be assumed, with more or less probability, to have directly contributed. This list includes, among others, cirrhosis of the liver, diseases of the heart, cancer, tuberculosis, and epilepsy. The total deaths registered under each heading are multiplied by a factor varying from one-eleventh to unity and the products summed. The total is given as the direct alcoholic mortality. Under indirect mortality Dr. Porritt ranks a certain proportion of the deaths attributable to the consequences of venereal disease and more than one-sixth of the deaths under 5 years of age. In this way Dr. Porritt arrives at a grand total of 77,416 deaths. That in some of the diseases named by Dr. Porritt the abuse of alcohol is of direct etiological significance, and that in almost all it unfavourably affects the prognosis, are propositions no medical man is in the least likely to dispute. On the other hand, hardly any one will be prepared to regard Dr. Porritt's estimates of the proportions really attributable to alcoholism as much more than guesses. Thus he writes: "In 1913, in England and Wales, 1,700 persons between the ages of 25 and 65 died from diarrhoea and enteritis. In at least a sixth of these the fatal result would be due to alcohol." These and similar assertions may be true or false, but are evidently not within the pale of scientific discussion. Dr. Porritt thinks that if death certificates were confidential documents an adequate record of the causes of death would be obtained. There is force in his contention, but in the particular case under notice it is perhaps doubtful whether much would be gained unless a uniform system were introduced. The more attribution of the death to the effects of alcoholism would, we think, be of little value owing to the wide individual divergences of opinion which must occur as to the relative importance of alcohol as a predisposing or determining cause in different diseases. If, however, it were possible to make a statement as to the habits of the deceased with regard to the use of alcohol in all cases, then an analysis of the returns might yield important information. As, however, the knowledge of the certifying practitioner with respect to the habits of his patient must often be imperfect, even these returns would be subject to considerable errors. In any case such an alteration in our system of certification raises many delicate questions which cannot be discussed now.

Medical Notes in Parliament.

The Budget.—So far as can be judged from the Chancellor of the Exchequer's budget statement on April 4th, the increases in taxation will not specially affect members of the medical profession in the pursuit of their calling except in respect of the increased license duty on motor cars and motor cycles, which in many districts have now become indispensable to medical practitioners. The rates for cars not exceeding 16 h.p. will be doubled, and above that trebled. On motor cycles the duty will be £2 2s. if under 4 h.p., and above that three-fourths of the duty chargeable on motor cars of like horse power. Medical men will, we presume, continue to pay half the duty in respect of a car kept for professional purposes. With regard to income tax, the rate on earned income is to be 2s. 3d. in the £ up to £500 a year instead of 2s. 1½d.; from £500 to £1,000 a year 2s. 6d. instead of 2s. 1½d. Thereafter the scale rises by stages to 5s. in the £ on earned incomes when the total income exceeds £2,500.

¹ *The Alliance Year Book and Temperance Reformer's Handbook for 1916*. Manchester: United Kingdom Alliance, 1916. (Price 1s.)

On unearned income the new scale will begin at 3s. on incomes not exceeding £300, and will rise by stages of 6d. to 5s., which will be paid on incomes exceeding £2,000. On this, as on many other points, it will be necessary to await the full statement which will be contained in the white paper and the bill, and we propose to recur to the matter shortly. Meanwhile, it may be noted that the grievance with regard to income tax on military pay is so far met that Mr. McKenna stated specifically that income received as pay for service in the naval and military forces will not be subject to the additional rates of tax. The points which came in for most criticism in the short debate following Mr. McKenna's statement were the proposed taxes on railway tickets, on matches, and on mineral waters.

Notification Fees.—The Local Government (Emergency Provisions) Bill, introduced into the House of Commons by the President of the Local Government Board, carries out in Clause 5 the recommendation of the Retrenchment Committee (see *JOURNAL*, March 4th, p. 347 and p. 350) to the effect that the fee for the notification of infectious disease occurring in a practitioner's private practice should be reduced from 2s. 6d. to 1s., the fee hitherto paid for notifications of cases occurring in his practice as medical officer of any public body or institution. The same clause requires notification of any case of infectious disease occurring in any building, tent, van, shed, or similar structure in the occupation of His Majesty's Forces, or of any person employed by the Admiralty, the Army Council, or the Minister of Munitions, if it would have been the duty of the medical attendant to notify it if it had occurred elsewhere. The local authority is to pay the fee of 1s. to the medical attendant whether the case occurs in his private practice or otherwise, unless he be a medical officer or a practitioner who holds a commission in any of His Majesty's Forces, or is employed by the Admiralty or the Army Council, and is prohibited from engaging in private practice.

War.

Mesopotamia.—In reply to Mr. Malcolm, on March 30th, the Secretary of State for India said that the inquiry which was being conducted by Sir W. Vincent and General Bingley was confined to the medical and hospital arrangements of the Mesopotamian campaign. Mr. Chamberlain added that he assumed that it would embrace all matters relative to the sufficiency or otherwise of the provision made in India and Mesopotamia for medical personnel, stores, and appliances, and as to the organization of medical relief and the arrangements for dealing with the sick and wounded in the field, at the base, and in transit to the base. He had issued instructions that the Commission should fearlessly ascertain and assign the responsibility for the breakdown of relief, whether individuals or the system were to blame. The Viceroy had invited Mr. E. A. Ridsdale, Red Cross Commissioner, now en route from this country to Mesopotamia, to join the Commission as a member.

Antityphoid Inoculation.—The anxiety of some members with regard to the scruples of conscientious objectors extends to those who object to antityphoid inoculation. Mr. Anderson asked, on March 28th, whether recruits who objected to antityphoid inoculation would be allowed leave in the ordinary way, provided they produced evidence from the M.O.H. of the district they intended to visit stating that the neighbourhood was free from typhoid fever. Mr. Tennant replied that the necessity of preventing the introduction of enteric fever into military camps was paramount, and necessitated that leave should be granted sparingly to men who objected to inoculation. He did not think that the suggestion with regard to the M.O.H. provided sufficient safeguard that uninoculated men on leave would not bring back infection.

Royal Army Medical Corps.—Mr. Shirley Benn asked if young physicians and surgeons, recognized as modern practitioners who join the Royal Army Medical Corps, are made junior officers and have to take their orders from men who, whether clever or stupid, have received their promotions through length of service. Mr. Tennant: If my hon. friend could provide an

infallible criterion for distinguishing between clever and stupid people, and if he could secure its universal and willing acceptance by all the varied and numerous parties concerned, some beginning might be made to put in practice the Utopian system of his choice. In the meantime, the answer to his question is that in the army, as in most professions, the juniors take their orders from the seniors. Mr. S. Benn: Am I to understand that medical qualifications are not taken into consideration? Mr. Tennant: It depends, of course, on the officer's rank.

Tuberculous Soldiers and Sailors.—In reply to Mr. R. McNeill, on April 4th, the Financial Secretary to the War Office said that soldiers who became medically unfit for further service owing to tuberculosis were not sent to their homes when discharged from the army. Arrangements existed with the Insurance Commission by which those men who were insured under the Insurance Act were, if they desired, sent to sanatoriums. Similar arrangements existed with the Local Government Board for men who were not insured, sanatorium treatment being provided as a special privilege. Mr. Forster declined to accept the suggestion that soldiers and sailors suffering from tuberculous disease should be kept undischarged for a period of not less than six months in hospitals specially reserved for them.

Insurance Premiums.—The Financial Secretary to the War Office stated, on April 4th, that shortly after the outbreak of war negotiations were opened with insurance companies with reference to life policy holders on military service in France. The result was that in the case of officers insured before the war extra premium was generally foregone or charged at a low rate, but this arrangement did not apply to fresh insurances.

Army Pensions.—In reply to Mr. Godfrey Collins, the Financial Secretary to the War Office stated, on March 29th, that it was roughly estimated that the cost of pensions arising out of the present war for the year 1915-16 would amount to £2,600,000, and for the year 1916-17, assuming the war to last throughout the year, to £10,000,000. There was, in addition, a charge of nearly £5,000,000 for pre-war pensions.

Wounded Soldiers Discharged.—Mr. Tennant has stated that a soldier unlikely to be again fit for military service was retained in the military hospital as a free patient after discharge from the army if he required further hospital treatment.

Sanatogen.—Sir C. Kinnoch-Cooke asked the President of the Board of Trade, on March 30th, to explain the conditions under which the Sanatogen Company was permitted to trade in this country; and whether, in view of the increasing cost of milk, and seeing that in the district in which the sanatogen factory was situated there was a demand for milk owing to the increased influx of population engaged in munition and dockyard work, and that milk was largely used for the manufacture of sanatogen, he would consider the advisability of winding up the company and so free quantities of milk for consumption. Mr. Runciman said that the business of the Sanatogen Company was being carried on in this country under supervision. The Advisory Committee appointed under the Trading with the Enemy Amendment Act, 1916, already had the case under consideration, and inquiries were being made with regard to the points referred to. In reply to further questions, Mr. Runciman said that pending the receipt of the committee's report he did not think it advisable to take any further steps.

THE British Fire Prevention Committee (8, Waterloo Place, Pall Mall, S.W.) has prepared a small placard (No. 28) setting out the fire precautions which should be taken for working parties and voluntary aid organizations for war work.

A DEMONSTRATION of a life-saving waistcoat was given recently in the swimming baths at the Y.M.C.A. head quarters in London. It consists of two superimposed garments, the inner consisting of a single thickness of waterproof material and the outer of two such thicknesses with a layer of kapok—a form of short-stapled cotton-wool—between them. On sudden immersion the volume of air between the two waistcoats is forced by the water into the spaces in the upper part of the garment, where it is entrapped by the airproof and watertight fabric, thereby enabling the wearer to keep his head above water. Should any of the air escape owing to damage of the material, provision has been made for ensuring reserves of buoyancy by means of the kapok and the air enclosed with it between the two outer linings. Various tests were made on the occasion referred to, and the waistcoat acquitted itself quite satisfactorily, although a demonstration in a swimming bath scarcely affords a criterion as to what would happen at sea. One advantage of the "Ever-ready" waistcoat, as it is called by the makers, the Life-saving Devices Syndicate, Basilston House, Moorgate Street, London, E.C.4, is that it needs no inflation on emergency; it is worn continuously, adding somewhat to the bulk of the wearer, but not otherwise inconveniencing him.

THE WAR.

AMPUTATIONS AND AMPUTATION STUMPS.

The War Office has issued a little pamphlet entitled *Memorandum on Amputations and Amputation Stumps*.^{*} It brings together, for the benefit of medical officers serving in military hospitals at home and abroad, the experience gained by the surgeons at home who have been engaged in the after-treatment of amputation cases, more especially with regard to the fitting of artificial limbs. The notes, we gather, are founded upon the experience at the special hospital at Roehampton. The number of cases sent to it for artificial limbs is large, so that the opportunity for study and observation has been unusually favourable, and the conclusions reached undoubtedly deserve, as the introduction to the memorandum says, "the careful consideration of all operating surgeons." It is stated that of the cases which, as far as the condition of the wound goes, are ready for fitting, the stumps in many are more or less objectionable from the limb-makers' point of view.

Amputations.

The first section of the memorandum deals with amputations, and it is pointed out that while the site, and often the method, of an amputation is mainly determined by the injury, in many cases the surgeon is able to use his discretion not only in the matter of the immediate surgical condition, but also with regard to the future usefulness of the stump. As an example, it is said that while, as a general rule, the amputation stump should be made as long as possible, yet the longest is not always the most useful to the patient or the best for the fitting of an artificial limb. Amputation through a joint (below the shoulder or hip) leaves no room for the fitting of a joint at its proper level in the artificial limb, and it may therefore often be better to amputate just above a joint rather than through it, unless, of course, a still lower site is available. "Guillotine" amputation—that is, straight through the limb, or circular without flaps—is an excellent procedure in suitable cases, in order to secure the freest possible drainage with the least sacrifice of tissues, but it must be followed by the proper after-treatment—namely, secondary amputation as soon as the wound is clean. Cases in which these open stumps have been allowed to heal by granulation, or treated by skin grafting, have in some instances given results which have been extremely unsatisfactory. If the bone cannot be well covered eventually it is better to re-amputate than to allow the flaps to become drawn in, adherent, and distorted in the process of cicatrization.

These general principles are illustrated in paragraphs dealing with amputations at various levels in the upper and lower extremity. With regard to amputation through the leg, the fact is emphasized that kneeling stumps are extremely undesirable at the present day, and that therefore all stumps below the knee should be kept straight in extension and not allowed to become contracted. The best amputation through the hip-joint is said to be that by an anterior racquet, tying the main vessels in the first incision. To this section there is a note to the effect that a case of amputation has not yet been met with at Roehampton, either in the upper or in the lower extremity, to which it was not possible to fit an artificial limb.

Amputation Stumps.

In the second section, on amputation stumps, it is said that from the prosthetic point of view the chief requirements of a good stump are (1) a good covering for the bone; (2) sound healing; (3) consolidation; (4) painlessness; (5) freedom of movement. It is pointed out that consolidation of the soft parts continues for several months; if a bucket limb is applied prematurely it soon becomes loose and ill-fitting from shrinkage of the stump, and, as a general rule, four months should elapse from the date of amputation before any attempt is made to fit an artificial limb. During this period consolidation may be hastened, and the condition of the stump much improved by firm bandaging. The conditions which prevent or delay the fitting of an artificial limb are enumerated as (1) sinuses, (2) painful stumps, (3) unsound scars, and (4) contracture in the neighbourhood of the joint immediately above the amputation. With regard to painful stumps, it is said that

^{*} March, 1916, 40, Misc., 1320.

localized pain on pressure is nearly always due to a bulbous nerve-end near the end of the stump, but in some cases the nerve end is spread out and adherent to the bone or to the scar. As painful nerve-ends are not always evident to the patient until pain, which may be intolerable, is elicited by the pressure of the bucket, they should be sought for by the surgeon and removed before the artificial limb is fitted. In a note on the great frequency of painful bulbous nerve-ends the advice is given that the principal nerves should always be identified and cut short at the primary amputation. Diffused tenderness, on the other hand, is, except in recent stumps, usually due to periostitis or necrosis, the latter, of course, calling for operation. It is added that pain, either localized or diffuse, is sometimes due to bony spicules projecting from the end of the bone. Such osteophytic outgrowths are commonest in stumps about the middle of the thigh, and may have to be removed before an artificial limb can be worn. Speaking generally, it is said that in all amputations the object should be to get a linear scar placed where it will not be subjected to pressure or irritation by the artificial limb.

The memorandum, though short, will be found not only very helpful but very readable, for it deals primarily with general principles, and their application to particular conditions is always adequately explained.

CASUALTIES IN THE MEDICAL SERVICES.

On March 28th it was announced that, in the published lists of casualties, the seat of war in which the casualty occurred, and the battalion in which the officer or man was serving, would no longer be stated, for military reasons. Relatives were also asked not to publish these facts in obituary notices. This information, therefore, can no longer be given.

ARMY.

Died on Service.

Captain Frederick Francis German, R.A.M.C. (temporary), died at his residence, Bedford House, Sandy Road, Seaforth, Liverpool, on March 30th, aged 55. He was educated at Liverpool, and after taking the L.R.C.P. and L.R.C.S. at Edinburgh in 1881 he acted as junior house-surgeon of the Stanley Hospital, Liverpool, house-surgeon of West Bromwich District Hospital, and acting assistant-surgeon of His Majesty's prison, Liverpool. He then went into practice at Seaforth, where he took much interest in public life. In 1895 he became a member of the local council, and three years later its chairman, a position which he subsequently resigned to take up the post of medical officer of the Waterloo-with-Seaforth urban district. He was also honorary physician to the Waterloo and District Hospital, surgeon to the troops at Seaforth, and to the Lancashire county police, and medical examiner to the National Society for the Prevention of Cruelty to Children. He was a Captain in the Lancashire Artillery Volunteers, but resigned his commission in 1907, and had lately joined the R.A.M.C. as a temporary Captain. He was a prominent Freemason, being a P.Pr.G.W. of West Lancashire and a P.M. of the Skelmersdale Lodge No. 1380. In politics he was a Conservative. He leaves a widow, daughter, and son, the latter being a staff-sergeant in the Royal Field Artillery.

Wounded.

Captain R. H. Condy, R.A.M.C. (temporary).
 Captain Gross, R.A.M.C. (temporary).
 Captain A. Robb, R.A.M.C. (T.F.)
 Lieutenant J. Young, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Carter, Arthur Rowland, Sergeant Rhodesian Regiment, of Odzi Rapids Farm, South Rhodesia, eldest son of the late Deputy Surgeon Rowland Wimburn Carter, A.M.S., killed in action in February, aged 35.

Childe, Charles M., Captain Gloucester Regiment, eldest son of the late Lieutenant-Colonel L. F. Childe, I.M.S., killed recently. His commission as Captain was dated February 13th, 1915.

Kenyon, Charles Wilton, Second Lieutenant Royal Sussex Regiment, attached to a trench mortar battery, son of Dr. G. H. Kenyon, of Horsham, Sussex, killed in action on March 16th, aged 22. He was born at Horton Pagnell, in Yorkshire, in 1893, educated at Reigate and at Horsham Grammar Schools, and at Exeter College, Oxford, where he was in the O.T.C. His commission was dated November 13th, 1914.

King, Maurice Edmund, Second Lieutenant Middlesex Regiment, third son of the late Dr. Henry W. King, of Northwood, Middlesex, killed recently, aged 19. He was educated at

the Leas, Hoylake, and at St. Edward's School, Oxford, and had just completed his first year as a medical student at University College Hospital when the war began. He was in the Rugby fifteen both of his school and hospital. His commission was dated February 23rd, 1915.

Bruce, Vincent Connell, Lieutenant Gordon Highlanders, second surviving son of the late Dr. Alexander Bruce, of Edinburgh, missing since March 26th, and believed killed, aged 27. He was educated at New College, Oxford, and at Edinburgh University, where he took the degree of LL.B. just before the war. He enlisted at the beginning of the war in the 15th Royal Scots and got his commission as second lieutenant in the 13th Battalion of the same regiment on November 13th, 1914, subsequently transferring to the Gordon Highlanders. On attaining his majority he succeeded to the estates of Inverquhomery and Longside in Aberdeenshire.

MEDICAL STUDENT.

Dorman, Thomas Robert Hobart, Lieutenant 2nd Battalion Royal Munster Fusiliers, who is reported missing since March 1st, 1916, is the son of the late Major Thomas Dorman, R.A.M.C., of Kinsale, co. Cork. He was a third year medical student at Trinity College, Dublin, and joined the army in March, 1915.

NOTES.

In succession to Sir Arthur Lawley, who has accepted another appointment, the Earl of Donoughmore has been appointed British Red Cross Commissioner in France to work under Sir Arthur Sloggett, D.G., A.M.S., and Chief Commissioner in France for the British Red Cross Society and the Order of St. John.

HONOURS.

On March 30th a long list of honours was published: six V.C.'s, twelve D.S.O.'s, seventy Military Crosses, and 203 awards of the Distinguished Conduct Medal. At the same time a number of decorations, conferred by the President of the French Republic, were gazetted. Quartermaster and honorary Lieutenant E. Lyall, R.A.M.C. (T.F.), received the D.S.O.; and Captain B. Grellier (S.R.), temporary Captains L. D. Saunders and H. V. White, and temporary Lieutenant J. A. Harper, all of the R.A.M.C., got the Military Cross.

D.S.O.

Quartermaster and honorary Lieutenant Edward Lyall, 2nd Northumbrian Field Ambulance, R.A.M.C. (T.F.), (attached 185th Tunnelling Company, R.E.). For conspicuous gallantry and devotion to duty. When a large camouflet was blown in by the enemy he hurried through a flooded gallery in the dark and under heavy fire went for proto apparatus. Finding all the proto apparatus already in use, he hurried on and, although in an exhausted state, descended a shaft without any apparatus, assisted in the rescue of an officer, and then went further, rendered aid to two men, and made a most gallant effort to save two officers.

Military Cross.

Captain Bernard Grellier, R.A.M.C. (attached 10th Royal Welsh Fusiliers). For conspicuous gallantry and devotion to duty during operations when tending the wounded under heavy shell fire. He helped to dig out wounded men who were buried.

Temporary Captain Leonard Douglas Saunders, R.A.M.C. (attached 10th Notts and Derby Regiment). For conspicuous gallantry and devotion to duty. He tended the wounded under heavy fire, and finally evacuated them all with great skill and care. His clothing was torn by fragments of shell, and he was at work for forty-eight hours without a rest. This is the third time he has displayed great coolness and devotion to duty.

Temporary Captain Harry Vere White, M.D., R.A.M.C. (attached 7th Lincs Regiment). For conspicuous gallantry and devotion to duty during operations when tending the wounded. His dressing station was repeatedly hit by shells, and he himself was severely knocked about several times, but for thirty-six hours he stuck to his work.

Temporary Lieutenant John Alexander Harper, M.B., 52nd Field Ambulance, R.A.M.C. For conspicuous gallantry when leading stretcher-bearers during operations. On one occasion, when three of his bearers were wounded, he went alone, under heavy shell fire, to the aid post.

Distinguished Conduct Medal.

Sergeant J. W. Cherry, R.A.M.C. (T.F.), 1/3rd Northumbrian Field Ambulance.

Sergeant W. J. Currie, R.A.M.C., 59th Field Ambulance.

Corporal D. H. Molyneux, R.A.M.C., 53rd Field Ambulance.

Private J. J. Filton, R.A.M.C., 59th Field Ambulance.

Private C. M. T. Sheriff, A.S.C., attached 53rd Field Ambulance.

Legion of Honour: Grand Officer.

Surgeon-General Sir A. T. Sloggett, K.C.B., A.M.S. (substituted for the Cross of Commander, the award of which was gazetted on November 8th, 1915).

Croix de Guerre.

Lieutenant-Colonel J. Mill, R.A.M.C. (T.F.).

Captain J. A. Cullum, Canadian A.M.C.

Captain G. H. R. Gibson, Canadian A.M.C.

Captain E. D. Gairdner, R.A.M.C. (T.F.).

A list of naval officers mentioned in despatches, by Rear Admiral Sir Dudley de Chair, for good service in the patrol cruisers, includes the name of Staff Surgeon Robert Bernard Scribner, R.N.

THE RICHMOND HOME FOR HELPLESS MEN.

The Star and Garter Home at Richmond for incurably helpless soldiers and sailors has now provision for 65, and the number already admitted is 49. A lift to the garden in which beds can be taken out on to the terrace will, it is hoped, be completed by the end of the month. The consulting staff is as follows: Consulting physician, Sir David Ferrier, F.R.S.; visiting physician, Dr. S. A. Kinnier Wilson, F.R.C.P.; consulting surgeon, Mr. Wilfred Trotter, M.B., F.R.C.S.; consulting urologist, Mr. J. Thomson Walker, M.B., F.R.C.S.; consulting ophthalmic surgeon, Dr. A. C. Hudson, F.R.C.S.; honorary dentist, Mr. Donald Campbell. The association called the British Women's Hospital is collecting £65,000 for the new buildings, but there is as yet no endowment.

MEDICAL OFFICERS WANTED.

8/3rd H.C. Field Ambulance, R.A.M.C.(T.).

Two or three vacancies exist for medical officers. Those desirous of joining this unit should make immediate application to the C.O. at the head quarters, "Trenches," Redhill. (Phone 300 Redhill.)

England and Wales.

MANCHESTER INFECTIOUS HOSPITALS.

EXTENSION schemes in connexion with the Infectious Disease Hospitals of the Manchester Corporation are now almost completed. The accommodation at the Monsall Fever Hospital has often been taxed to the utmost, and not infrequently cases have had to be refused. Five new blocks have now been added, four containing twenty-four beds each, with small observation wards and wards for special isolation cases; the fifth block provides extra nurses' accommodation. Additions have also been made to the laundry, and a shed for the motor ambulance has been built. Altogether there will be additional accommodation for 112 patients, and it is intended that in future all ordinary cases of infectious disease shall be taken to Monsall, so that the Baguley Hospital may be free for tuberculosis cases. The extensions at Baguley provide 100 beds for men and 52 for women. The new wards all face south and are open to the air above the windows, protection from storms being by means of inclined weather boards; on the north aspect there is protection for the lower story by a projecting balcony and for the upper story by the roof which is carried forward. A new dispensary, a dental room and a laboratory, and a new recreation and dining room have also been provided.

INSPECTION OF LYING-IN HOMES IN LONDON.

At the meeting of the London County Council on April 4th a long debate took place on the proposed delegation to the metropolitan borough councils of power to inspect lying-in homes under the provisions of Part IV of the London County Council (General Powers) Act, 1915. It was reported that since registration became compulsory under this Act 138 applications for registration of lying-in homes had been received, nearly one-third being for homes in Wandsworth and St. Marylebone. The result of such preliminary inspections as had already been made showed that the issues involved related almost entirely to the structural or sanitary fitness of the premises, therefore it was thought that the work was one for the Public Health Committee, and that the inspection should be carried out under the direction of the medical officer. Two of the borough councils—Bermondsey and Camberwell—stated that they were not prepared to undertake inspection; the remainder very generally stated that they could carry out the inspection with their existing public health staff without incurring additional expense. Most of the charitable and social welfare organizations strongly deprecated delegation of its powers by the Council, and eventually it was agreed that the Council itself should proceed with the work of inspection, the inspection to be undertaken by the Council's medical officer of health.

Scotland.

At a meeting of the directors of the Royal Blind Asylum and School, Edinburgh, on March 27th, the chairman said that the proposal to use Newington House as a residence for blinded soldiers had aroused great patriotic interest throughout Scotland. It was felt that it was very much

better that men who suffered this misfortune should live and work among their own people.

MAIMED SOLDIERS AND SAILORS.

The proposal to establish in the West of Scotland a hospital for soldiers and sailors who have lost limbs took definite shape at a meeting in Glasgow on March 29th. Subscriptions amounting to over £20,000 have been received, and Erskine House having been placed at the disposal of the promoters by Mr. Thomson Aikman, it is hoped that the committee will be in a position to receive patients within a few weeks. Lord Newlands, in moving a resolution appointing a committee, said that the credit for having initiated a movement for the benefit of soldiers and sailors who had lost their limbs was, so far as Scotland was concerned, due to Lady Issobel Douglas-Home, who started the Edenhall Hostel, Berwickshire, where valuable practical experience had already been gained. Sir William Macewen, in giving an account of the movement from its inception, said that notwithstanding the excellent work done at the Edenhall Hostel and at the Rochampton Hospital, it was apparent that there was abundant room for the establishment of another hospital to receive and treat men who had lost their limbs, or who had faulty use of their injured limbs after their discharge from the general hospitals, and to fit the limbless with artificial limbs and teach them to use them. Opportunity would be taken while the men were in hospital to inquire into their circumstances, and to help them to acquire knowledge, physical and mental, which would aid them in their future occupation. They would be taught to employ their spare time in useful and remunerative work, and those of dexterous hand and intelligent mind might be turned into artificial limb makers. Every effort would be made to fit them to earn their own living, and communications would be established with county representatives and with industrial firms, so that they might be distributed wherever suitable work could be obtained. The hospital is to be known as the Princess Louise Scottish Hospital for Limbless Soldiers and Sailors. Further donations will be received by the Lord Provost of Glasgow.

Ireland.

THE King has appointed Mr. Charles Yelverton Pearson, M.D., F.R.C.S., Professor of Surgery in University College, Cork, to be one of H.M. Honorary Surgeons in Ireland, in the room of the late Sir Charles Bent Ball, M.D.

The action in which Dr. Charles Ronayne, Youghal, claimed damages from Mr. Denis Doyle, U.D.C., for libel, was concluded at the Cork Assizes on March 28th. The alleged libel consisted of statements to the effect that plaintiff, who was dispensary doctor of Youghal, was incompetent and incapable of performing his duties. The defendant alleged that Dr. Ronayne was deaf, and in the interest of the sick poor he desired that he should retire on full pension. The jury found for the plaintiff in the sum of £100 and costs.

At a meeting of the Finance and General Purposes Committee of the Dublin Castle Red Cross Hospital it was reported that there were at present 126 wounded men in the hospital, and that since its opening 1,386 non-commissioned officers and men had been treated in the wards. The resident medical superintendent (Dr. W. K. Carew) reported that a new ward, containing ten beds, had now been fully furnished and equipped, so that 260 beds were available. An appeal is made for gifts of vegetables, potatoes, rhubarb, jam, cigarettes, tobacco, and slippers. A letter was read from the Belgian Consulate expressing thanks for the facilities placed at the disposal of Colonel Collins and Dr. Molder for the purpose of examining Belgian invalided soldiers.

At the Ballinrobe Quarter Sessions Dr. Hawkshaw claimed from the local board of guardians £3 3s. for duty performed for three days as locum tenens for Dr. Corcoran. The guardians were willing to pay the amount, but the Local Government Board insisted that the usual fee for three consecutive days was £2 2s. The doctor's demand was based on the scale fixed by the Mayo branch of the Irish Medical Officers' Association, and Judge Doyle gave a decree for the full amount, holding that it was reasonable.

Canada.

SUMMER COURSES IN MEDICINE.

IN view of the need for military medical officers, the medical colleges of Canada have decided to give special summer courses this year, so that fifth-year students may graduate at the end of 1916 instead of in the spring of 1917. Some months ago the students requested that such a course might be given, and at first the faculties of medicine were somewhat averse to crowding the work of the final year into a six months' course. The matter was placed before the medical faculties in a letter from the military authorities, asking if such courses could be given provided it could be shown that the military necessity existed for such action; when later it was indicated that this necessity did exist, the universities at once expressed their willingness to accede to the request. The Universities of Toronto, Queen's, and McGill have already announced such courses for this year, and it is probable that other medical colleges will do the same. This means, of course, a period of fifteen months of continuous study for the student and for the teacher continuous teaching for a period of twenty-three months, since another session of eight months must be entered upon after the production of the present final year men. A short vacation will be given during the hot part of the summer. The students will enlist for service immediately after graduation.

CANADIAN MILITARY HOSPITALS COMMISSION.

The first *Bulletin* of the Military Hospitals Commission contains a full account of the purpose and work of the Commission and its co-operating associations, with a statement of the regulations governing pay, subsistence allowance, marriage, and other matters concerning the members of the Canadian Expeditionary Force. The Commission was formed by Order in Council dated June 30th, 1915, for the purpose of providing convalescent homes and medical treatment for returned invalided and wounded members of the force. Shortly afterwards the benefit of such treatment was extended to men who had enlisted but had not yet left Canada, and later the powers of the Commission were extended to the vocational re-education of those soldiers who through disability were unable to resume their former occupations. This phase of the work was placed in the hands of provincial commissions, which in turn elected local committees. Voluntary welcome and aid committees have also been formed in numerous districts, some of which render financial assistance to the men and their families. Convalescent homes have been opened at Sydney, Nova Scotia; St. John, New Brunswick; Quebec, Montreal (3), and St. Agathe des Monts, in the province of Quebec; Kingston (2), Toronto (2), Hamilton (2), Ottawa, London, and Port Arthur, in the province of Ontario; Winnipeg, Manitoba; Calgary, Alberta; Regina, Saskatchewan; and Esquimalt, British Columbia. At the present time there are about 1,200 men at these various homes. Upon examination by the Medical Board at the discharge dépôt the men are classified as follows:

Class 1.—Men for immediate discharge without pension:

- Unfit for overseas service, but capable to take up their previous civilian occupation.
- Disability not the result of service or involving claim as the result of or aggravation by service.

Class 2.—Men whose condition may be benefited by further medical treatment or rest in a convalescent home, hospital, or sanatorium.

Class 3.—Men having a permanent disability which would not be benefited by further medical treatment (such disability due to or aggravated by service) and whose cases will immediately be considered by the Pensions Board with a view to pension.

Before leaving the discharge dépôt the men are provided with suitable clothing, and are given a sum of money sufficient for immediate needs (not more than 10 dollars); the remainder of the money to which the man is entitled is forwarded to the paymaster of the district to which he is going. The rate of pay for a private is 1 dollar a day, with 10 cents field allowance; the subsistence is from 60 to 85 cents a day.

The functional and vocational re-education of disabled men is the most difficult branch of the work of the Commission. The secretary is Mr. T. B. Kidner, who has had a good deal of experience in such work both in England and Canada. The establishment of schools has been commenced in connexion with the convalescent homes, and

preliminary instruction is given to the men in general education and recreative manual work. Such classes will be open to all the men at the convalescent homes. The Commission is conferring with the provincial governments with a view to the formation of a definite land settlement scheme, as it is expected that a considerable number of men will be anxious to take up land rather than return to their former occupations.

The Commission has agreed to recognize the British and other allied army and navy reservists who have left Canada during the period of the war for naval service. These men will be treated exactly as members of the Canadian Expeditionary Force, and will be given free treatment in a convalescent home if they require it.

Correspondence.

ARMY STANDARDS OF VISION.

SIR,—In a note on "The Relation of the Eyes to Rifle Shooting" in the *JOURNAL* of April 1st the statement occurs: "The army standard of vision is not high, and many soldiers require glasses to enable them to shoot with any degree of accuracy." We assume that the present British army standard of vision for recruits is referred to, and as a great deal of misunderstanding seems to be prevalent in regard to this point, we feel that it is very important that the facts should be made widely known. The present British army standard for general service requires vision of $\frac{5}{8}$ at least in each eye, or $\frac{5}{8}$ in the right and $\frac{6}{8}$ in the left *without glasses*. In the armies of France, Italy, Germany and Austria the visual standards very closely resemble each other while differing fundamentally from our own. They require for combatant service vision of about $\frac{5}{8}$ at least in the better eye *with glasses* (if necessary), which, if concave, may not exceed 6 to 7 dioptries in strength. To the uninitiated it might appear as if the British standard were lower than the others, but a moment's consideration will show that it is, on the contrary, by far the highest. The vision of a man who has 6 dioptries of myopia, even if his sight with glasses is excellent, is very seldom more and is often less than $\frac{5}{8}$ without glasses. Conversely, vision of $\frac{5}{8}$ corresponds on the average to a myopia of about 2.5 dioptries. The true comparison is therefore between the British $\frac{5}{8}$ and the Continental $\frac{5}{8}$ or the British 2.5 dioptries of myopia and the Continental 6 dioptries.

In respect of target shooting, it has been shown by various Continental writers that the best results are obtained by the soldiers who have the best vision, whether obtained with the aid of correcting glasses or not.—We are, etc.,

JAMES V. PATERSON, F.R.C.S. Edin.,
Ophthalmic Surgeon, Royal Infirmary;

H. M. TRAQUAIR, F.R.C.S. Edin.,
Assistant Ophthalmic Surgeon, Royal Infirmary.

Edinburgh, April 3rd.

Obituary.

JOHN T. LEON, M.D. LOND., M.B., B.Sc., D.P.H. CAMB.;
CAPTAIN R.A.M.C. (T.); HONORARY ASSISTANT PHYSICIAN, ROYAL
PORTSMOUTH AND GOSPORT HOSPITAL; S.S.O. PORTSMOUTH
COMMAND.

DR. JOHN T. LEON, the esteemed Chairman of the Portsmouth Division of the Southern Branch of the British Medical Association, died in the afternoon of March 31st, aged 50, from cerebro-spinal fever. He was almost certainly infected by a patient who coughed in his face during swabbing of the throat, and thus fell a martyr to his devotion to duty. Throughout his illness he was attended by his friends, Lieutenant-Colonel Routh and Major Ridout, and his brother-in-law, Dr. Luff of St. Mary's Hospital, saw him frequently in consultation. Dr. Leon's commission as Captain R.A.M.C. (T.F.), attached to the 5th Southern General Hospital, was dated July 21st, 1908. When on duty at the Alexandra Hospital, Cosham, he undertook much special work of high value, including the bacteriology of the instructive series of cases reported in the *JOURNAL* of February 26th, p. 307, in Captain Culpin's article on "The diagnosis of abortive cerebro-spinal meningitis."

Dr. Leon was educated at Clifton, and afterwards in Germany. He then entered University College, London, where he was Tufnell Scholar in 1885, and in 1887 he graduated B.Sc. in the University of London. In 1890 he was appointed assistant lecturer on physics and demonstrator of chemistry in St. Mary's Hospital Medical School. After holding those appointments for three years he began the study of medicine at St. Mary's, where he had a distinguished career. He became M.R.C.S. and L.R.C.P. in 1895, and graduated M.B.Lond. in 1896 and M.D. in 1899. After qualifying he was appointed on plague duty in India, where he did useful work in collaboration with Dr. Haffkine. Subsequently he served throughout the South African war, and was for the greater part of the time attached to No. 8 General Hospital at Bloemfontein. On his return from South Africa he settled in practice at Southsea, where he soon gained a leading position. He took the D.P.H. of Cambridge in 1897, and had acted as deputy to the M.O.H., Dr. Mearns Fraser, during temporary absences. Dr. Leon had been for a long time actively associated with the Royal Portsmouth Hospital, and at the time of his death was senior assistant physician. He was a Fellow of the Royal Society of Medicine, and vice-president of the Section for the Study of Disease in Children. In 1896 he contributed to this JOURNAL a note "On the relative opacity of calculi to α rays," illustrated by skiagrams of oxalate, phosphate, triple phosphate and uric acid calculi. He was keenly interested in social questions, and amongst other philanthropic work he acted as honorary secretary of the local branch of the Victoria Nursing Association. He was a brave man, who worked unsparingly for his country, and in him the medical profession has lost a distinguished physician and an able bacteriologist. Captain Leon leaves a widow and two young children, with whom much sympathy is felt.

MANY naval officers and St. Bartholomew's men of the early Eighties will hear with regret of the death of CHARLES STRICKLAND, which occurred after nine months' illness borne with great patience. He entered the medical profession rather later than most of his contemporaries, as he had been obliged to live for some time in South Africa on account of pulmonary tuberculosis, the disease which recurred last year. He took the diploma of L.R.C.P.Lond. in 1885, and that of L.R.C.S.Edin. in the following year. Strickland had a happy disposition, thoroughly enjoyed his life, and his genial nature made him a social success both at the hospital and in the services. When the war broke out he was fleet surgeon at the Royal Marine Light Infantry Barracks, Forton. Soon after this he was placed on the retired list on account of age, but he remained at this post until ill health necessitated sanatorium treatment. After an unsuccessful trial of this régime he settled down with his sister in a house in Southsea which he had prepared and looked forward to as his home on retirement; there he died somewhat suddenly on March 25th at the age of 56. The funeral, a naval one, took place on March 31st at the Highland Road Cemetery, Southsea.

* With distinction in Physiology.

UNIVERSITY OF DURHAM.

THE following were among the degrees and diplomas conferred at the Convocation on March 25th:

M.D. (for Practitioners of Fifteen Years' Standing)—H. B. G. Newham, S. A. Mittampalam.

M.B. and B.S.—A. F. R. Dove, H. K. Graham-Holmes, E. Haigh, G. Irving, A. E. Raine, A. Smirhwaite, B. Welch.

B.Hy. and D.P.H.—B. G. H. Connolly (*in absentia*), W. Grant.

UNIVERSITY OF ABERDEEN.

WAR SERVICE.

IN the course of his address at the graduation ceremony in the Mitchell Hall, Marischal College, on March 28th, the Principal gave the following statistics as to the number of persons belonging to the university who were serving in the naval and military forces. "Of our administrative teaching and research staffs, which in normal times numbered just over 100, 57 have been or are working directly for the purpose of the war. Of these, 15 are in the combatant service; 17 have commissions in the R.A.M.C. (8 beyond and 9 still within the university); 21 hold military offices of other kinds (6 of these with commissions), one is a prisoner of war, while there are several others who have attested but have not yet been called up. Of our graduates, 890 are commissioned, 253 in the combatant service, 604 in the R.A.M.C., and at least 33 as chaplains; and 161 graduates are still enlisted, making a total of 1,051 graduates on naval and military service. But that number does not include our graduates who are in charge of Red Cross hospitals, of whom 28 have been reported, nor about 30 others entered on the navy list as surgeons and agents at sick quarters. Add these and we have over 1,100 graduates in all on war duties. The exact number of our ungraduated alumni on service cannot be ascertained, but 71 have been reported as holding commissions and 63 as serving in the ranks—in all 139. Of undergraduate students, 121 have been commissioned and 237 have served or are serving in the ranks. Altogether I reckon that about 358 students have entered on service with the colours since the war began; and by the summer term this number will be increased. The total of graduates, alumni, students, staff, and servants of the university on active service is therefore about 1,580, as compared with 1,200 at last graduation. If we add to them the members of our Officers' Training Corps and our graduates who are serving as volunteers or under the Red Cross Society, and at naval sick quarters, we get about 1,700 as a grand total of those on war service or under training. That number does not

include 25 or 30 young men who would have matriculated as students but for their call to arms.¹

The Aberdeen University Work Party, organized in the department of materia medica by Professor Cash and a committee of ladies, had been able to dispatch large quantities of surgical dressings and hospital garments to the Red Cross and medical institutions connected with the army.²

When the Principal had concluded his address he read out the names of seventy members of the university who had given their lives. Each, he said, had joined the services because the hand of God was upon his conscience in the strength of the most sacred cause to which his country was ever called.

In an earlier part of his address the Principal referred to the postponement of the institution of certain lectureships. This reference recalls the fact that several important benefactions have recently been announced in the departments of medicine and science. These include the foundation by Sir Alexander McRobert, LL.D., of Cawnpore, India, of a lectureship in pathology with special reference to malignant disease. The emoluments of the lectureship will amount to about £750 per annum. The late Mr. William Jackson, Aberdeen, has bequeathed one-half of the residue of his estate towards the establishment of a chair of engineering in the university, the bequest being subject to his widow's life-rent. Mr. George S. Yuill, Australia, has handed over a sum of £4,000 to found travelling and other scholarships in chemistry, with special reference to its practical application to the manufactures and industries of Great Britain. A bequest by the late Miss Anne H. Cruickshank, daughter of a former professor of mathematics in the university, will shortly become operative. Miss Cruickshank left £10,000 for the purpose of founding a chair or lectureship in astronomy, and the revenue from this and other funds available will be sufficient to provide an annual return of £600.

Conferment of Degrees.—The following were among the degrees conferred:

M.D.—A. D. Pringle, M.B. (commended for thesis).
M.B., Ch.B.—*R. D. Lawrence, M.A., *A. G. Reid, W. Alexander, J. Anderson, Mary A. Chalmers, A. J. Hawes, A. A. Hearne, S. Henry, Eva C. Innes, B. S. Kanga, T. S. Law, A. A. MacKenzie, C. W. Macpherson, W. J. Moir, T. O. Robson, A. E. B. Sims, F. Simmes.

* With second-class honours.

† Passed Fourth Professional Examination with "Much Distinction."
‡ Passed Fourth Professional Examination with "Distinction."

Prizes.—The following prizes were presented:

Five Jameson memorial gold medal in anatomy: Violet M. G. Smith.

Keith gold medal for systematic and clinical surgery: A. G. Reid.

Shepherd memorial gold medal for systematic and practical surgery: Douglas S. Scott.

Dr. James Anderson gold medal and prize of £5 in clinical medicine: A. G. Reid and T. O. Robson proxime accessit.

Matthews Duncan gold medal in obstetrics: G. R. McRobert.
The Alexander Ogston prize in surgery: F. W. Carter.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONY.

In his address to the new graduates at the graduation ceremony on March 28th, Sir Thomas Fraser, who presided, after a reference to the loss the university had sustained by the death of Sir William Turner, turned to the effect of the war. The number of matriculated students, although materially lessened, had not, he said, been disastrously affected, as appeared to have happened in some of the English universities. In 1913-14 there were 2,731 male students, and in 1914-15 there were 1,941. Comparing the numbers from the beginning of 1914-15 to March 11th, 1915, with those for the same period in 1915-16, the figures were in the former 1,732 and in the latter 1,222. He hoped that in future sessions women would be represented not only in undiminished, but in greater numbers. The number of graduates and students who had already joined the services was about 4,400; of these, 145 had been killed in action or died on service, 126 had been wounded, 2 were missing, and 8 were prisoners. Military honours and decorations had been conferred on 77, and 90 others had been mentioned in dispatches. The training all the alumni had undergone had had a gratifying effect both physically and mentally, and he thought that those great benefits might be continued after the war were physical training regarded as being within the scope of university education. He suggested that a university hall or other building devoted to athletic exercises should be erected, on the walls of which the names of those alumni who had given their lives for the country and empire should be inscribed. The gymnasium he had in view should be under the direction of a scientifically qualified expert with university status able to decide on the appropriate form and extent of the physical training required by each student. Enlightened benefactors of such a movement would place Edinburgh University on an equality of advantage with other Scottish universities, for gymnasia had already been provided, largely by public benefaction, in Glasgow, Aberdeen, St. Andrews, and University College, Dundee.

Conferment of Degrees.—The following degrees were conferred:

M.B., B.S.—K. P. Brown, C. A. E. I. Brownlee, *A. J. Caird, Yun Ying Chan, F. W. Clark, O. T. I. Clarke, A. Cleland, A. A. Crawford, B. G. Crawford, H. J. Davidson, J. Dickson, *A. V. Dill, Thea Do, W. H. Ferguson, G. H. Fraser, Bhaskar Balwantrao Gadgil, J. A. C. Gny, C. Harris, J. E. Hill, J. M. Johnston, E. B. Kelley, J. B. F. M'Laron, J. C. Manuel, G. Morris, Matheson

Sankara Narayana, †D. H. Paterson, Pierre Ange Rostant, J. J. Shannon, N. H. Smith, D. R. Thomas, A. F. de Waal, Gladys Ward, J. M. Watt, †H. D. Wright.

* With first-class honours † With second-class honours.

UNIVERSITY OF GLASGOW.

The following candidates for the degrees of M.B. and Ch.B. have passed in the subjects indicated:

[B., botany; Z., zoology; P., physics; C., chemistry; A., anatomy; Ph., physiology; M., materia medica and therapeutics; Path., pathology.] *A. P. Agnew (Z., C.), A. G. Aitken (Z., C.), W. S. Aitken (Z., C.), D. E. Alley (B.), A. A. Bain (Z., C.), A. Baird (Z.), A. Barr (Z.), A. M. Beaton (Z.), A. R. Black (P.), J. T. Blundell (Z.), G. H. Boyd (Z., C.), A. O. Bruce (Z.), G. F. Cables (Z.), S. Caldwell (Z., C.), P. A. Carrie (Z., C.), A. Chisholm (Z., C.), D. H. Clutterbuck (C.), H. Collingbourne (C.), A. B. Cook (B., Z., C.), W. Davie (Z.), J. Dawson (Z., C.), J. Dewar (Z.), A. S. Dick (Z.), J. M. Duff (Z.), W. N. Duguid (Z.), T. Fletcher (Z., C.), J. C. Forsyth (Z., C.), B. P. Gardner (B., C.), T. Gibson (Z., C.), *R. D. Gillespie (Z., C.), C. Glen (Z., C.), G. G. Graham (C.), A. Gray (Z., C.), J. L. Halliday (Z., C.), D. R. Hamilton (Z., C.), W. M. Hamilton (P.), D. Henderson (Z., C.), W. C. Holdsworth (Z., C.), W. Houston (Z., C.), A. D. Humble (B., P.), J. Harwick (Z., C.), G. Jamieson (C.), L. M. Johnston (Z., C.), J. L. Kennedy (Z., C.), D. A. Ker (Z., C.), W. P. D. Kerr (Z., C.), J. C. Kirkwood (Z., C.), D. Lamont (Z., C.), J. Lavelle (Z.), A. Logan, M.A. (B.), A. L. M'Adam (Z., C.), G. M'Alpine (B., P.), C. G. H. Macartney (Z., C.), H. J. M'Bride (Z., C.), M. M'N. M'Bride (B., P.), W. M. M'Cash (Z., C.), A. M. M'Clure (Z., C.), J. M'Court (B.), R. M'Courtney (B.), D. Macdonald (Z., C.), J. Macdonald (Z., C.), T. S. Macdonald (Z., C.), J. M'Dougall (Z., C.), J. Macfarlane (Z., C.), T. J. M'Kail (Z., C.), W. M'Kendrick (Z., C.), S. R. M'Kim (B., Z.), O. T. MacLaren (Z., C.), J. M'Nair (Z., C.), J. C. M'Naught (Z., C.), R. M. Macpherson (Z., C.), M. P. G. Main (Z.), A. Markson (Z., C.), E. B. Miller (Z., C.), J. M. L. Mitchell (Z., C.), *G. W. Murray (Z., C.), J. Nairne (Z., C.), J. P. Neilson (C.), M. Nicolson (Z., C.), G. S. P. Noble (Z.), A. L. Orr (Z., C.), T. C. Porter (C.), A. H. Rankin (Z., C.), P. G. Rankin (P.), J. Reid (Z., C.), J. F. Reilly (Z., C.), C. G. Richards (Z.), J. Sachs (Z., C.), W. H. Scott (Z., C.), H. E. Seiler (Z., C.), H. J. Sheppard (Z., C.), A. G. Smith (Z., C.), D. C. Smith (Z., C.), A. Snaddon (Z., C.), J. Snaddon (C.), F. C. Speechley (C.), A. V. Steen (Z., C.), D. Stewart (Old Ord.) (B.), D. Stewart (Z., C.), *J. M. L. Strang (Z., C.), W. D. Sutherland (Z., C.), A. Symon (Z., C.), A. S. Taylor (Z., C.), C. N. Teuppe (Z.), W. L. Templeton (Z., C.), J. N. Tennant (Z., C.), D. W. Tobias (Z., C.), G. Tudhope (Z., C.), P. A. Walker (B., P.), J. D. Whiteford (C.), C. B. Whitte (Z., C.), *J. Willic (Z., C.), J. Yule (Z., C.), Annie M. Alexander (Z.), Marion B. Arnsperg (Z., C.), *Mary Baird (Z., C.), Margaret Bennett (Z., C.), Elizabeth M. V. H. B. Bird (Z., C.), Margaret W. Blackwood (Z., C.), Agnes L. D. Bradford (Z., C.), Susan S. Bryce (Z., C.), Lilias E. B. Buchanan (Z.), Annie B. Cameron (P., C.), Edith Chalmers (C.), Ellen B. Cowan (Z.), Edith M. Davidson (Z.), Simcine Denil (Z., C.), Isabella G. Dunlop (B.), *Elsie F. Farquharson (Z., C.), Elizabeth J. Findlay (Z., C.), Christian M. Fleming (Z., C.), Margaret E. Gibson (Z.), Muriel M. Gilmour (Z., C.), Agnes S. Glover (Z., C.), Mabel S. Goudie (B., Z.), Mary B. Grant (Z., C.), Christina Gray (Z., C.), Brunhilde M. Grieve (Z., C.), Agnes B. Hart (Z.), Marion P. Hogg (B., P.), Isabel E. R. Jeffrey (C.), *Margaret L. Johnston (Z., C.), Jane C. MacDonald (Z., C.), *Mary J. Macfarlane (Z., C.), Annie I. C. MacLardy (C.), *Alexandrena M. MacLennan (Z., C.), Marie J. M'Naught (C.), Muriel M. M'Walter (C.), Janet D. Montgomery (Z., C.), Effie Niblock (Z., C.), Alice J. Paton (B.), Joanna T. Rae (Z., C.), Isabel Reid (Z.), Kathleen E. H. Rutherford (Z., C.), Mary Russell (Z., C.), Marguerite L. Sclanders (Z., C.), Margaret D. L. Service (Z., C.), Catriona Sinclair (Z., P.), Elizabeth H. M. Slimmon (Z., C.), Alexandra W. Smylie (Z., C.), Jane E. Stewart (Z., P., C.), Christina S. Stoddart (Z., C.), Margaret M. Stuart (Z.), Dorothy M. Summers (Z.), Helen B. Sutherland (Z., C.), Margaret Y. Turnbull (Z.), *Mary C. Walker (Z., C.), Mary L. Wilson (Z., C.), *Helen F. Wingate (Z., C.), Agnes H. M. Young (Z., C.).

C. O. Anderson (A.), A. B. Austin (Path.), R. Bethune (M.), A. Black (M.), D. O. Bowie (Ph., M.), J. Bradford (Path.), *A. D. Brown (A., Ph.), M. J. Cahalane (M.), T. W. Carstairs (Ph.), M. Chalmers (A.), A. E. Cochrane (M.), H. A. Cochrane (M.), A. C. Connell (A., Ph.), E. M. E. Cumming (A., Ph.), W. Dempster (M., Path.), J. C. Dow (A., Ph.), A. B. S. Drysdale (M.), K. H. Dyke (M., Path.), D. Finlayson (M.), J. P. Fleming (M.), T. Fleming (M.), T. Forrest (M.), A. D. Fraser (A.), K. J. A. Gillanders (M.), W. H. Gordon (Path.), A. S. Goudie (M.), P. F. A. Grant (A., Ph.), J. S. M'P. L. Gray (M.), J. G. Harrower (M.), A. Henderson (M.), J. Hislop (M.), T. J. Honeyman (Path.), M. Hyman (M.), E. P. Irving (Path.), J. Irving (M.), J. Joels (M.), B. E. Kerr (M.), W. H. Kerr (M.), W. M. Kerr (M., Path.), J. P. Kilty (M.), A. B. M'K. Lang (Path.), G. Lean (Path.), J. Liddell (M.), J. Lipschitz (M.), F. R. Lubovius (Path.), W. W. Lunde (Path.), *A. J. Macartney (A., Ph.), D. MacColl (A., Ph.), H. E. M'Coll (M., Path.), A. B. Macdonald (A., Path.), B. T. M'Gibbon (M.), A. D. C. M'Gowan (Path.), T. M'Gowan (M.), J. A. C. MacGregor (M.), D. B. M'Intosh (Path.), J. W. Mackay (M.), D. W. M. MacKenzie (M., Path.), R. H. M'Killip (Path.), J. G. M'Kinna (A., M.), J. M. Mackintosh (Path.), W. S. L. M'Leish (M.), J. Macleod (A., Ph.), W. M' Linden (M.), F. K. Macmillan (A., Ph.), D. Macqueen (M., Path.), A. W. M'Roie (M.), J. M. Melvin (M.), G. A. Mitchell (Path.), W. Napier (M.), J. Nicolson (A., Ph., M.), I. L. Oluwole (A.), J. Paterson (A., Ph.), J. W. Patterson (M., Path.), N. B. Peacock (M.), G. Pearson (M.), B. J. Peters (M.), J. B. Potter (M.), R. U. Qureshi (A., Ph.), I. M. Robertson (M.), J. J. Robertson (M.), F. W. Sandeman (M., Path.), T. B. Sinclair (Path.), C. L. Somerville (M.), T. Stark (A., Ph.), J. Stewart (A., Ph.), A. S. Strachan (M.), J. T. Taylor (A.), J. J. Treanor (M., Path.), J. C. Vaughan (M.), A. R. Waddell (A., Ph.), J. L. Walker (M., Path.), W. A. Walker (A., Ph.), H. D. Wallace (M.), H. Wands (A., Ph.), R. Wiggins (M.), G. M. Wishart (M.), B. Young (A., Ph.), Annetta G. T. Anderson (Path.), Ellen D. Anderson (A., Ph.), Mabel N. Blake (M., Path.), Grace Chatterton (M.), Margharita M. Couper (M.), Grace A. Fleming (M.), Margaret O. R. Gallagher (Path.), Mary B. Gillespie (Path.), Jane E. Hanson (M.), Janet W. Hepburn (M.), Mary R. Knight, M.A. (M.), Elizabeth C. Loudoun (M.), Mary J. Macdonald (M.), Isabella Q. M'Fadzean (M.), Margaret T. M'George (M.), May E. MacVey (Path.), Maud E. D. Mackinnon (A.), Margaret G. M'Vey (M.),

Florence F. M. Milne (A., Ph.), Mercedes M. Morton (Path.), Elizabeth P. Y. Paterson (M.), Vida J. Perry (A., Ph.), Margaret I. Prangnell (A., Ph.), Margaret N. Robertson (Ph.), Agnes P. Routledge (M.), Marjory Mary Scanlan (A., Ph.), Katherine Scott (A., Ph.), Margaret M. C. Steedman (M.), Dorothea H. Suttie (M.), Lydia I. H. Turrance (M.).

The following have passed in Medical Jurisprudence and Public Health of the fourth professional examination (New Medical Ordinance):

J. W. W. Baillie, J. E. Bannen, *W. M. Cameron, R. Cunningham, D. Heard, F. W. Hebbethwaite, G. M. Hetherington, H. F. Hollis, J. R. R. Holmes, *J. N. Jamieson, K. M. Alpine, N. MacKillop, *J. M. Mackintosh, H. Robertson, H. B. Sergeant, A. W. Smith, J. T. Wylie, Janet M. Alexander, Winifred J. Crawford, Margaret H. Glen, Alice J. Marshall, May I. T. Reid, Marion Watson, *Mary MacL. Weir.

The following have passed in Medical Jurisprudence and Public Health of the third professional examination (Old Medical Ordinance):

A. G. Brand, J. MacD. Clark, W. H. Gordon, E. G. S. Hall, T. J. Honeyman, *A. B. M'A. Lang, A. D. C. McGowan, A. B. Stich, J. A. White.

* Passed with distinction in one or more subjects.

Note.—Students under the Old Medical Ordinance who have not previously passed in Pathology will note that at this time in Medical Jurisprudence is conditional on their also undergoing the present examination in Pathology.

UNIVERSITY OF DUBLIN.

The following candidates have been approved at the examinations indicated:

INTERMEDIATE M.B.—*Part I, Anatomy and Physiology*: A. J. Vorster, R. Bosnekov, C. D. Brink, J. J. G. de Kook, W. R. Burns, Olive G. Blackham, H. B. Van der Merwe, W. B. Briggs, I. Widoger. *Part II, Applied Anatomy and Applied Physiology*: *H. L. Parker, *V. M. Syngé, *C. L. Wilson, I. Albertyn, P. J. Molony, R. M. D. Devereux, Mary C. Sheppard, J. C. Fouché, W. L. Young, *W. P. Elford, *W. V. Pellissier, W. Sweetnam, E. E. Rollins, *K. Greer, *T. H. R. McKiernan, P. H. S. Smith, T. B. H. Tabuteau, *E. J. Lydon, *W. A. Shannon, P. A. Dornier, L. J. Nugent, W. F. McConnell, T. S. McDonald, J. G. Bird, Ethel M. Luce, E. S. E. Mack, W. A. W. Cullen, *T. M. Bentley, J. M. Hill, D. McElwee, Olive G. Blackham, J. B. McGrannahan, P. J. Swanepoel.

* Passed on high marks. † Equal.

FINAL M.B.—*Part I, Materia Medica, Pathology, Medical Jurisprudence, and Hygiene*: *P. Rock, *B. W. Nesbitt, J. R. Brennan, H. Brill, W. J. McClintock, S. V. Furlong, H. Banks, A. L. Albertyn, A. I. Steyn, C. P. Chambers, W. P. Lufbbe, C. Weir, S. A. Clark, T. E. Hill, F. W. P. Sullivan (Materia Medica and Pathology), Michael C. Dippenaar (Pathology completing examination), Millicent Hamilton-Johnstone (Materia Medica, Medical Jurisprudence, and Hygiene completing examination), H. H. Molloy (Materia Medica completing examination). *Part II, Surgery*: J. W. Bigger, T. Lane, C. L. McDonagh, L. Blumberg, Millicent Hamilton-Johnstone, M. McG. Russell, Eileen G. Gwynn, F. J. Murphy. *Medicine*: J. W. Bigger, R. C. B. Ramsay, G. W. Doran, J. T. Westby, Millicent Hamilton-Johnstone, Eileen G. Gwynn, R. Gordon. *Midwifery*: Millicent Hamilton-Johnstone, J. G. Bird, F. Healy, J. T. Westby, S. V. Furlong, H. S. Campion.

D.P.H.—*Part I, Bacteriology, Pathology, Chemistry, Physics, and Meteorology*: B. D. Crichton. *Part II, Sanitary Engineering, Vital Statistics, Public Health, Hygiene, and Epidemiology*: J. R. D. Holtby, Marjorie Chapman, Florence Colquhoun.

* High marks.

QUEEN'S UNIVERSITY OF BELFAST.

The following degrees and diplomas were conferred at the spring graduation ceremony:

M.D.—S. H. Davison, F. C. Mann.
M.B., B.Ch., AND B.A.O.—*Eileen M. Bell, D. Corry, *J. Cullenan, C. F. Davey, S. J. W. Donald, J. E. Finlay, Mary E. Henry, Mary M. Keirna, J. M. McCormack, *J. C. McMillan, Joseph R. M. Mackenzie, J. F. W. Meenan, W. N. Montgomery, R. L. Sinclair.
D.P.H.—*Dr. A. M. Elliott, *Dr. P. J. Gaffikin, Dr. H. M. Jackson, Dr. R. J. Morgan.

* Second-class honours. † In absentia.

THE Association of Infant Welfare and Maternity Centres desires to make it known that it has not authorized the use of its name in connexion with the child life and welfare exhibition to be held in London in June.

THE American Gynecological Society will hold its forty first annual meeting at Washington on May 9th and the following days. The principal subjects for discussion are syphilis, cancer of the uterus, and painless labour.

THE National Union of Trained Nurses has addressed to the President of the Board of Trade a memorial begging that an inquiry should be instituted regarding the articles and memorandum of association of the proposed college of nursing, on the ground that it would be against the best interests of the nursing profession that the scheme in its entirety and with its present articles should be permitted to proceed. It is asked that the scheme should be examined by a competent body of professional experts, including representatives of the General Medical Council and of the British Medical Association, as well as of societies of trained nurses.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

PERPLEXED inquires as to the deductions to be made in respect of his motor car.

* * All running expenses, petrol, tyres, repairs, etc., also such recurring expenses as insurance, licences, etc., are deductible as ordinary locomotion expenses. No allowance is due for depreciation, whether caused by wear and tear or otherwise; but the actual net cost of renewal or replacement is admitted to be a proper subject for deduction in calculating the profits for the year in which that expense was actually incurred. In the case put by our correspondent—namely, the sale of a car for £100 owing to depreciation from wear and tear and the purchase for £375 of a new car—£275 would be a correct deduction. It should be borne in mind that the deduction is not to be made from the average profit but in arriving at the profits entering into the average.

W. M. M. J. inquires what income tax would be payable on an income made up as follows:

	£	s.	d.
R.A.M.C. pay (gross)	359 16 0
Professional earnings from practice abroad...	85 0 0
Unearned income (net)	122 0 0

* * Assuming that our correspondent would not be residing in this country if he were not in the military service, we think that the £85 will probably be regarded as exempt from taxation. The sum of £122 is presumably the net amount after tax at 3s. in the £ has been deducted, in which case the gross amount would be about £143 10s., and our correspondent's gross taxable income would therefore be £360 + £143 = £503. It is unfortunate that this exceeds £500, inasmuch as the lower scale of abatements applies and the higher scale of rates of tax. The unearned income being taxed, the only tax payable direct is on the pay, namely, £360 less £100 (= £260) at 1s. 9d., that is, £23 8s.

LETTERS, NOTES, ETC.

"METRIC PRESCRIBING."

DR. W. W. HARDWICKE (London, S.W.) writes: In my letter in the issue of April 1st, the sign for "centimilligram," *cmg.*, was, by an error of the printer, converted into "cubic milligram" by the insertion of a stop after the c. The metric equivalent for 1 grain, shown as 0.65, should have been .065. I regret that, when correcting the proof, the errors escaped my notice.

SALVARSAN.

MR. JOHN WEBSTER, F.I.C. (St. Mary's Hospital, W.), writes: In the paper contributed to the BRITISH MEDICAL JOURNAL of April 1st by Dr. Wilcox and myself, the formula of salvarsan has by an oversight been given as $C_{12}H_{12}O_2N_2As_2(HCl)_2$, instead of

This latter formula gives an arsenic content of 31.6 per cent. (= As_2O_3 41.7 per cent.), and not 34 per cent. (= As_2O_3 44.9 per cent.) as stated in the paper.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

Remarks

ON

"COLDS" AND THE INFLUENCE OF THE
ATMOSPHERE ON THE NASAL
MUCOUS MEMBRANE.

BY LEONARD HILL, M.B., F.R.S.,

DIRECTOR OF THE DEPARTMENT OF PHYSIOLOGY, MEDICAL
RESEARCH COMMITTEE.

EPIDEMICS of "colds" are most common when the humidity of the atmosphere is great, and the temperature variable but on the whole cool—when the weather is raw with thawing snow, or strong winds blow charged with cold rain, and the ground is wet and cold. Cold dry weather and strong drying winds do not favour these epidemics. Men living open-air lives are free from "cold" whatever exposure to extremes of weather they undergo—for example, sailors on long voyages, arctic travellers, troops at the front. The health of the navy at sea in war is better than in peace; the sailors are far less exposed to temptation to over-indulge, and to infections from the civilian population in port. Shackleton in his antarctic expedition recorded a single outbreak of "cold" after the opening of a bale of clothes packed in London. Men taken from shop or office, turned into soldiers, and put under canvas, escape the "colds" from which they suffered in civil life. When children after the holidays return to school, epidemics of "cold" usually begin to run through the community. In the holidays they may paddle all day in the sea, bare-legged, exposed to far greater cooling than at school, but they do not suffer from "colds" then. The "colds" begin when the weather confines them in shut-up and artificially warmed schoolrooms and places of assembly. The latter are the happy hunting ground of the infecting microbe, which does its work while the little innocents raise their voice in the morning hymn. A certain propinquity is required in order that the infected saliva spray sneezed, coughed, or spoken out, may be carried from a "carrier" to another victim. Out of doors folk do not crowd so closely, and the ventilation is very much greater; the saliva spray is blown away, and the infection cannot be massive, as it may be indoors or in railway carriages, where the atmosphere is comparatively still.

But this is not the whole story. Why do certain weather conditions cause epidemics to sweep through the communities of our cities? Why are those who live an outdoor life relatively immune—hardened—both to weather conditions and infection? What is the nature of the hardening process set up by exposure to weather and cold baths? In spite of the popular opinion to the contrary, it is clear that exposure, even to extremes of cold, by itself does not occasion "colds" or pneumonia. Shipwrecked folk, exposed almost to that point of chilling which stops the vital functions, do not after rescue suffer from coryza or pneumonia; neither do the troops exposed to the severest hardship in the waterlogged trenches. "Trench foot" seems to be the combined result of local chilling and waterlogging of the skin. Dry cold can be withstood very well, or prolonged exposure to salt sea water. In the case of trench foot it is the osmotic conditions of the tissues which are upset by the soaking of rain water into the chilled skin, while the tissues are poisoned by the products of bacteria which multiply within the confinement of the boot and stocking. A local damage thus results from prolonged and extreme exposure to wet and cold. On the other hand, the troops so exposed are singularly free from pneumonia, "colds," and epidemics of the influenza type.

The domestic animals—cow, pig, horse—with a relatively scanty covering of fur, not only withstand, but thrive on, continued exposure to wintry weather in the fields, or in cold, draughty byres. Stock raisers know that artificial means of heating cannot be used with success. Fowls will not thrive in artificially heated pens. The incubator chick is not so robust as the one hatched by the hen. So is it with the child coddled in heated rooms at home and at school.

Acute rhinitis or coryza, the common cold, may be caused by bacterial infection; by dust—for example,

cycling in the dust of motor cars; by a chemical irritant—for example, sulphurous acid from furnaces; the poison gas cloud of chlorine suffocates by causing the outflow of fluid in the air passages; by the pollen of certain grasses. There is also a class of people who suffer from a nervous derangement of the nasal membrane, from vasomotor rhinitis or paroxysmal rhinorrhoea as it is called. The nasal reflexes of such people are unduly excitable—hyperaemic patches may sometimes be seen on their nasal mucous membrane. Sudden changes of atmosphere—a draught—may provoke in these an acute paroxysm. These people are pathological, hypersensitive, but it is probable that their noses have a great influence on the habits of the nation. The laity do not distinguish causes. It is manifest that some people are acutely affected by draughts, and therefore draught becomes popularly considered the chief cause of "colds." Nursery and family tradition rules habits, and tradition is usually at least half a century behind science. Science may beat against the door but tradition holds it fast.

It is generally believed that more nasal catarrhs are contracted through cold feet than in any other way, and yet soldiers whose feet are chilled to the local death of tissues do not have "colds" in the head therefrom. Under what conditions does chilling of the feet inflict punishment on the nasal membrane? and how is it influenced by conditions of humidity and draught? These are questions which are well worthy of inquiry, but little attention do they seem to have received so far.

F. F. Muecke and the writer¹ drew attention nearly three years ago to the appearance of the nasal mucous membrane when the subject is exposed first to outdoor conditions, and secondly to those conditions of heating and ventilation which are not uncommon in rooms. Out of doors the wind moves at a much greater velocity at head than at foot level, owing to friction of the moving air against the ground; the ground, too, is warmed by the sun. As a rule, then, excepting such unpleasant conditions as pertain to thawing snow, the head is cooled at a greater rate than the feet. Cool breezes blowing round the head, the radiant heat of the sun, and a warm ground to stand on, are the ideal outdoor conditions. The healthy mucous membrane of the nose, examined by aid of a speculum, under these conditions appears pale and taut. If touched with a probe it does not pit, and there is no thick secretion upon it. Indoors, in those conditions which are unfortunately only too common, when the feet are chilled by draught blowing over a cold floor, and the head is immersed in warm stagnant air, the nasal membrane appears swollen, congested, and covered with thick secretion. A probe pushed into the swollen membrane forms a pit, showing how boggy it is, and the airway is so diminished that a person with a spur of bone or any kind of obstruction cannot breathe through the affected nostril. Warming the feet at a fire at once relieves the congestion and does away with the obstruction, so that the airway again becomes free. It is this congestion and swelling of the nasal membrane, and no doubt also of that of the air sinuses opening into the nose, which largely causes the feelings of stuffiness in the head and headache felt in crowded, overheated places of assembly. This headache is generally, but erroneously, attributed to the absorption of chemical poisons supposed to be present in the stuffy air.

In the chamber of the House of Commons the ventilating current is driven up through the floor in such a way as to cool the members' feet, while their heads are exposed to more stagnant air. Cold feet and stuffy heads result—just the wrong conditions for legislators. The thermometer, it is true, shows a uniform temperature of 63° F.; but the katathermometer,² an instrument invented by the writer for measuring rate of cooling at body temperature, shows that the members' feet are cooled at a rate which is 50 per cent. or more greater than the cooling of their heads. The writer has his left nostril obstructed by a deflected septum. Sitting on a bench in the House of Commons he found his left nostril became completely obstructed in the course of a very few minutes. During the inquiry of the Ventilation Committee of the House of Commons he was allowed to make experimental alterations in the system of the ventilation in one part of the chamber; closing up the floor inlets there, he introduced air at the Gallery level. Under these conditions his feet were warm, his head agreeably cooled by a slight and grateful movement of the air, and his nasal airway unobstructed. Changing to and fro, from the part ventilated on the old system to that

ventilated by the new, his left nasal airway each time became obstructed by the old, opened by the new.

An easy and striking way of demonstrating the change in the nose is to install in a small shut-up room a gas fire fitted with no flue, so that all the heated air escapes into the room and rises into the upper part. Then with the aid of mirror and speculum examine the noses of, say, half a dozen subjects who first have been in the open air, secondly have been for some minutes in the room. A properly flued gas fire, which warms the floor and feet by radiant energy, will of course put the nose again into good condition. Toasting the feet at such a fire immediately relieves the nasal congestion and opens the airway.

Cold feet *per se* do not have this effect on the nose. The writer has observed in himself, when walking in melting snow or cycling in a cold wind along snow-covered roads, that his feet may be most uncomfortably cold, but his left nasal airway is wide open. His head, under these outdoor conditions, blown upon by the cold wind, has been as cold as his feet. It is the indoor conditions of cold draughty floor and warm stagnant air round the head which produce the congestion, swelling, etc., of the nose. These are conditions entirely opposed to the natural conditions out of doors.

A leg put into warm water responds by local vaso-dilatation; a leg put into cold water becomes pale with constriction and may even shiver, while the rest of the body is warm and keeps quiet. Out of doors the cold air is inhaled, and the naked face more than any part feels the cooling effect of the wind. The nose then is made taut—constricted—even though the feet be cold. Indoors, when the feet on a draughty cold floor are chilled and constricted, and the head is in a bath of warm stagnant air, the nose becomes congested, both by the local effect of the warm air and also by the blood, which is determined to all dilated parts from the cold-constricted feet. Warming the feet, therefore, at once lessens the congestion of the nose and opens the airway.

The ideal method of warming and ventilating rooms would give us abundant radiant heat, a warm floor, and agreeable movement of cool air. Such conditions are found in one-storied foundries where the roof openings are designed of ample size. The health of men engaged in foundries is very good. The Roman hypocaust gave a warm floor, and with unglazed openings must have secured warm feet and cool heads.

Open fires, and properly flued modern gas fires, give us radiant heat, and a warm floor within the range of this heat. We can toast the feet at these, and much of the hot air goes up the chimney. The so-called radiators, gas or steam, and artificial lights, together with the heat and moisture from the bodies of people, make warm and humid the upper strata of rooms, and afford the conditions bad for the nose.

Suppose the nasal membrane has become swollen, congested, and covered with thick secretion in these bad conditions, and the subjects go outside again into the cold air; then the membrane at once becomes pale, owing to vaso-constriction, but for some little time it remains swollen and boggy, pitting on the touch of the probe. I believe that these conditions of the nasal membrane have a great deal to do with the "catching of colds." In crowded rooms infection takes place from mucous spray, sneezed, coughed, or spluttered out in speaking. The inhaled bacteria will be caught by the swollen mucous membrane covered with thick secretion. In cold outside air not only is the membrane kept taut, but the flow of blood through it is rapid, for the inhaled air has to be warmed up and moisture rapidly evaporated from the membrane so as to saturate this air at body temperature. Thus more lymph comes out into the membrane from the blood vessels, and this contains the immunizing substances. The offensive bacteria are washed away or destroyed and thus kept out. On the other hand, in the condition where the membrane is covered with thick secretion, congested and boggy, there is a medium more suitable for the bacteria to settle and grow on, for it is boggy and stagnant, not flooded with fresh lymph, particularly when vaso-constriction takes place on passing from an over-hot, moist atmosphere into the wintry outside air.

The washing away of bacteria by the outflow of secretion must be one of the most important methods of defence. In the alimentary canal poisonous concentrations of substances—for example, sugar—are diluted and kept away from the living membrane by the secretion of

mucus. In the respiratory tract fluid is poured out to dilute and wash away a chemical irritant such as chlorine. Now the rate of evaporation from the nasal membrane must be of first importance in promoting the outflow of lymph through it, and the factors which determine this are worth considering.

At 30° F. air saturated with water vapour holds 1.9 grains per cubic foot. At body temperature the saturated air holds no less than 19 grains. Exhaled air is warmed up to, and saturated at, body temperature, and a cubic foot of air is breathed by a resting man in about four minutes. Thus the nasal membrane, if it saturate air inhaled at 30° F., will evaporate $19 - 1.9 = 17.1$ grains of water (about 1 c.cm.) every four minutes. If the man is taking exercise the nose will evaporate this amount every minute, or even every half-minute, owing to the increased respiration. This means that two or three ounces may be evaporated from the nasal membrane in the course of an hour's exercise on a wintry day.

The argument so far has taken it for granted that the nose does it all—it may not; when exercise is taken other parts of the airway may share in the evaporation and beneficent outpouring of lymph.

Now let us turn to the atmosphere in spinning mills or weaving sheds saturated, say, at 75° F. Such air holds 9.4 grains per cubic foot, and to saturate it the nose will only evaporate 9.6 grains a minute—a little more than half the above amount of water. I will set out the figures for the whole range of temperatures from 30° to 90° F.

TABLE I.—Amount of Water in Air Saturated at Various Temperatures.

Air saturated at 30° F. holds 1.9 gr. per cub. ft.				
"	"	40° F.	"	2.8
"	"	50° F.	"	4.1
"	"	60° F.	"	5.7
"	"	70° F.	"	8.0
"	"	80° F.	"	10.9
"	"	90° F.	"	14.8
Air saturated at body temperature holds 19.0 gr. per cub. ft.				

It is of course the rapid increase in the containing power of the air, as the temperature rises, which enables us to keep our bodies cool, by sweating, in saturated atmospheres when the temperature is even 80° to 90° F. There is a big difference between 10.9 at 80° and 19 at body temperature, and on this the tolerance of humid tropical conditions depends.

Under ordinary indoor conditions, with a temperature of about 60° dry and 55° wet bulb, there will be about 4 grains of water vapour in each cubic foot of air; at 30° F. there is 1.9 grains. We see, then, that the difference between the evaporation from the nose on passing from wintry air to the indoor conditions is about 12 per cent.—17 grains per minute in the one case, 15 in the other. In the spinning mill at 75° F. (saturated) the evaporation is about 42 per cent. less than out of doors on the wintry day.

The demands made on the circulatory and evaporative mechanisms of the nose are, then, great on changing suddenly from this warm atmosphere to the cold outdoor conditions. A much greater supply of blood is required to keep the nose warm, and a greater passage of lymph to keep up the evaporation in the cold outdoor air. No wonder sudden changes of conditions from over-hot, humid rooms to raw, wintry weather strain the vaso-motor and secretory mechanisms and help to cause "colds." No wonder, when "colds" are upon us, that it is advisable to keep to one uniform temperature and stay indoors—as we cannot very well stay out. These sudden changes are quite unnatural to the wild animal, but the dog shares them with civilized man. The dog, however, is another story—he is not, as a rule, crowded with his fellows indoors; he hardens himself by wearing no clothes, is less infected and more immune, like the man whose work is in the open air. Our feeling of comfort depends very closely on the effect of atmospheric conditions on our skin and nose. It is probable that we are sensitive to any change in the rate of evaporation from the nasal membrane. Humid air must check evaporation until the nasal membrane has warmed up the air and so made it capable of holding more moisture. This is particularly so in the case of mist or fog; the cold particles of water must first be evaporated before any evaporation from the membrane can take place. The cold particles also chill the nerve endings in the cold spots of the skin, while the moisture

adsorbed by the clothes lessens their heat-retaining properties. Hence our discomfort and the chilly effect of a fog. Relatively dry air, on the other hand, does not check evaporation or cool the nerve endings in the same uncomfortable way.

Miserable raw wet weather, wind-driven rain or sleet, impels us indoors, and makes us shut up windows and crowd in heated rooms. Exposure to infection is thus made greater while the inability to take open-air exercise in such weather may diminish the vigour of health, which depends so intimately on the rate of metabolism and the influence of exercise on the digestive organs. There is evidence that the prevalence of cases of cerebro-spinal fever is associated with cold, wet weather and the crowding of soldiers in the humid, confined atmosphere of huts and billets.¹ Under canvas the ventilation is far freer, and the atmospheric conditions favour evaporation from the nasal membrane and prevent its congestion. In stove-heated huts crowded with men, with damp clothes steaming, the temperature and humidity rise to heights which are quite impossible under canvas.

The effect of the cool outdoor air in promoting the flow of blood through the nasal membrane is no less noteworthy than that of evaporation. A greater blood flow is not only required to maintain the evaporation, but to keep the membrane at body temperature.

The specific heat of dry air at constant pressure, and 20° C. is 0.24—that is to say, 1 gram of air takes 0.24 small calorie to warm it up 1° C.; 1 gram of air has a volume of 778 c.cm. measured at normal pressure and temperature. To warm to body temperature each litre of air breathed, then, approximately 0.3 small calorie is required, that is for each degree centigrade through which it is warmed.

If the atmosphere is at freezing point, 11 small calories will be required for each litre breathed—say 77 small calories a minute for the resting man. At 65° F. this amount will become 38; at 75° F. only 26. At ordinary room temperature, then, only half the heat will be required to warm the air breathed as at freezing temperature.

Taking exercise out of doors on a cold winter day and breathing 40 litres per minute, a man may lose 4 to 5 large calories of heat per minute in warming the air he breathes, against 0.38 sitting in a room at 65° F. We see, then, how much more blood is required to keep the nose warm in the outdoor conditions.

Herein lies one explanation of the benefit of open-air exercise, sleeping in the open air, etc. The greater circulation through, and the greater evaporation from, the nose together increase its immunity to infection.

To test the views put forward above as to the circulation in, and evaporation from, the nasal membrane we have carried out some observations on the temperature of the nose and the fluid secreted by it, first indoors and then outdoors exposed to cold winds.

If the temperature within the nose is maintained almost at body temperature not only indoors but when the face is blown upon and cooled by strong wintry winds and cold air is breathed, it is clear that much more blood must then flow through the nasal membrane per minute. Now this is what is found to be the case in observations carried out on different days and on four subjects. The temperature was recorded by inserting a delicate flat-bulbed thermometer far up, so that the bulb lay below the inferior turbinate.

TABLE II. —Temperature of Inside of Nose under Various Conditions.

Subject.	Temperature within Nose.		Temp. on Roof.	Temp. Indoors.

B. M. ...	35.5°	35.25°	1	"

* Strong cool wind. † Cold wind. ‡ Snowstorm, cold wind.

We conclude, then, that when out of doors a man has much more arterial blood flow through his nasal membrane per diem than when indoors in heated atmospheres.

It is a common observation that exposure to cold wind makes the eyes water and the nose run—signs of that flood of fluid which is poured out to keep exposed surfaces wet and warm.

The secretion from the nose was measured in a way which gives a rough but none the less trustworthy indication. We passed a weighed probe covered with absorbent cotton-wool up the nose, left it there for three minutes, and then weighed again. A number of such weighed probes were first made ready; then a probe was passed up the nose to mop up whatever secretion might be there; after this we waited three minutes and then the observation went forward, first for three minutes indoors, and then for three minutes outdoors on a roof exposed to the wind. The results obtained were as follows:

TABLE III. —Amount of Nasal Secretion under Various Conditions.

Subject.	Secretion taken up by Probe in Three Minutes.		Temperature Indoors.	Temperature Outdoors on Roof.
	Indoors.	Outdoors on Roof.		
P. ...	0.119 grm.	0.269 grm.	16.2°	2.3; snow, cold wind.
W. ...	0.065 "	0.186 "	"	" "
L. H. ...	0.173 "	0.253 "	15.9°	10.1°; cold wind.
B. M. ...	0.063 "	0.208 "	"	" "
B. M. ...	0.10 "	0.152 "	16.3°	Snowstorm, cold wind.
L. H. ...	0.067 "	0.123 "	"	" "
B. M., right nostril	0.135 "	0.173 "	15.2°	Snowing, cold wind.
B. M., left nostril	0.029 "	0.286 "	"	" "

The last pair of observations on B. M. are of interest because the right tear duct was blocked and the right side of the nose "stuffed up" as the after-result of a "cold." We only put stress on the general sense of the figures, not on the actual amounts given as representing the secretion caught by the probe. We believe the increase out of doors was generally under-valued; in the case of W., for example, when exposed to cold wind, the secretion ran down the probe and dropped off its end—the wool had become too wet to absorb it. The internal structure of the nose is so arranged that the secretion mostly runs backwards into the pharynx when the head is held in the normal position, and it is only the anterior part which furnishes the secretion which runs to the tip of the nose and enforces the use of the handkerchief.

The above figures, then, confirm the theoretical views which have been set forward, and before laying down the pen we would point out that the conditions which we have discussed in regard to the nose no less pertain to wounds; the flow of lymph through, and evaporation from, the wound counteracts infection and hastens healing. A suitable dressing and ventilation are required to ensure the adequacy of lymph flow. The dressing must prevent premature closing of the wound by a scab. Sir Almroth Wright's salt treatment by osmotic force pulls out lymph with its immunizing properties, and the outflow washes away infecting bacteria. Now that the open-air treatment of wounds is extolled, the surgeon's attention may perhaps be directed to the problems of evaporation from, temperature of, and blood flow through wounds, in so far as these may be influenced, not only by dressing, but by the relative dryness, temperature, and movement of the atmosphere.

The writer is indebted to Dr. Benjamin Moore, F.R.S., for help in carrying out the measurements.

"THE SOLDIER'S HEART" AND ITS RELATION TO THYROIDISM.

BY

SIR JAMES BARR, M.D., LL.D.

WHEN the Editor of the *BRITISH MEDICAL JOURNAL* accepted my offer to write on this subject I felt that it required some temerity to enter an arena where so many doughty champions had recently striven for mastery, and not one of them, in his own opinion, knocked out of the ring. I read all the letters and articles in the *JOURNAL* on their publication, and imbibed as little as I thought necessary. Unfortunately this has involved a second reading (a form of amusement which I do not much appreciate), in order to find out whether all the writers were dealing or intended to deal with the same cardiac affection, or whether each writer had a particular disease of his own to describe. However hazy the ideas of some of them may have been, I came to the conclusion that they all intended to deal with the old "irritable heart."

The contributions of Dr. Alexander Morison, and his references to the soldier's heart as part of a general state of nervous exhaustion are excellent so far as they go, but he does not carry us far enough, and is apt to leave us in that neurasthenic land of the destitute. On the other hand, I should like to employ to Sir James Mackenzie's article on "The Soldier's Heart" the language which he used to Sir James Kingston Fowler. It is "vague, immature, insisting on the immaterial, and neglecting entirely the essential." On causation he is not the only writer who flies to that resort for the destitute—microbes and their toxins—to explain all the ills to which flesh is heir. It is to be noted that there is not a single bacteriologist on whose evidence one would condemn the most harmless staphylococcus in support of this view; the reason, perhaps, is that bacteriologists have had a scientific training, which makes them less prone to jump to a conclusion than the clinician, who becomes very positive on the subjects which he least understands. The modern heart specialist often does not even consider an elementary knowledge of physics essential for his speciality.

It is well recognized that in diphtheria, in typhoid fever, and, in fact, in any case of prolonged high temperature, cloudy swelling of the myocardium, as well as of the liver cells, may occur. In rheumatic fever the myocardium is often involved, and this can readily be recognized two or three days before the appearance of any murmur by the delay in the transmission of the pulse wave. In the case of the irritable heart the sounds are short and sharp even when there is a murmur, and there is no delay in the pulse wave—the interval between the mitral first sound and the pulse at the wrist is barely appreciable. Influenza often gets the credit of causing heart mischief, but it usually seems to me more of the nature of a neurosis accompanied by pain than a myocardial infection. Moreover, the alcohol which is too frequently and too freely administered may have some share in the causation, especially in those cases in which there is dilatation. The heart's action is quickened, the sounds short and clear, and in these respects it differs from the myocardial condition in diphtheria.

Like the civilian the soldier is liable to all the varieties of heart disease, but what seems to me strange is that although almost any kind of heart, according to Sir James Mackenzie, is good enough for a recruit, a large number of recruits get bowled over with some functional disease of the heart even before they reach the trenches. So bad does this irritable heart seem to be for those who have passed the recruiting stage that Major Bradshaw goes so far as to say that they should be invalided out of the service. If this were an established order it would be a simple matter for any one who has no stomach for fighting to get released.

In all cases of irritable heart which I have seen there has been some enlargement of the two lateral lobes of the thyroid gland with increased function. I have also found that gland enlarged in a considerable number of cases of frost-bite, or to be fashionable I suppose I should say "trench feet"; and I hope to show some relation in the causation of these affections. I am well aware that the enlargement is not always very apparent. The thyroid gland is best examined with the patient lying on his back

with his shoulders and head supported on a gentle incline from the waist upwards; the two lateral lobes can then be easily felt internal to and behind the sterno-mastoid muscles. If the patient raises his head, so as to make the muscles and fascia tense, the whole gland disappears as if by magic. There is usually some throbbing to be felt in the carotids, and possibly also in the arteries supplying the thyroid.

HYPERTHYROIDISM.

In a paper on the functions of the thyroid, the supra-renal, and pituitary glands,¹ I said:

Exophthalmic goitre is now, I think, almost universally acknowledged to be due to excess of function of the thyroid gland. In the case of marked exophthalmos a large pulsating thyroid, tachycardia, general nervous trepidation—the patient in an apparent state of fright, emaciation, a moist skin with consequent lessened electric resistance—any fool can tell what is the matter; but there are an enormous number of cases of hyperthyroidism in which there is no exophthalmos, no apparent enlargement of the thyroid, and no pronounced nervous symptoms. However, in these cases an intelligent observer will readily detect a tendency to emotional and vasomotor disturbance, a warm moist skin, warm extremities, active capillary circulation, rather high venous pressure, rapid action of the heart and the rate easily increased by any mental excitement, the knee-jerks and all the deep reflexes increased, and slight muscular tremor may be appreciable. In all degrees of hyperthyroidism the urine may contain a slight amount of albumin, especially after getting up; this corresponds to the so-called albuminuria of adolescence, and is associated with deficient vasomotor tone and a lessened amount of fixed lime in the blood. The free lime in the blood may or may not be increased, but there is always an excessive excretion, except when there is a very small intake. In cases of hyperthyroidism there is a state of unstable equilibrium; the individual is sharp, alert, even vivacious, but easily exhausted both mentally and physically, and so incapable of sustained effort.

The causes of the thyroid taking on this over-action, beyond the necessities of the system, are still rather obscure. This over-action cannot have any necessary connexion with the condition of the water in goitrous districts, because the large fibro-cystic masses are associated with lessened function of the gland, though of course in many such cases there may have been a primary excess of function, and we know that many cases of exophthalmic goitre end in myxoedema. However this may be, many are of opinion that the cause is water-borne, and can be destroyed by boiling, but the proof adduced in support of this contention is far from conclusive.

We do know that the active principle of the gland contains iodine, and that excess of function of the thyroid is always associated with excess of iodine in the gland. I have seen two cases of exophthalmic goitre, including well-marked exophthalmos, produced by a prolonged use of tincture of iodine, and both cases were rapidly cured by stopping the iodine and placing them on a calcium mixture. There may be sources of iodine difficult to trace in individual cases, but in every case one should keep his faculties of observation alert, try to find out the cause, and remove it. In every case the urine should be examined for iodine, though it is not often found unless the patient has been taking an iodide. Many medical men will tell you that they prescribe iodine and thyroid in such cases with advantage, but upon what grounds I cannot say, unless it be a hair of the dog that bit you, or the homoeopathic doctrine that like cures like; in that case, the more infinitesimal the dose the better. It may, however, most likely be that in such men's minds there is a confusion between over-action and under-action, exophthalmic and fibro-cystic goitre.

In the textbook etiology of hyperthyroidism the common cause, the female sex, is absent, but some men are as emotional as women. In the latter the thyroid gland is usually active about the menstrual period and during the early months of pregnancy. In men the supra-renal gland is ordinarily the more active, but in neurasthenia and in some febrile affections, such as diphtheria and pneumonia, the adrenalin function may be inadequate, and thus the controlling influence over the vasomotor system is lessened. In war other assignable causes are in force, such as mental and physical strain, worry, anxiety, and fear, vicissitudes of climate and temperature, want of sufficient rest and sleep, too much meat and not sufficient milk and cheese, and too much tobacco.

No wonder that under such conditions which go to make up the life of the soldier we should get great vascular disturbance and increased function of the thyroid gland. In great dread of any impending catastrophe the heart makes its presence felt by thumping against the chest wall. Anticipation is worse than action. When it was pointed out to the Irishman that, from his description of his wound, the bullet must have passed straight through his heart, he replied, "In faith my heart was in my mouth at the time."

The intensity of the symptoms varies very much, according to the excess of function rather than the mere size of the gland. In the cases of "the soldier's heart" the subjective symptoms are referable to that organ, but any careful observer should notice many other indications of increased thyroidism. The cardiac beats in these cases are frequent, usually from 80 to 120 in the minute, and the number is greatly increased by any emotional disturbance. This quickened action is accompanied by a certain amount of palpitation.

The eyes are, as a rule, not very prominent, but the sclerotics are frequently more than usually visible. The skin is warm and moist, except in cold weather, but even when the hands are cold the head is warm and the face often flushed. The tongue is rather tremulous and often indented at the edges by the teeth, there is usually some muscular tremor, a certain amount of trepidation and abruptness in manner. There is great dissipation of heat, and consequently when the body is much exposed to cold and wet the extremities become very cold and the fingers often dead, especially the distal halves. When the blood pressure is low the fingers and hands may get livid or purple and somewhat swollen from the slow capillary circulation, but this can be remedied by hanging the hands down and exercising them so as to increase the velocity of the blood in the capillaries. The toes may be a little livid when the patient is lying down, but not when he is standing up, as in the latter position the velocity of the capillary circulation in the feet may be at least quadrupled—always provided that the arterioles have not been so contracted by the cold as to shut off the capillaries. This condition of the circulation renders these men particularly liable to frost-bite, or the modern trench feet.

There is another strongly predisposing cause, a deficiency of lime salts in the circulation. This arises from insufficient intake and the excessive output which accompanies hyperthyroidism. The soldier's rations, in my opinion, do not contain a sufficient amount of calcium—the milk is scarce and each man only gets about 2 oz. of cheese daily. Whenever there is severe muscular work there should always be a large intake of lime. In mountain climbing I always increase my own supply. When there is hard work there is no danger in taking too much; a certain proportion is not absorbed, and any excess in the circulation is quickly excreted. In cases of "the soldier's heart" we get, as Dr. Jamieson Hurry would say, a vicious circle; the deficiency of calcium salts in the blood is a contributory cause in the production of hyperthyroidism and frost-bite, and the excessive action of the thyroid leads to great calcium metabolism.

So far as we at present know, the presence of free calcium ions in the blood and tissues is necessary for effective muscular contraction. The calcium ions increase the force of the muscular contraction, but diminish the irritability of the muscle, and, according to Loeb, inhibit the rhythmical contraction of muscle fibres, which he thinks does not depend on lessened excitability, but on some chemical combination of the calcium ions in the muscle which renders its rhythmical contraction more difficult or impossible. Sydney Ringer, in association with Dudley Buxton, showed that the effects of the salts of sodium, potassium, and calcium on skeletal muscles were somewhat different from their effects on the heart. The contractibility of skeletal muscles perfused with normal saline solution lasts longer, but when exhausted there is greater delay in relaxation. The contractions are strengthened and the relaxation delayed by potassium salts. On the other hand, the lime salts accelerated both contraction and relaxation. Personally, I have usually found that patients liable to cramp had a deficiency of lime in their blood, and thus the remainder contraction, so apt to occur in exhausted muscles, is not counteracted by a sufficiency of calcium. I still hold my former opinion that the calcium ions lessen the irritability of the heart muscle, and Blair Bell has shown that when a solution of calcium chloride was injected into the vein of a rabbit the rhythmical contraction continued, the amplitude of the contractions increased, but their frequency diminished, and when a poisonous dose was used the heart finally stopped in systole.

The late Ralph Mines showed how cardiac contraction was due to a difference in electrical potential between the ions within and without the cells.

We have many reasons for believing that the excitation process in muscle can be dissociated from the contractile process, and it seems clear that the electric variation is a direct index of the excitation process, while the contraction is a sequence, usual, but not quite inevitable. Just as in nerve, excitation occurs (but no contraction), so in muscle excitation occurs; if the contractile mechanism is in order excitation is followed by contraction.

In an experiment which I witnessed in his laboratory it was seen that the electric variation preceded the contraction of both the auricle and the ventricle, and, whether the cause or not of the contraction, it began the sequence of events, and, therefore, could not be the result of the contraction. In every case of excessive muscular action there is a great waste of lime salts, hence the necessity of a large intake.

The blood pressure in hyperthyroidism is very variable and merits special consideration. There is lessened peripheral resistance, the viscosity of the blood is diminished owing largely to a deficiency of fixed lime, the arterioles are relaxed, and the capillary circulation is active and free, all of which tends to lower the arterial pressure—at least the diastolic pressure. On the other hand, the capillary and venous pressures rise, the supply of blood to the heart is great, the ventricular cavities are large, and the systolic output great. Therefore, the systolic pressure may be fairly high, but as the arteries are large and the peripheral resistance low, there is a great fall in the pressure gradient, with a relatively low diastolic pressure. This great difference between the systolic and diastolic pressures means an inefficient circulation; it is therefore important that vascular tone should be maintained, and it is for this reason that adrenalin plays an important part in the treatment. When there is a great disparity between the systolic and diastolic pressures, and more especially when the systolic is relatively high, we get longitudinal straining of the large arteries, and marked recoil of the heart. It is this recoil which causes the thumping of the heart against the chest wall which is of frequent occurrence in hyperthyroidism, and is especially marked when a runner comes to a standstill after a strenuous race. In free aortic regurgitation this recoil often shakes the bed on which the patient is lying. It is often noticeable after an extra glass of spirits when the body is in a warm atmosphere. I do not mean that the extra glass, which develops the palpitation, is the only one which works the mischief, but it is the final straw, and the amount of the previous load will depend on the strength of the liquor and the capacity of the individual. This is an early stage in the development of the German beer-drinker's heart, which eventually ends with great hypertrophy and dilatation. "The soldier's heart" seems to be giving as much trouble in Germany as in this country. Dr. Goldscheider, in an interesting address, concludes that "the war had brought into unflattering prominence the ignorance of the medical profession of a group of symptoms with which a very large proportion of the soldiers in the German army were invalided."

The victims of the "soldier's heart" are easily exhausted and get short of breath on slight exertion, but pain in the cardiac region is not a very prominent symptom unless the heart be dilated. When lying in bed the heart gives very little trouble, unless the patient is suddenly startled or quickly assumes the erect posture. These patients are liable to febrile attacks, but that forms no part of the cardiac trouble.

The large class of cases of hyperthyroidism covers much more than "the soldier's heart." When the cardiac phenomena are prominent the diagnosis seems to be fairly obvious, but if the heart does not come into prominence, which it often does not, then the cases are pushed into the neurasthenic class. When one of these patients sometime back from the front is asked what is the matter he blurts out "NEURASTHENIA," and at the same time looks startled. It is then time to point out that there is no object in having neurasthenia at present, as although in civil life the shocks to which he had been subjected would be sufficient to satisfy any jury that he was suffering from traumatic neurasthenia, yet the Workmen's Compensation Act does not apply. There is no railway company to attack, and it is somewhat doubtful whether there will be any pensions for neurasthenia, or even frost-bite. Moreover, a neurasthenic patient should not suffer from a

flushed face, hot head, excitable pulse, and a general appearance of fright.

I recently saw a marked case of hyperthyroidism most unjustifiably dubbed neurasthenia.

A lieutenant, aged 25, joined the army soon after the commencement of the war, very keen and anxious to excel. He had hard work training, and on one occasion fainted at drill. Again in London he fainted in the street, was seen by a doctor, who said that he had a large heart. After this he spent some time in a nursing home under a physician who does not seem to have given any diagnosis except that his heart was not enlarged. He then went for a course of training at Winchester, and finally was sent to France in November, 1915. He had rather strenuous work, and as a bombing officer his duties were chiefly at night; he was seldom in the trenches in the daytime except to see that the bombs were all right. He had no fear of shells or other missiles, but he could not bear to see a man on a stretcher; if any one fainted he was apt to do the same. About the middle of January he collapsed in the trench, was carried out and invalided home; a medical board in London recommended his discharge from the army as unfit for further service owing to neurasthenia. He did not feel inclined to take this verdict; he went to his regimental surgeon, who said that there was nothing the matter with him, and ordered him to his dépôt. It was soon found that he was not able to stand the fatigue of constant drill, and his commanding officer requested him to see me.

He gave me the impression of having a somewhat startled, not to say frightened, appearance. He complained of being easily exhausted, getting short of breath on exertion, often troubled with palpitation and throbbing in the vessels of the neck. He gave way at the knees, and felt that he would like to lean against a support; any extra exertion caused exhaustion, and on suddenly assuming the erect posture he felt faint. He perspired freely and usually felt warm, but often the ends of his fingers became pale and dead. His head usually felt hot, and he was often confused in his thoughts, and incapable of sustained mental effort. He was emotional, and often felt inclined to cry without any reason. There was slight general tremor, muscular irritability, and *tache* easily developed and very persistent. The knee-jerks were excessive. Heart 2 in. to the right, and 4½ in. to the left of the mesial line; sounds short and clear, no murmur, second pulmonic sound rather accentuated. Pulse 84 recumbent, on assuming the erect posture 120, afterwards falling to 96. Blood pressure: diastolic 110, systolic 150 mm. of mercury. Urine 1024, acid, a trace of albumin, lime deficient, phosphates normal; appetite bad. Height, 5 ft. 8½ in. Weight in shirt and trousers, 10 st. 11 lb.; he had lost some weight. I ordered him a month's rest, a liberal diet with plenty of milk food, and a mixture of adrenalin and lime salts.

In this class of cases there is not only over-action of the thyroid but under-action of the suprarenals. The patient often feels faint, and there may be sickness, and even vomiting; on quickly assuming the erect posture he may feel giddy, and there is a great increase in the frequency of the pulse, which becomes small and feeble owing to the blood gravitating into the abdominal cavity and the failure of the vasomotor mechanism to adjust its action rapidly to the altered conditions; and there is frequently orthostatic albuminuria. These phenomena have been aptly termed "cardio-splanchnic paresis" by Albert Abrams. In these cases an abdominal belt worn tightly does good.

HYPOTHYROIDISM.

In many cases of frost-bite, even when the thyroid gland is enlarged, its over-action has disappeared before the patient reaches this country, and frequently there is a state of hypothyroidism, with feeble circulation and cold blue extremities. These cases are easily treated. There are also cases of hypothyroidism in stolid men who would not move a hair if shells were bursting all round them. I had recently a friend under my care—a distinguished officer of a high and well-merited reputation, mentioned in dispatches and honoured by the King. After twelve months' strenuous work, want of rest, and not troubling about his food, he lost over 4 st. in weight. His condition was noticed by his superior officer, who advised him to take a rest. He did not think it necessary, but in obedience to the command he returned to London, was examined by a medical board, which gave him two months' leave.

When I saw him he chafed under the long enforced idleness, but I told him that two months were little enough. I ordered him to bed, told him that I would see him when I thought it necessary, that he was to put on at least 2 st. in weight, otherwise he would require a new uniform. About medicine and diet I would speak to his superior officer, and she would see that my instructions were carried out. Notwithstanding his great loss of

weight I felt confident from his slow, feeble, intermittent pulse and other symptoms that there was deficient thyroid action, and among the remedies I ordered was a 5-grain thyroid tablet daily. He rapidly improved, gained over 2 st. in weight, and was soon fit for plenty of exercise. Before the two months were up he happened to be in London, and sought a medical board, the president of which told him that he could not pass him for foreign service. He then appealed to be examined by the junior member of the board who agreed with his senior. This seems to be a much more common custom in the army than in civil life. When I saw him he was annoyed, as he wanted to be back in the scene of action. I told him that it was his own fault, that he had thought himself too well and had stopped treatment. I had no doubt that his heart had astonished the examiners by intermitting a few times, and that had frightened them. There is an alderman in the city of Liverpool, aged 90, who can still do a long day's fishing and enjoy his dinner with the youngest of us, yet he has had an intermittent heart all his life and was several times rejected for life insurance. I told my friend that he was unfortunate in not having been examined by Sir James Mackenzie, because he might have told him that intermissions do not count, that he had an excellent heart for a recruit, and it might last him till the age of Methuselah if he did not die in the meantime. My own opinion was that his heart was good for this war and somehow on to the next if he did not get in the way of a shell. I told him that he should be like a medical student who always studies the idiosyncrasies of his examiners when going up for an examination. I told him to resume his 5-grain thyroid tablets, to take one every day of his life, and it would save him many medical prescriptions and keep him out of the hands of the modern heart specialist; but for a week before his next medical board he was to take a tablet night and morning and stop tobacco. In the meantime he should go off to Scotland and get some shooting. In a few weeks he passed another medical board, he told me, with flying colours.

I wish to take this opportunity of pointing out that there are large amounts of thyroid preparations on the market more or less useless. It is unfortunate that we should be so much dependent on the reputation of the druggists—wholesale and retail—for the quality of our drugs. Thyroid preparations should contain at least 0.2 per cent. of iodine, but in many samples I have failed to find a trace. Of course, it is easy enough to add iodine to the preparation, but whether the added iodine is as effective as that which should be naturally in the gland is another question. However, I often find that the effects of thyroid are enhanced by the use of iodine at the same time. A favourite prescription with me is a mixture of calcium iodide, tincture of iodine, and the syrup of lactophosphate of lime.

The treatment of these cases is that of hyperthyroidism and hypothyroidism, which every one should know. I see Dr. Florence Stoney strongly recommends *x* rays in cases of hyperthyroidism. I used the *x* rays in many cases with some benefit ten years or more ago, but latterly I have not done so, as all my cases have done very well without the rays. I have no objection to their use, but I think caution should be exercised for fear of overshooting the mark.

REFERENCE.
1 *Practitioner*, April, 1914.

THE report of Major-General William C. Gorgas, Surgeon-General of the United States Army, to the Secretary of War shows that the admission-rate for sickness for the whole army in 1914 was 660 per 1,000, the lowest on record. The rate was highest in China and Panama and lowest in Alaska. The rate for discharge for disability for the entire army was 12.99, as compared with 12.77 in 1913. The death-rate was 4.40, as compared with 5.15 in 1913. Among the 98,649 men stationed in the United States, Alaska, the Philippines, Hawaii, Panama, Porto Rico, and China, there were but 7 cases of typhoid fever; only 2 had received the complete course of vaccine treatment. The admission-rate for tuberculosis had receded to 3.50, and for alcoholism 13.64, both the lowest ever recorded. The rate for malarial fevers was 29.48, said to be "a very creditable showing." The Act of Congress stopping the pay of men incapacitated for service by venereal diseases had held them in check, though the rate was slightly higher than that for 1913.

CLINICAL NOTES ON PENETRATING WOUNDS OF THE ABDOMEN.*

BY

H. H. SAMPSON, F.R.C.S., LIEUTENANT R.A.M.C.

I propose to mention some points in connexion with wounds of the abdomen and to read notes on some cases which have been treated recently at the special hospital at — (5 kilometres behind the firing line).

The extent of the visceral injury caused by a rifle bullet in the abdomen depends to a large extent on the distance which the bullet has travelled before impact. The most extensive wounds are caused when the range is less than 500 yards. Intestine may be torn completely across or show large open wounds with everted edges. Solid organs present radiating lacerations. These wounds, besides being extensive, bleed profusely. With a range of over 500 yards, however, the wounds are more limited in extent, but still bleed freely. As the range lengthens the damage becomes more confined to the actual track of the bullet.

It is interesting to consider the cause of this influence of range on the character of the wound. At first I thought it was due to instability of the bullet which is known to exist during the first portion of its flight. The diagram shows by means of a curve the relation between velocity and range. It shows how rapidly the velocity diminishes during the first few hundred yards of a bullet's flight.

Velocity range curve of rifle bullet.

I think high velocity is the cause of the extensive character of visceral wounds at short ranges. The term "velocity" is meant to include both the translation and the spin of the bullet, and it is probably the latter which is the more destructive force.

The importance of primary haemorrhage lies in the fact that there is little tendency towards spontaneous arrest. When seen, three or four hours after receipt of the injury, small arteries in the wounded bowel are still spurting vigorously. In fatal cases death is almost invariably due to primary haemorrhage. It becomes obvious, therefore, that on this account alone every effort should be made to convey abdominal wounds with the least possible delay to a place which is equipped for their operative treatment.

Peritoneal Perforation without Visceral Injury.

Apart from those cases in which a bullet has only a short intraperitoneal course, it is possible for a bullet to traverse the peritoneal cavity in an area occupied by intestines without causing perforation of the viscera with which it must come in contact. One such case has passed through the hospital.

CASE I.

The entrance wound was in the mid-Poupart line, just below the level of the umbilicus. The exit wound was behind in a corresponding position.

When seen, two and a half hours after the injury, signs of internal haemorrhage were present; the abdomen was rigid and tender. Operation revealed intraperitoneal haemorrhage,

* A paper read before the 3rd Corps Medical Society on March 4th.

which was proceeding from torn ileo-colic vessels adjacent to the caecum, but there was no perforation of any viscus. No sign of abrasion or bruising could be discovered in the small intestine. Bleeding points were ligatured. Recovery was uneventful.

This case is unique in my experience.

Wounds with a very short intraperitoneal course may implicate omentum only. In these cases the omentum shows a great tendency to prolapse through the wound. If the injured omentum is excised and the peritoneum closed, these cases do uniformly well. There is apparently little danger of suppuration occurring in the peritoneal cavity, although the rest of the wound may be badly infected.

Peritoneal Perforation with Visceral Injury.

Wounds of the small intestine are generally multiple, but are usually confined to one segment of bowel.

CASE II.

Cpl. H., of the S. Staffs Regiment, was hit in the abdomen at about 250 yards range. He made the interesting statement that he felt no impact. His right leg suddenly became useless and he fell to the ground. About ten seconds later he experienced agonizing pain in the abdomen. This continued without remission until operation was performed. He arrived at the special hospital within one hour of being hit. The abdomen was then rigid. There was a small entrance wound in the middle line below the umbilicus, and an exit wound, about the size of a halfpenny, in the right buttock.

At the operation seven perforations were found in small intestine. There was a large quantity of free blood in the peritoneal cavity. A segment of lower ileum, measuring 24 in. in length, and containing all the perforations, was excised. End-to-end anastomosis was performed. The peritoneum was mopped dry and then closed without drainage. There was some vomiting for three days, but the patient rallied well. A letter from England six weeks after the injury informs us that he is walking about and feeling quite fit.

Another case of uncomplicated small intestine injury:

CASE III.

Pte. B., Northumberland Fusiliers, was hit by a bullet which ricocheted off an iron roof in the front line trenches. He described the impact as a blow without any pain.

This patient arrived at the hospital in a little over an hour from the time he was wounded. There was a large entrance wound, with bruised edges in the anterior abdominal wall, below and to the left of the umbilicus. At the operation this wound was excised and converted into a vertical incision. A distorted bullet was found lying free in the peritoneal cavity, adjacent to four perforations in small intestine. Intraperitoneal haemorrhage was small in amount; 3 ft. 2 in. of ileum was excised, and end-to-end anastomosis performed. Portions of clothing were found scattered throughout the peritoneal cavity, mostly adhering to omentum. After irrigation with eusol and saline the abdomen was closed without drainage. Some infection of the abdominal wall occurred. This remained local and quickly subsided. The clinical chart indicates the progress. Five weeks after the injury this patient wrote from England to say that he was walking about, but still felt a little weak.

It is surprising how frequently injury to small intestine is complicated by injury to the iliac veins or inferior vena cava. The large arteries either escape damage or more probably produce a fatal result before the patient can be moved; on the other hand, injury to the great veins is often found. This additional source of haemorrhage has in my experience always led to a fatal result.

Wounds of the colon are often complicated by injuries to other viscera. These cases show a high mortality. If, however, the injury is confined to the colon, the outlook is more hopeful provided that operation is performed before widespread peritoneal infection has occurred. The lax wall of the colon allows instant escape of contents, in direct contrast to the small intestine, in which there is little tendency for leakage to occur for several hours.

CASE IV.

Lieut. I. was operated on within one hour of being hit in the left flank. The bullet which caused this wound had travelled more than a thousand yards.

The visceral haemorrhage was slight. There was a single linear wound of the descending colon, with faecal contents soiling the surrounding peritoneum. A Paul's tube was tied into the colon. Rubber drainage tubes were inserted into the subphrenic and iliac regions. Peritonitis remained local and a good recovery ensued. Preparations are now being made in England for closure of the artificial anus.

CASE V.

Lance-Cpl. E. Two and a half hours elapsed between injury and operation.

The descending colon was almost completely severed. There was profuse internal haemorrhage. Division of the colon was

completed. A Paul's tube was inserted into each end. A supra-pubic drain was used in this case. Recovery was rapid and uneventful.

CASE VI.

The case of Private T., Suffolk Regiment, was complicated by the fact that the bullet had entered the abdomen through the innominate bone. There were six perforations of the caecum and ascending colon, varying in size and mostly caused by fragments of bone. The edge of the liver was lacerated, two pieces being completely detached. The edges of the caecal wounds were trimmed, sutured, and invaginated. A drain was inserted into the right flank. The exit wound through the anterior abdominal wall was filled with gauze, which passed down to the wounded liver. A few hours later, during an attack of vomiting, the patient felt something give way. Examination revealed the transverse colon and omentum lying in the dressings. The prolapse was reduced under an anaesthetic. The anterior wound was then completely stitched.

In spite of this unfortunate event the patient made a good recovery. No leakage occurred from the caecum. He wrote the following from Calais three weeks after the injury:

Dear Sir,—I am pleased to be able to write you to say I am getting on quite well, and know you will be pleased to hear this, for I think you thought I'd have a rough journey to pull through. Well, I thought I might with luck, but I was bad for two weeks. . . .

Wounds of the stomach bleed freely, but, if uncomplicated, respond well to operative treatment.

CASE VII.

Corporal D. J., Yorks and Lancs Regiment, was struck in the back by a small fragment of shell. He arrived at hospital two and a half hours after receipt of the injury.

There was a small entrance wound over the left erector spinae at about the level of the first lumbar vertebra. The abdomen was rigid and tender. He had vomited once. Operation revealed perforations of both anterior and posterior walls of the stomach, two perforations of the jejunum close to the duodeno-jejunal flexure, and perforation of the thin anterior edge of the liver. The shell fragment was found imbedded in the diaphragm beneath the left costal margin. The visceral wounds were trimmed, sutured, and invaginated. The only drain used was a wick of gauze down to the wounded liver.

Recovery was uneventful. A message from Calais states that the wounds are healed and the patient well.

Wounds of the Solid Organs.

Wounds of the liver give the best results. In simple perforations haemorrhage is slight; bile drains away for a few days; recovery is the rule. A bullet at short range will split open the liver as though with a knife. In such cases haemorrhage is free, but is easily controlled at operation. Extensive necrosis of the neighbouring liver substance sometimes occurs. This is often seen in fatal cases.

The spleen is seldom injured alone. Its injury is often associated with that of the left kidney, pleura, and lung. The following are the notes of such a case:

CASE VIII.

Rifleman T., 11th Rifle Brigade, felt a sudden blow in the abdomen while lying behind a cart in front of our wire. He arrived in hospital about five hours later, and was then blanched, cold, and collapsed.

There were signs of intraperitoneal haemorrhage. There was an entrance wound in the side over the left lower ribs. On opening the abdomen the peritoneum was found to contain a large quantity of free blood. The spleen and left kidney both showed lacerated perforations. The splenic pedicle was partially severed. The bullet track passed towards the muscles of the back to the left of the vertebral column. Profuse haemorrhage was taking place from the splenic pedicle and from the vertebral region. The spleen and left kidney were excised. The region of the spine was firmly packed, as no bleeding points could be seen. The bullet was not located.

The patient was now so collapsed that the operation was curtailed by simply filling the left loin with gauze and leaving open the centre of the abdominal incision.

Chest symptoms prevented further operative measures until the eleventh day, by which time infection of the loin had already occurred. Drainage tubes were inserted through a posterior counter opening. Eight ounces of sterile blood were aspirated from the left pleura. Signs of septic absorption still continued, and on the twenty-fifth day a rib was resected in order to drain the left pleura. No infection was established.

On the twenty-seventh day the lower posterior wound became faecal. The patient was now in an almost hopeless condition. All the wounds were infected. The temperature averaged 102° F. at night, 100° F. in the morning. The pulse-rate varied from 120 to 140. The respiration-rate varied from 26 to 40. Generalized bronchitis was present. Faeces were constantly escaping from the left loin.

The pleura was irrigated twice daily with eusol and saline. On the thirty-eighth day the temperature remained normal for twenty-four hours for the first time since the injury. From this point improvement was rapid and continuous.

A medical officer from Calais writes to say that the patient was transferred to England nine weeks after the operation, and that he was then in a very satisfactory condition.

It will be noticed that all the cases I quote have had a successful result, and I want to make it quite clear that such cases are looked on rather as brands plucked from the burning than the normal result of these injuries.

One point on which too much emphasis cannot be laid is the importance in these cases of operation at the earliest possible moment. To secure this end perfect co-operation is essential. At the special hospital the operating theatre is kept in constant readiness, and the operation is usually commenced within fifteen minutes of the patient's arrival. But, of course, the most difficult task lies with those responsible for the transference of the case from trench to hospital.

DISCUSSION.

Colonel SKINNER said he was particularly interested, more from an administrative point of view. The speed with which the cases were transferred from the trenches to the hospital greatly added to the chances of recovery. This speeding up rested with the medical officers. He had read Sir A. Bowlby's Bradshaw lecture, published in the *BRITISH MEDICAL JOURNAL*, where he pointed out the greater damage done by bullets when fired at shorter ranges, advancing the theory of compressed air in front of the bullet. Also that the bullet probably has an "explosive" effect. Frequently the bullet also turned over on its course. Its velocity must be imparted to surrounding structures; so much so that Sir A. Bowlby mentioned a case in which the bullet had travelled across the abdominal wall not entering the abdomen, but *post mortem* the bowel was found disorganized. In cases of wounds of back and buttock where the wounds might not suggest an abdominal injury it was wisest to send them into the abdominal and chest department of the field ambulance. He said that Mr. Sampson had had 60 per cent. of recoveries, including cases brought in moribund.

Captain FRASER said that it was often difficult to know when the peritoneum was opened. Recently he had found by experiment that if the blood pressure was low it was probable that the peritoneum was opened. As to injury due to the proximity of the wounded person to the discharged rifle, he described a case in which, accidentally, a soldier was shot through the abdomen at 250 yards without any extensive injury of the bowel. Probably the amount of injury depended a great deal on the position of the bowel when hit. He had tried various kinds of anaesthesia—spinal, ether, chloroform, and lately intravenous ether; here the results are good; not only was there an anaesthetic effect, but a volume of fluid given at once to replace the loss of blood.

Lieutenant-Colonel PICKARD said that he had read in the *BRITISH MEDICAL JOURNAL* a paper in which the damage done by a bullet penetrating the abdomen was regarded as analogous to the splash of a hard substance striking a fluid. He described the well-known trick of throwing a stone up in the air and into a pond trying to make the least amount of splash; here the splash was least when the stone dropped vertically.

Captain SOLTAU asked why Mr. Sampson used a Paul's tube in two of the colon cases and invaginated the wound in the other, and whether he had swabbed out with ether.

Captain McNEE had examined livers pierced by bullets and noticed necrotic changes in the tissues at least two inches from the track. In one kidney case the bullet had pierced the upper pole, and the lower pole showed necrotic changes, although there was not any damage to the intervening tissue. In one 8 in. loop of small intestine he had seen one rosette wound and about nine linear slits; it was highly improbable that the bullet pierced through ten places. He suggested that possibly the slits were due to muscular action.

In reply to Colonel DUNN, Captain FRASER said that he did not use any elaborate apparatus for intravenous injections, only a Lane's bag.

Mr. SAMPSON said, in reply, that in doubtful cases of peritoneal entrance he opened up away from the wound to prevent sepsis. If the compressed air theory of causing damage to abdominal organs was correct more damage at the entrance wound would be expected. The Paul's tubes

were used in the two cases because two-thirds of the circumference of the colon was injured; in the other case the caecum had two or three small perforations. He had not used ether as a peritoneal dressing.

TWO CASES OF REMOVAL OF A BULLET FROM THE UPPER SURFACE OF THE DIAPHRAGM.

BY

E. D. TELFORD, F.R.C.S., CAPTAIN R.A.M.C.(T.F.),
SURGEON, MANCHESTER ROYAL INFIRMARY.

WHILST the lessons of war surgery have thrown much light on the immediate treatment of penetrating wounds of the chest and have prompted some most valuable additions to surgical literature, the later consequences of these injuries have received little notice.

It is a fortunate fact that not a few of these seriously wounded men recover, but some still carry in their chests the agent, whether shell or bullet, which caused the injury. These foreign bodies show a tendency to fall to the bottom of the thorax, coming to rest there on the upper surface of the diaphragm. In this position they may give rise to no trouble and no surgeon would suggest their removal. There are found, however, from time to time cases in which the foreign body is a cause of persistent and distressing symptoms.

In the first case which I report the man's life was made miserable by a constant "pricking" pain, and in the second case the soldier was quite incapable of any exertion, owing to the fact that an increase of respiratory movement beyond the normal produced at once a crippling amount of pain. The two cases are reported, not merely as examples of removal of foreign bodies from an unusual situation, but rather as instances of the help afforded to the surgeon by a simple method of "positive pressure anaesthesia." Thanks to this method, most ably handled by Major A. Wilson, the recovery of a bullet from the pleural cavity was carried out with perfect safety to the patient and was rendered, from the operator's point of view, little more than a minor surgical procedure. The details of the cases are as follows:

CASE I.

G. W. C., aged 24, was wounded in the right side of the chest by rifle bullet fired at long range. The bullet entered through the third right costal interspace three and a half inches from the middle line. Free haemoptysis occurred at once and continued in considerable quantity for twenty-four hours. He reached England at the end of five weeks, and during this time he had much pain in the lower part of the right chest, with frequent cough and daily haemoptysis. Although he stated, on admission to the 2nd Western General Hospital, that he had lost 2 st. in weight since his injury his general condition was excellent. The chest expanded well, and beyond a few moist sounds there was no physical sign of disease or injury. Cough was frequent, and the sputum always contained a little dark blood. The patient, though apparently well and comfortable in a sitting posture, was not able to lie down with ease, and was rendered very breathless by slight exertion. He complained constantly of a "pricking" pain, which he located deep to the sixth right costal cartilage.

Radiographic examination by Captain Bythell disclosed an intact rifle bullet lying on the upper surface of the diaphragm. The bullet was localized at a depth of two inches beneath a point marked over the sixth right costal cartilage and distant one half inch from the line of the right border of the sternum. As the pain continued after a month in hospital, and the patient's condition remained without change, save that the haemoptysis had ceased, it was decided to attempt the removal of the bullet.

Anaesthesia was induced by chloroform, and the tracheal catheter of the Ehrenfried's positive pressure apparatus having been introduced, the operation was carried out under ether vapour introduced under pressure by bellows. Through a curved skin incision the sixth and seventh right costal cartilages were exposed and denuded of their muscular and tendinous coverings, which were reflected downwards in one piece. A portion, 1½ in. in length, of each costal cartilage was then excised. The opening thus made gave abundant access, and through it the parietal pleura was incised in a horizontal direction. A healthy, well-inflated lung presented itself on opening the pleura. The lung appeared and felt absolutely normal, showing no trace of adhesions.

On packing off the lung with a strip of gauze there was disclosed at once on the upper surface of the diaphragm a rounded eminence, in size and shape like the half of a small walnut shell. An incision into this yielded a few drops of turbid fluid, and the bright, unbroken nose of the bullet at once presented. This was seized and extracted without difficulty; it was lying

on the upper surface of the diaphragm, and had become covered and encysted by pale, friable fibrous tissue.

The gauze was removed and the parietal pleura closed tightly by a continuous stitch of fine chromic gut. The tendino-muscular flap was replaced by chromic gut sutures and the wound closed without drain. The colour and general condition of the patient were perfectly satisfactory throughout the operation.

Beyond a slight tracheitis, probably traumatic, which cleared up completely in three days, the convalescence was uninterrupted. The patient was discharged from hospital in four weeks. The "pricking" pain disappeared from the first and the man was able to move freely without breathlessness.

CASE II.

T. J. E., aged 21, was hit by a shrapnel ball at Suvla Bay. He stated that very free bleeding followed the injury—"blood running out of his mouth without cough." He gradually recovered, and does not appear to have suffered from any complications of the injury beyond occasional slight haemoptysis, which continued up to the time of his admission to the Manchester Royal Infirmary, six months after the injury. At this time the chest showed no abnormal physical signs and his general condition was excellent. The scar of the wound of entry lay over the inferior angle of the left scapula. The patient complained of much pain on exertion and located the pain at a point on the tenth left rib, a little in front of the mid-axillary line; he stated that the pain was very severe on deep breathing.

A radiogram by Captain Barclay showed an intact shrapnel bullet lying deep to the rib and fixed in the angle between the diaphragm and chest wall.

Anaesthesia was carried out, as in Case I, by Major A. Wilson with the help of Ehrenfried's apparatus. The operation was of the simplest nature. A portion of the tenth rib, about 1½ in. long, was resected and the pleura opened by a horizontal incision. The bullet was at once evident and was picked without effort off the upper surface of the diaphragm. The edge of the well-inflated lung was well seen, and as far as it could be inspected through the limited opening the lung appeared to be quite healthy and free. The pleura was closed with fine chromic gut.

The after-history of the case was quite without incident; the patient was discharged in a fortnight in excellent condition, having had neither haemoptysis nor his former pain since the operation.

TIME IN SURGERY.

BY

R. P. ROWLANDS, M.S., F.R.C.S.,
SURGEON TO GUY'S HOSPITAL.

THE priceless value of time in surgery is often overlooked, and fleeting opportunities of successful action are frequently allowed to pass with disastrous consequences. Again and again diagnosis is delayed or operation deferred until it is too late either to save life or to secure the best result. For instance, the early signs of grave abdominal diseases are too often attributed to trivial ailments, and a "wait and see" policy adopted until such irreparable damage is wrought that complete recovery is impossible. In such cases the greatest vigilance is required to determine the proper time to "look and see."

Two typical cases of appendicitis serve to illustrate these points. They were very similar in their early signs, but treated differently and attended by very different results.

CASE I.

- (a) Diagnosis made within twelve hours.
- (b) Operation within thirteen hours.
- (c) Appendix removed, gangrenous, but not perforated.
- (d) General condition good.
- (e) Gridiron incision.
- (f) Abdomen closed.

CASE II.

- (a) Diagnosis, abdominal influenza. After nine days, appendical abscess diagnosed.
- (b) Operation after ten days.
- (c) Large abscess opened. Appendix not found owing to the large size of abscess and the grave condition.
- (d) General condition very bad.
- (e) Battle incision, as the surgeon thought he could get more room in this way.
- (f) Drainage on and off for six months; then appendix removed at second operation. Drainage another two months.
- (g) Patient up from fourth day; taken to the country on the ninth day. Quite well three weeks from operation.
- (h) Patient has been in perfect health since the operation.

It ought to be more generally known that the mortality of operations for acute appendicitis increases rapidly with the delay. Operations carried out within twelve hours of the onset of an attack are not more risky than those undertaken in the quiescent period. Still, it is common for the surgeon to be asked to see patients for the first time about the third or fourth day, or even later, when abscess, peritonitis, or other serious complications have developed. Similarly, the mortality of rupture of the intestine is only 15 per cent. when an operation is undertaken within four hours, whereas it becomes 70 per cent. when the operation is delayed until after twelve hours.¹ Similarly, the mortality of perforated gastric ulcer when an operation is undertaken within twelve hours is only about 5 per cent., but as high as 60 per cent. when the operation is deferred until after twenty-four hours. The waste of time is almost as serious and even less excusable with chronic abdominal diseases such as cancer of the stomach or large bowel. For less than one-third of cases of cancer of the stomach when first seen by the surgeon is resection possible, and the result of procrastination is nearly as bad in cancer of the rectum.

Avoidance of Waste of Time at Operations.

Time is frequently wasted during operations. It is clear that in order to get good results the surgeon must do his operations well and thoroughly, but it is often forgotten that to get the best results he must also learn to do them quickly and without waste of time. On the other hand, he must never do shoddy work so that he may be quick. While always conscious of the time element, he must not keep one eye on the clock, but both eyes and all his faculties focussed on his task. His aim must be to get so skilful and familiar with his work that he becomes quick almost without knowing it.

It is obvious that the dangers of most operations increase with their duration. If an operation takes an hour when it can be just as well, or better, done in half that time, the disadvantage of the patient is serious. He has to take much more anaesthetic, which obviously adds to the dangers and discomforts still inseparable from anaesthetics. Further, manipulations and exposure are increased and prolonged with marked increase of shock, of post-operative discomfort, and danger of complications. These points do not need to be laboured, for they are evident enough to every one who has eyes to see. When an appendicectomy takes only ten minutes the patient is hardly ill or uncomfortable in any way, whereas if it takes an hour he is miserable and sore for days.

But the value of smart work is much more striking in grave crises such as operations for acute intestinal obstruction or late peritonitis. It is no exaggeration to say that in these cases the mortality multiplies with the time consumed at the operation. The following case illustrates the value of quick work.

Acute Intestinal Obstruction by a Band: Appendix Adherent to Caseous Mesenteric Gland.

A boy, aged 6 years, was seized with very violent pain in the abdomen on the morning of April 10th, 1911. His father gave him two large doses of castor oil, which failed to have the desired effect. He was admitted into Guy's Hospital with a subnormal temperature, blue, cold, and pulseless. The abdomen was considerably distended, but flaccid. It was full in the flanks, and there was a palpable swelling in the right iliac region. On admission at 8 a.m. he was too bad for operation, and was therefore infused into the axillae.

Operation.—The patient was given ether, and the abdomen was opened at 9.30 a.m. The lower part of the right rectus was displaced inwards. The peritoneum seemed to be purplish and clearly contained blood. It was opened, and a large amount of sanious fluid escaped, showing that the condition was one of intestinal obstruction and not appendicitis. Dark purplish, but not gangrenous, coils of small intestine were at once seen. Several coils were withdrawn, and a band was seen consisting of the appendix adherent to a caseous mesenteric gland. This was astride the lower end of the ileum, close to the caecum and completely obstructed it. The adhesion to the tip of the appendix was divided, and the empty caecum drawn away from its former position, which was unusually high. The abdomen was then closed with through-and-through salmon-gut sutures. The operation lasted seven minutes (the patient was only in the theatre ten minutes). He was not much worse at the end of the operation, but the infusion which was carried on throughout the operation was continued. Pituitary extract was injected in 5-minim doses. The patient rapidly recovered.

Our forefathers before the introduction of anaesthetics had no doubt about the value of rapid operating, but later

a mischievous belief became common that, with anaesthesia, time did not matter. Unfortunately, there are still too many who appear to share this opinion. They waste valuable time—which belongs more to their patients than to them—in many different ways. It may be profitable to consider how to avoid some of this serious waste of time.

1. *By Making All Possible Preparations and Calculations Beforehand.*—The skin is always prepared before the patient comes to the operation table. All necessary instruments, ligatures, and sutures threaded on needles are ready for use before the patient is completely under the anaesthetic. The surgeon and his assistant are quite ready to begin as soon as the patient is satisfactorily under the anaesthetic. The surgeon thinks out the various steps of the operation beforehand as far as this is possible. He makes up his mind quickly what he wants to do, and does it without unnecessary delay.

2. *By Improving and Simplifying the Technique of the Operation in Every Possible Way.*—Here a sound knowledge of anatomy and surgery and constant practice are essential. As regards the knowledge of anatomy and surgery, it is assumed that the surgeon will not undertake an operation unless he is familiar with the anatomy of the part and the details of technique of the operation which he contemplates. It is clear from the results of some of the operations for hernia recently undertaken that the operators were not familiar with the anatomy of the inguinal canal, for several cases have come to my notice of recurrence within a few months owing to the inguinal canal never having been opened. It is true enough that a surgeon has to get practice to learn, but a sound knowledge of anatomy and surgery, together with diligent practice on the dead body, will carry the beginner far. Every one who wants to become a good and quick operator should practise on cloth all varieties of knots and sutures. In this way he will become expert and competent in a short time. It is often painful to see a man hesitating about his knots, and uncertain about his method of sewing. Many men waste time by making the skin wounds too small, and thus allowing themselves only an unsatisfactory view of the parts. As a rule, except on the exposed parts, such as the face, there is no object in making a small skin wound. Much time is also wasted in blunt dissection instead of clean cutting. Both of these faults not only waste time, but add to the shock and local damage. Good haemostasis saves much time. For instance, in most operations on the limbs a tourniquet is used, so that no bleeding occurs to obscure the view and delay the work. In other operations the main artery to the part is temporarily clamped or tied. For instance, the carotid is often clamped while operating on the neck. In most operations the important vessels can be secured before they are divided. Complicated instruments are to be avoided, for they waste time. For instance, a needle holder has no advantage in the majority of operations, but adds to the number of movements necessary for a given result. It is, of course, an invaluable and necessary instrument when working in a pit like the bottom of the pelvis. In ordinary work the finger and thumb are much more accurate, adaptable, and infinitely quicker. If one were to judge by the instruments they use, it might be concluded that some surgeons enjoyed making operations as difficult and prolonged as possible. The same may be said of many complicated methods, which are rarely as efficient as simpler ones. Continuous sutures save much time, and they are more effective and haemostatic than interrupted. In grave emergencies an excess of fine detail in sewing is often to be avoided; the sewing should fit the occasion. Lives may be lost through the waste of time involved by an over-refinement of technique.

3. *By Concentrating the Full Attention upon the Operation.*—This is not the time for considering and talking of other matters, nor even for explaining the various steps of the operation to the inquiring stranger. The latter must be content to watch until the operation is completed.

A PRELIMINARY NOTE ON THE NATURE AND TREATMENT OF CONCUSSION.

BY

T. E. HARWOOD, B.A. Oxon., M.B., Ch.B. Edin.,

RESIDENT OPHTHALMIC OFFICER, THE KING GEORGE HOSPITAL, S.E.

In the treatment of neurasthenic conditions arising in the course of the war one point would appear to have attracted but little attention. Almost every patient will be found to have more or less difficulty with reading. This is usually taken for granted and passed over as a mere incident. In reality it gives a clue to the most efficient treatment of such cases, from whatever cause arising.

The living body may be compared to an electrical system, which may break down owing to faults either in the circuit or in the battery. An organic nervous lesion may be compared to a break in the circuit, a functional nervous condition to a lowered efficiency of the battery, affecting the whole circuit, but usually showing its effects more markedly in some parts than in others.

The patient who has had a head injury involving the loss of brain substance usually shows signs and symptoms that are recognized as those of an organic lesion, but he also shows signs and symptoms which cannot be directly associated with the definite organic lesion and are the result of the shock to the nervous system as a whole; a functional condition is superimposed upon the organic. A destructive lesion of the left lingual gyrus, for instance, does account for blindness of a quadrant of both fields of vision; it does not account *per se* for giddiness, nausea, tremors, palpitation, dyspepsia, functional paralysis, neuralgia, and joint pains lasting, perhaps, for months. In cases of concussion without injury the same group of functional conditions occurs, and such cases differ from the neurasthenias of everyday life only in severity and apparent suddenness of onset, the cause being the same in every case—namely, a lowered efficiency of the battery.

Neurasthenia, in the widest possible sense of the term, corresponding to a lowered efficiency of the battery, is a general condition affecting every function, organ, and tissue of the body, though its effects are usually more marked upon some one function or organ or tissue than upon the rest, so that different names or labels become attached to different forms of the same underlying condition. The ciliary muscle is affected equally with the rest of the body, with the result that the smallest errors of refraction frequently become almost insuperable difficulties. Asthenopia following head injury or concussion is rarely due to any definite injury of the eye or its nerve supply, but simply to an inability of the ciliary muscle to make the smallest effort. Even a 0.25 cylinder may in these conditions alter the visual acuity from less than $\frac{1}{6}$ to $\frac{1}{2}$; and in most cases the visual acuity can readily be shown to depend simply upon the refractive error. The patient who has had a sudden paresis of an external ocular muscle may have diplopia, headache, giddiness, nausea, and vomiting; the physician is satisfied as to his diagnosis because it stares him in the face. Paresis of the ciliary muscle does not, but its results are frequently the same, with the added possibility that the conjunction of these symptoms with a hypermetropic disc may suggest an intracranial tumour.

If neurasthenia corresponds to a lowered efficiency of the battery it is obvious that there are two lines of treatment—the one to increase the efficiency of the battery, say by suggestion; the other to give the battery less to do, say by putting the patient to bed. A patient suffering from head injury or shell shock is usually put to bed and rested in every possible way; almost the only organs of his body upon which any constant voluntary effort falls are his eyes. At first the mere stimulus of light may be intolerable to him, and he lies with his eyes shut as far as possible; later he may be comfortable except when he changes his position. His next step is probably an attempt to read, and the difficulties of near vision are added to those of distant vision; when he gets up more frequent changes of position cause a recrudescence of his giddiness, headache, and nausea. In fact, throughout his convalescence his chief energies are, consciously or unconsciously, being spent upon his eyes, because without the use of his eyes he can do little or nothing, and

during all his waking moments a large proportion of his diminished available energy is being spent upon them, the result being that the rest of his body is starved. Various functional effects follow, and the patient falls a ready victim to organisms normal to the body and their toxins. But by correcting the refractive error the work which the eyes have to do can be reduced to a minimum and a much smaller strain put upon the battery. It cannot be too strongly insisted upon that refractive errors are almost universal, and only require care and patience to find. The effect of accurately correcting them in acute cases is dramatic, and if patients with head injury or concussion are not rapidly improving, their refraction should be estimated under atropine (unless it is contra-indicated) while they are still in bed, and accurate glasses supplied as soon as possible. If a stock of circular cylinders with frames to fit them is kept, this can be done immediately; spheres may be fastened in front of cylinders with thin strips of strapping. The glasses should be stopped as soon as possible for distant vision, but continued much longer for near work.

It is absurd to ascribe neurasthenic conditions to errors of refraction, but refractive errors are basic factors, and their accurate correction breaks a vicious circle. The facts are hard to explain except on the hypothesis that there are two centres of energy, each supplying all the structures of one half of the body. Unilateral symptoms—for example, functional hemiplegia, hemianæsthesia, hemianosmia and hemiægeusia, unilateral nerve-deafness, headache and head noises, the more exaggerated knee jerk, the more functionally limited visual field, unilateral will, with very few exceptions, be found to be on the side of the eye with the more work to do; usually on the side of the eye with the greater of two different errors or with the more abnormal of two approximately equal errors.

The earlier the refraction is corrected the easier it is to do, the more likely the correction is to be effectual, and the more willing the patient is to wear the glasses. The nature of the error does not matter in the least—everything depends on the accuracy of the correction. The object to be aimed at it is to leave a minimum, and as far as possible equal, amount of error for each eye to correct. An over-correction does no good and may do a great deal of harm. If the astigmatism is not fully corrected the probable result will be the conversion of, say, a compound hypermetropic astigmatism into an artificial compound myopic or mixed astigmatism. It is useless to attempt this kind of work without an unlimited supply of patience. Atropine is almost essential, and no fixed standard, such as $\frac{1}{2}$, should be accepted. Most patients can be made to read $\frac{1}{2}$ and many $\frac{1}{4}$ under atropine. It is absurd to say that a patient will read $\frac{1}{2}$ when he comes out of atropine; very likely he will, but at the expense of his nervous system. With simple astigmatism the results are almost certain; mixed or compound cases are much more difficult. Whether the patient is complaining of his eyes or not makes no difference. Giddiness is far more diagnostic of ciliary paresis than is headache. It is no great compliment to Weir Mitchell to adopt his system of rest cure, which, with suggestion, is the usual line of treatment in these cases, and to ignore his pioneer work on the paramount importance of eyestrain.

My work is on the lines of that of Dr. George M. Gould of Philadelphia; but I have formed my conclusions entirely on my own results, and I only read his *Biographic Clinics* a few weeks ago.

A CONFERENCE on sanitary administration under war conditions will be held in London by the Royal Sanitary Institute on June 8th and 9th. The subjects selected for discussion in the mornings are the maintenance of the standard of municipal sanitation and the Mental Deficiency Act. Visits will be paid to certain public works in the afternoons.

A SOCIETY for the scientific study of infancy from the biological, psychological, and clinical points of view has recently been established at Naples on the initiative of Professor Cacace, founder of the Istituto Nipioigenico, which comprises departments of medical consultations for infants, *gouttes de lait*, crèches, maternity wards, provident funds for mothers, instruction in motherhood and puericulture, and laboratories for the examination of milk, and the biological and hygienic study of sucklings.

THREE CASES OF PAROXYSMAL HAEMOGLOBINURIA IN SOLDIERS.

BY

DESMOND MACMANUS, M.R.C.S., L.R.C.P.,

CAPTAIN R.A.M.C.(TEMP.),

ATTACHED INNS OF COURT OFFICERS' TRAINING CORPS, BEREKHAMSTED.

In view of the comparative rarity of this condition the following cases possess considerable interest. All three men were in the early stages of their military training and paraded sick owing to discoloration of the urine, which, coupled with a feeling of great exhaustion, caused them considerable alarm.

CASE I.

Private H., aged 18. No history of venereal disease. Woke up one morning after night operations feeling very weak and shivery, and noticed that his urine was red in colour. His temperature was 100.8°; no physical signs could be detected, except that the spleen was just palpable. The urine was dark brown and contained heavy deposits; it showed the presence of albumin, and gave a positive reaction to the guaiacum test. On microscopic examination a few red corpuscles, a quantity of amorphous pigment, and some bladder epithelium were seen. Spectroscopic examination showed the absorption bands typical of methaemoglobin.

The patient was put to bed with hot-water bottles and given warm drinks. After twenty-four hours the urine was clear, and he felt quite well, though weak. He was given an iron and arsenic tonic, and returned to special duty in a few days. He had no recurrence while under my observation.

CASE II.

Private S., aged 32, had suffered from malaria in 1912 while in the tropics. He had led a sedentary life until enlistment. His attack started suddenly with severe lumbar pains after exposure to cold and wet.

On examination he had a temperature of 102.2°, which, however, quickly fell after rest in bed. There were no abnormal physical signs; the spleen was impalpable. His urine, which was examined both microscopically and spectroscopically, presented the same characteristics as in the preceding case, differing only in specific gravity. A blood examination showed a leucocytosis of 9,800. This man continued to pass blood-stained urine for forty-eight hours. He was given similar treatment, and was soon back at work. He is now in Mesopotamia, and when I last heard from him had had no recurrence.

CASE III.

Private J., aged 28, had had a similar attack previously in civilian life. On this occasion the onset was sudden, accompanied with great exhaustion. His temperature was 102° and the spleen just palpable. After being put to bed he complained of an intense "itchiness" all over. The urine had the same physical, microscopic and spectroscopic characteristics as previously described, and he also had a leucocytosis.

He recovered from this attack in twenty-four hours, but had a relapse about six weeks later. He was eventually put to clerical work and has not suffered since.

In all these three cases the exciting cause was apparent exposure to cold coupled with considerable bodily exertion. In none was there any admission of syphilitic taint. The Wassermann reaction was not done in any of the cases. On examining the cases admitted into Guy's Hospital during the last few years, I find that in the last three the Wassermann test was performed, and was positive in all of them. Malaria is cited by some authorities as an etiological factor, and Case II had suffered from this disease. It is interesting to note that in none of these cases was the initial temperature under 100°, and that in none of them did the urine clear up under twenty-four hours. This apparent severity was, no doubt, due to the considerable exposure and exertion undergone.

The most generally accepted theory of causation is that a haemolysis exists in the blood of these cases, the amoceptor of which will only unite with the red blood cells in the presence of the complement, and at a low temperature. This low temperature was present in all the cases under consideration. It seems to me that these men, all of whom had lived sedentary lives prior to enlistment, when thrust rapidly into the full stress of military life, had given way at the weakest point, which in them happened to be in the blood. I am convinced that were a more gradual system of early training recruits more generally adopted many fewer would succumb and be invalided out of the service. In Cases I and II the patients were put back and allowed only the minimum of physical effort, which was increased by degrees with the view of more thoroughly hardening them and enabling them to with-

stand both cold and exposure. So far, after nearly a year in both cases, neither has to my knowledge suffered a relapse.

HEART-BLOCK IN JAUNDICE.

BY

R. D. RUDOLF, M.D. EDIN., F.R.C.P.,

LIEUTENANT-COLONEL C.A.M.C.

THE following case occurred in a hospital some months ago, where I saw him with Lieutenant Joscelyne. It was the first example that I have come across of heart-block complicating jaundice, and I now put it on record, after reading Dr. J. Davenport Windle's paper.¹ Dr. Windle states there that he does not accept the commonly-made statement that the heart tends to be slow in jaundice, and with this I fully agree. For years in civil hospital practice I have noticed this, and since coming to France, where we see a good many cases of jaundice, the point has been brought more home to me than ever. But Dr. Windle goes on to say that in his knowledge heart-block has never been demonstrated, and hence my reason for now recording the following case. It was, as will be seen from the tracings, one of partial heart-block, and, strange to say, was at once relieved completely, and, as far as we were able to observe, permanently, by a single dose of atropine.

An officer, aged 43, was admitted to hospital suffering from jaundice. It had existed for about two weeks, and was preceded by nausea and vomiting, but no pain. There was no history of syphilis, but the patient admitted having drunk too freely for years.

FIG. 1.

He looked ill and was deeply jaundiced. There was no oedema at first, but there was some before he left for England. There was some slight irregular fever. The liver was not palpable and seemed small on percussion. The spleen could

FIG. 2.—Immediately after exercise.

not be felt. The urine contained no albumin on several examinations. The pulse could be felt to be irregular in that it often missed beats, and no heart sounds occurred in the pauses. A little exertion, such as sitting up in bed several times, caused

FIG. 3.—Twelve minutes after atropine.

it to become quite regular. Tracing 1 shows the pulse while the patient was at rest. The a-c interval will be seen to get longer and longer until it is more than 3 seconds, and then the ventricle misses. After this pause the a-c interval is shorter at first, but gets longer and longer until another ventricular miss occurs. Figure 2 shows the action after the exercise described. The a-c interval is still too long, but the stimulus gets through in time and the ventricle does not miss, so that the pulse is regular for a period. It will be seen that this slight exercise caused the auricular rate to fall from 72 to 68. Next day tracings were again taken and showed these same features. Then 1/60 grain of atropine sulphate was given hypodermically,

and tracings were taken every two minutes for an hour. The first effect of the atropine appeared to be a slowing of the auricular rate, which fell from 72 to 64 (as measured in the tracings), and the ventricular missings were very frequent.

FIG. 4.—After fourteen minutes.

Tracing 3 shows the state of things twelve minutes after the administration of the drug. But at fourteen minutes, the auricular rate being only 60, the heart had become quite regular, although the *a-c* interval still remained much too long (Tracing 4). At twenty minutes the pulse was 68 and quite regular and the *a-c* interval was shortening, and at thirty minutes after the giving of the atropine, as seen in Tracing 5,

FIG. 5.—Thirty minutes after atropine.

the pulse was regular (76) and the *a-c* interval of quite normal length. The pulse was then taken by the sister for another three hours, and was always regular, and ran as follows:

12.50 p.m. ...	72	2 p.m. ...	72
1.10 " ...	72	2.10 " ...	72
1.10 " ...	74	2.20 " ...	70
1.20 " ...	76	2.30 " ...	72
1.30 " ...	72	3 " ...	76
1.40 " ...	74	4 " ...	76

The general condition became rapidly worse, and he soon developed oedema and ascites. The pulse, however, remained absolutely regular. He was very anxious to get to England, so was permitted to travel there, as the outlook in any case seemed bad.

This case was, of course, not one of simple catarrhal jaundice, but was probably one of organic disease (probably malignant) of the liver. I have no evidence that the condition of heart-block did not exist before the jaundice, except that the patient assured us that he was very fit and quite up to all his work as an officer at the front. The fact that the block was partially relieved by gentle exercise and completely and, as far as we were able to watch the case, permanently, by a single dose of atropine, would all point to the probability of the delay in transmission of stimuli through the auriculo-ventricular bundle being due rather to vagal origin than to any organic disease there. The patient had not been taking digitalis for days before the tracings were taken.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

BRADYCARDIA ASSOCIATED WITH JAUNDICE.

DR. WINDLE's paper on the heart's action in jaundice, in the JOURNAL of January 22nd, 1916, prompts me to put on record the following case:

A male, aged 17, came to see me on September 7th, 1914, suffering from well-developed jaundice. This may have been of the epidemic type, as another younger member of the same family developed jaundice some weeks later. He had not been under observation at the onset of the illness, but the initial symptoms appear to have been slight, and he had not kept his bed. The pulse was slow (40 to 44) and irregular. Later in the day he was seen at home and a pulse curve taken. Unfortunately it was not possible to get a tracing of the jugular pulse, so simultaneous curves of the apex beat and radial pulse were taken. The rate was just under 39, and the cardiogram demonstrates that

there were no premature beats; the pulse and ventricular rates were the same. This was confirmed by auscultation of the heart.

In the absence of a venous curve the presence of heart-block cannot be absolutely excluded, but it is improbable, for the following reasons: (1) In a later portion of the curve the rate is rather higher and there is marked (sinus) arrhythmia; (2) as the jaundice passed off the heart-rate

FIG. 1.—Simultaneous curves of the apex beat and radial pulse.

rose gradually. At visits to see me the rate was 43 on September 9th, 45 on September 11th, 55 on September 14th, and 56 on September 19th. It may be concluded, therefore, that, associated with the jaundice in this patient, there was a total bradycardia of high grade with a variable degree of sinus arrhythmia. His normal pulse-rate appears to be about 60. He belongs to a family several members of which have a rather slow heart-rate, his mother's being sometimes as low as 30.

Dr. Windle suggests that the arrhythmic bradycardia in these cases is not caused by the jaundice, but is the same as that which is commonly met with in young people after febrile illnesses. This may be so, and there is merely the apparent relation of the heart-rate to the degree of jaundice in my patient to suggest a causal connexion between the two. It is difficult to prove or disprove, but that the pulse-rate should not decline till the appearance of the jaundice is only what one would expect, since the latter is the outward sign of the entrance of bile into the blood circulation. Even if the jaundice appeared before the fever had subsided and the pulse had fallen, one might not be justified in concluding that bile salts do not lower the heart-rate. The fever, whatever its cause, is an opposing factor which may more than neutralize the supposed retarding influence of bile salts, just as it is difficult or impossible materially to alter the heart-rate in fever by means of digitalis.

Bradycardia is believed to be almost exclusively associated with the catarrhal type of jaundice. This is possibly due to the fact that this disease is much more common in young people, in whom apparently the retarding mechanism of the heart is very sensitive. The frequent occurrence of slow sinus arrhythmia in such patients after even slight febrile illnesses is evidence of this.

HULL

E. E. LASLETT, M.D. B.Sc.

AMOEBAE IN URINE IN A CASE OF INFECTIOUS JAUNDICE.

WITH respect to the memorandum on the occurrence of amoebae in the urine of a case of infectious jaundice, recorded by Lieutenant-Colonel Ward, Dr. Coles, and Captain Friel in your issue of April 8th, on page 526, may I point out that an organism called *Amoeba urogenitalis* was described by Baelz in 1833? The species was found in masses in the sanguineous urine as well as in the vagina of a patient in Japan. The amoebae when quiescent had a diameter of about 50 μ , and exhibited granular cytoplasm and a vesicular nucleus.

Similar cases were also reported between 1892 and 1895 by Jürgens, Kartulis, Posner, and Wijnhoff. Jürgens found small mucous cysts, containing amoeboid bodies, in the bladder of an old woman suffering from chronic cystitis; they were also found in the vagina. Kartulis observed similar organisms in the sanguineous urine of a woman suffering from a tumour of the bladder; the organisms measured 12 μ to 20 μ , and exhibited slow pseudopodial movements, and a nucleus and vacuoles were seen after staining. Posner's case, a man, also passed blood stained urine, in which amoeboid granular bodies, about 50 μ by 28 μ , were present. The amoebae exhibited change of shape, and contained one or more nuclei as well as red blood corpuscles. The patient was under observation for over a year, during which the attacks recurred, and Posner concluded that the amoebae had penetrated into the pelvis of the kidney. Wijnhoff observed four cases of amoeburia in Utrecht, and Jeffries (1904) found similar

cases in the United States. During the last two years, I learn from friends in the Anglo-Egyptian Sudan that a few cases with amoebae in the urine have occurred there. These amoebae might be considered, nowadays, to belong to the genus *Endamoeba*.

In view of the above facts, the provisional name *Amoeba urinae granulata* seems hardly necessary.

Lecturer in Parasitology, Liverpool School of Tropical Medicine.

Reviews.

DISEASES OF THE NOSE AND THROAT.

WE said of the first edition of Sir STCLAIR THOMSON'S treatise on diseases of the nose and throat, which appeared in 1911, that it was at once the fullest and the clearest work on the subject in the English language. A second edition¹ has recently been issued, and we see no reason to modify the opinion expressed as to the first. The book in its present form bears on almost every page the marks of very careful revision, and a considerable amount of new matter has been added. An excellent account of suspension-laryngoscopy—the latest development in the methods of direct inspection of the larynx—is given. The procedure of nerve-blocking by the injection of novocain around the superior laryngeal nerves for the production of local anaesthesia is fully described. The method is said to be very useful in cases of great irritability of the larynx, and particularly as a means of preventing pain in that most distressing condition, the dysphagia of tuberculous laryngitis. Aspergillosis of the accessory sinuses receives more adequate treatment than it did in the previous edition, and the indications for the use of salvarsan are more fully set forth. The intranasal operation for drainage of the frontal sinns is described in detail. There are new sections on intranasal dacryocystostomy and on the nasal route to pituitary tumours. The chapter on removal of the tonsils has been entirely rewritten. There is considerable difference of opinion among laryngologists on the question whether only the projecting part of a diseased tonsil should be sliced off or the whole gland extirpated. British and American specialists are mostly in favour of the radical procedure. The subject is of greater importance than might seem at first sight, for disease of the tonsils is the cause of much immediate suffering and possible future detriment to the patient. It is also troublesome to the doctor, and we remember hearing a very distinguished surgeon of the mid-Victorian period declare that he would rather do three lithotomies than one tonsillectomy. To those who can recall the barbarous methods of that time the present manner of dealing with diseased tonsils represents a striking advance in surgery. Sir StClair Thomson gives a lucid and impartial exposition of the relative advantages and disadvantages of the different methods now in use. But, indeed, he everywhere handles debatable matters in a judicial spirit that makes his book a trustworthy guide to practitioners and students. The illustrations, many of which are new, add materially to the value of the book.

CANCER OF THE STOMACH.

AN elaborate clinical and pathological study of carcinoma of the stomach has recently been published by Drs. SMITHIES and OCHSNER,² based on a series of 921 cases seen during the last decade and buttressed with numerous references to the recent literature of the subject. The authors break little or no new ground in their survey, but perform a most valuable service in bringing together the indications for diagnosis and treatment in this most serious affection and casting fresh light on other points of minor importance. Previous writers, for example, have found cancer of the stomach to be a little commoner in females than in males; in this series of American cases

however, the males were just over three times as many as the females. As regards age, 350 of the patients were aged from 50 to 59, and 85 per cent. were from 40 to 69 years old. The authors find that material prosperity, or the tendency to over-eating, promotes the occurrence of carcinoma of the stomach; trauma may have been a contributory cause in only 21 of their patients, and a family history of cancer was obtained in 8.5 per cent. In a series of 566 cases specially examined for the purpose, it appeared that there were good reasons for supposing that a gastric ulcer had preceded the cancer in no fewer than 60.5 per cent.; they do not attempt to estimate the percentage of the patients with ulcer of the stomach in whom the ulcer subsequently becomes carcinomatous. Very full accounts of the morbid anatomy, symptomatology, clinical manifestations, diagnosis, and x-ray appearances in cancer of the stomach are given. So far as treatment is concerned, the authors strongly urge laparotomy and excision of the ulcer or growth wherever possible in all cases in which there is reason to suppose that a carcinoma is present. Dr. Ochsner gives full descriptions of the operations advised for the complete or partial excisions, the curative or palliative surgical treatments, he has found most practical and efficacious. The book is full of interesting details, and is well illustrated; the authors write clearly and temperately. Their work may be warmly recommended to the attention of all surgeons and physicians; it ends with an excellent account of the non-surgical treatment of the disease.

EYES FOR THE LAYMAN.

THE eyesight is by common consent the most precious of the senses. During infancy and childhood much can be done by carelessness and ignorance to injure or even destroy the sight, and it is only in the last few decades that public attention has been at all adequately directed to the proper protection and conservation of the vision of children. Much still remains to be done; the British public still has a great deal to learn about the elementary physiology of the eyes and the precautions that should be taken in every school and every home to prevent the young from misusing their eyes. An ophthalmic surgeon of special experience in this matter, Mr. N. BISHOP HARMAN, has quite recently published an admirable account³ of the dangers and disasters threatening the eyes of children; the book is one that should be very widely read. It is written in simple language that any layman should be able to understand, and in spite of its simplicity succeeds in giving a clear and complete presentation of the subject. Its successive chapters deal with topics familiar to all of us, such as sore eyes, pink eye, eye-strain, astigmatism, short sight, squint, and the great question of spectacles; later chapters deal with the lighting of rooms, the best arrangements for illumination when reading, writing, and work have to be done, and other like subjects. We can strongly recommend this book to the attention of the general public. It fills a long-felt want, and fills it to perfection, for it leaves out none of the essentials of the subject and is written in a style that is both convincing and attractive.

MEDICAL JURISPRUDENCE.

IN reviewing the first edition of Dr. W. G. AITCHISON ROBERTSON'S work on *Medical Jurisprudence, Toxicology, and Public Health*,⁴ we referred to it as the most remarkable case of condensation within our experience. This was in 1908, and now in 1916 the third edition is before us with two new chapters (Medical Inspection of School Children and Diseases of Occupation). We then expressed a fear that such a concentrated diet might produce mental indigestion in students, but the fact that three editions have been called for in eight years proves our fears groundless. Is it advancing years bringing a wider survey of students' educational needs, or is it the reviewer's increasing experience as an examiner that has brought him in the interval to a more appreciative frame of mind as regards the merit of the book? We do not know, but

¹ *Diseases of the Nose and Throat, comprising Affections of the Trachea and Oesophagus: A Textbook for Students and Practitioners.* By Sir StClair Thomson, M.D., F.R.C.P. Lond., F.R.C.S. Eng. Second edition. London, New York, Toronto, and Melbourne: Cassell and Co., Ltd. 1916. (Med. 8vo, with 22 plates and 337 figures in the text. 25s. net.)

² *Cancer of the Stomach.* By F. Smithies, M.D., with a chapter on the Surgical Treatment of Gastric Cancer, by A. J. Ochsner, M.D., LL.D., F.R.C.S. Philadelphia and London: W. B. Saunders and Co. 1916. Roy. 8vo, pp. 522; 106 figures. 24s. net.)

³ *The Eyes of our Children.* By N. Bishop Harman, M.A., M.B. Cantab., F.R.C.S. London: Methuen and Co., Ltd. 1916. (Fcap. 8vo, pp. 129. 1s. net.)

⁴ *Manual of Medical Jurisprudence, Toxicology, and Public Health.* By W. G. Aitchison Robertson, M.D., D.Sc., F.R.C.P.E., F.R.S.E. Third edition. London: A. and C. Black, Ltd. 1916. (Cr. 8vo, pp. 658; 51 figures, 1 plate. 10s. 6d. net.)

can only say that we could almost hope to see it made the standard textbook for students on the subjects dealt with. Everything is there that a student ought to know, and that, too, in just the right perspective, and expressed so clearly and so pleasantly that we have been beguiled into reading nearly the whole work. There is, of course, a large superstructure to be built on the foundation here supplied, and that experience alone can bring about, but it is safe to say that no part of such superstructure need be without a sure foundation if a student has carefully followed Dr. Robertson's words and meaning.

NOTES ON BOOKS.

THE Research Department of University College Hospital Medical School has recently issued⁵ a collection of ten papers dealing with work done beneath its roof in the years 1914-15. These papers deal with pathological and physiological subjects of considerable variety, and have all appeared previously in scientific periodicals. Dr. Lewis, one of the directors of the department, contributes, with Mr. Barcroft, a further account of the dyspnoea that may accompany a reduction in the normal alkalinity of the blood and the various symptoms that may be associated therewith. Dr. Bolton, in a paper first appearing last year in the *Journal of Pathology and Bacteriology*, gives an elaborate account of the relation of the acidity of the gastric juice to the production and maintenance of gastric ulcer. Other papers of no little interest will be found in this collection, which contains evidence of much solid labour.

Dr. MCCARRISON has republished in book form five of his papers on *Goitre and Cretinism*⁶ that have already made their appearance in the *Indian Journal of Medical Research*. Several of these have already been noted in the *BRITISH MEDICAL JOURNAL*. As is well known, Major McCarrison has done much to establish the fact that many cases of goitre are due to the consumption of infected drinking water, although it is true that the actual virus of goitre has hitherto escaped isolation in the laboratory. This reprint is of particular value because the originals of the five articles appearing in it must be inaccessible to the majority of medical men in this country.

The *Indian Manual of First Aid*⁷ of Lieutenant-Colonel BLACKHAM has reached its twelfth edition. It gives a capital account of the subject, and naturally has plenty to say about the special accidents to which dwellers in India are exposed. It should be in the hands of all English-speaking foreigners in India.

A singularly depressing and untimely picture of life in the Russian army is furnished by a recently translated Russian novel, *The Duel*.⁸ Its author, we are told, was born in 1870, passed through the cadet school and military college at Moscow, entered the army as lieutenant in 1890, and resigned after seven years to devote himself to literature. The hero of the novel is Sub-lieutenant Romashov, a weak-kneed idealist who could never have made a soldier. The novel is devoted to describing the way in which the hero undoes himself by witlessness, wine, and women. At the end of the book the heroine succeeds in selling both herself and her lover's life by a single stroke of perfidy. Not one of the characters, male or female, can be described as normal; all have their repulsive features, all are grossly vicious in public or private—or both; from the military point of view all are incompetent but one. The Russian army is described as composed of "those defenceless victims of their own ignorance and brutal coarseness, of the officer's heartless indifference and cruelty, of a humiliating systematic slavery; but the most horrible of all, however, was the fact that not a single officer . . . saw in these stereotyped crowds of slaves anything beyond mechanical quantities bracketed under the name of companies, battalions, regiments, etc." We read that the Russian "soldier's courage is inspired by drink. Military discipline still exists, but it is based on threats and dread, and undermined by a dull, mutual

hatred." It will be seen that the author takes a consistently gloomy and depressing view of the Russian army and all its works. Yet nothing could have given him the lie better than the whole course of the present war upon the Eastern front. Nothing could have shown up the inherent falseness of the author's views about the Russian army better than the magnificent spirit and solidarity with which it has borne up for twenty months against the onslaughts of the far better armed and prepared Central Powers. The book has been fairly well translated. It is one for our pessimists to read, and read with pleasure; they will overlook the fact that its whole thesis is being contradicted daily by the test of war.

The world knows very little of what actually goes on at the front in France day by day. Spies are many, information of great value to the enemy is easily picked up, and the Allied Governments have rightly done their best to screen their military operations in detail behind an impenetrable veil of secrecy. An American journalist, however, has been given the opportunity to inspect for himself the conduct of warfare in and behind the French trenches. As he says, "To obtain me permission to see the French fighting machine in action required the united influence of three Cabinet Ministers, a British peer, two ambassadors, a score of newspapers—and the patience of a Job." He gives an excellent account of his experiences in a book recently published,⁹ with scores of most illuminating photographs. He was most struck by the organized efficiency of the French, the profound conviction of victory with which they are animated, and the incredible horrors of modern warfare in the combinations of slaughterhouse and sewer known as trenches. He refers again and again to the waste and desolation left by the passage of war through countryside and village. He has been unfavourably impressed by the lack of seriousness with which the British make war—an old complaint often brought against us in past centuries, both inevitable and true. The book gives an admirable picture of modern warfare in its general aspects, and for that reason should be widely read. It is of particular interest to medical men for the reason that its writer has seen much of the wounded and the vastly improved organization that has now been evolved to succour them without delay. "As one Tommy remarked, 'You 'ears the 'ell of a noise, and then the nurse says: "Sit hup and tike this broth"'—so speedy is the transit from battlefield to hospital.

⁹ *Vive la France*. By E. A. Powell. London: W. Heinemann 1916. (Cr. 8vo, pp. 268; illustrated. 3s. 6d. net.)

WAR WASTAGE AND THE BIRTH-RATE.

GERMANY AND GREAT BRITAIN.

In a recent report Dr. Newsholme has calculated that had the birth-rate of England and Wales been the same in 1914 as in 1876 there would have been 467,837 more infants born in 1914 than actually saw the light. In an official report to the Lower House of the Prussian Diet, on February 25th, it was stated that there were now 560,000 fewer births in Germany than would have occurred if the birth-rate of the year 1900 had been maintained. It was stated, further, that the decline of the birth-rate in Germany in twelve years had been as rapid as that in France in seventy, and that the number of births in Germany had sunk 75 per cent. more than the number of deaths.

The decline in the birth-rate has combined with the appalling wastage of the able-bodied male population in the war to make the maintenance of the population in the future a matter of frequent discussion in Germany. A society with the title *Deutsche Gesellschaft für Bevölkerungspolitik* has been founded by Professor Julius Wolf, who, in an address¹ at the first meeting, said that though the working classes were inclined to dread any interference with their mode of life, the increase of population after 1880 had coincided with enormous improvements in their condition; the lot of the working man in France with its low birth-rate was certainly not better than that of the German. He expounded what he called a "positive policy of population." Every effort should be made to encourage a will to marry and bring up a large family. The average age of marriage in Prussia was for men 29, and for women from 25 to 26.² Were marriages contracted earlier, not

¹ *Deut. med. Woch.*, November 4th, 1915.

² In England and Wales the mean ages at marriage in 1913 were bachelors 27.56, spinsters 25.72.

only would the birth-rate rise, but the incidence of venereal disease would fall. He advocated a reform in professional education which would enable a man to earn his living earlier, and to postpone some of his studies. Social problems, including housing and wages, were, he said, also closely connected with the birth-rate. The indirect taxation was burdensome to the working classes. Germany's fiscal policy penalized families with many children, and dealt lightly with bachelors and families with only one or two children. At present the third child in a family was an embarrassment, and the fourth a sorrow. The fact that the infant mortality was considerably greater in some places than in others showed that it was still capable of reduction, and young girls should be educated in domestic duties, and the will to marry and the will to propagate inculcated. Fräulein Müller, President of the Deutsch-evangelischen Frauenbund, promised the support of her society, but Herr D. Naumann, a Reichstag Deputy, was pessimistic as to the efficacy of the methods advocated. The relation of the housing problem to the birth-rate was, he said, obscure, districts with the best housing conditions sometimes showing the lowest birth-rate. The will to propagate, he added, was feeblest among Government officials, in spite of the fact that their economic future was secure. Dr. Hofmeier, speaking as a gynaecologist of more than twenty-five years' experience, said that the fall in the birth-rate was principally due to economic factors. He urged that the 180,000 illegitimate children born every year should not be neglected; for lack of care their death-rate was 25 to 30 per cent.

At a conference of the Zentralstelle für Volkswohlfahrt,² stock proposals, such as the special taxation of bachelors, were made, but Dr. Christian of Berlin suggested that the present system of monogamy for life might not meet future needs. He calculated that, were the birth-rate and death-rate of the German nation in 1912 to be maintained, the increase of the population within the next twenty years would be reduced only from 16.8 to 14 millions by the war. The deficit would be completely made good were the fecundity of the married to be maintained at the level of 1901 to 1910. Frau Fürth advocated extension of insurance, provision of subsidies, and the care of the unmarried mother. The suckling bonus, established soon after the outbreak of the war, should not be confined to the first twelve weeks, but should be given as long as the mother suckled her infant, up to eight or nine months. Celibacy among female officials should no longer be insisted on, and women engaged in professional duties should be encouraged to marry.

At this conference a school medical officer, Dr. Lewandowski, stated that the changes in the nation's diet caused by the war had reacted on school children's weight, which had not increased as much as in times of peace, but otherwise they had not suffered; the increased employment of women had, however, led to a corresponding neglect of young children. Frau Direktor Deutsch said that the German women had shown themselves admirably qualified for professional work during the war, but in household duties had not fulfilled all that was required; she suggested State schools for housewives and mothers in which the teaching would be adapted to the requirements of the various grades of society, and Fräulein Lange went so far as to suggest that domestic training for women should be made compulsory, as was military service for men.

As in this country, efforts have been made in Germany to diminish infantile mortality, but the results have not been conspicuously successful there. According to Dr. W. A. Brend, the infantile mortality-rate from 1901 to 1912 averaged 184 (exclusive of stillbirths). Mr. Benjamin Broadbent of Huddersfield, who speaks with special authority, seems to think that the reason for the comparative failure in Germany is that the schemes evolved there have savoured too much of the drill sergeant, and have not had sufficient regard to what in this country has from the first been looked upon as the fundamental doctrine—namely, that the mother, and the mother only, can properly tend the babe, and that the proper place for the mother and the babe is the home. We may, therefore, take comfort that we are working along right lines, and that expansion of the system of maternity and child welfare centres will result in a still further reduction in

the infantile death-rate. There was unfortunately last year an increase in the rate. The rate in England and Wales fell from 163 in 1899 to 95 in 1912 but rose again in the following year. In 1914 it was 105, and in 1915, 110. In Scotland in 1915 the infantile mortality-rate was 126, which is higher than in any year since 1901. It is 15 more than in 1914, 17 more than the mean of the five preceding years, and 14 more than the mean of the ten preceding years.

PREVENTIVE OBSTETRICS.

It is not yet, perhaps, as fully recognized as it ought to be that there is in obstetric practice a large sphere of preventive medicine which has hardly been entered upon. A great debt of gratitude is due to the pioneer work done at the Edinburgh Royal Maternity Hospital. The report by Dr. J. W. Ballantyne, published recently in the JOURNAL,⁴ shows that the hospital, by attracting dangerous complications of pregnancy, has helped to demonstrate the widely fatal effects upon the life of the child before birth—embryo or fetus—of morbid states of the expectant mother. No statistics have hitherto given any indication of the gravity of the facts, for there has been and is no means of gauging with any approach to accuracy the number of abortions which occur in this country as the result of maternal pathological conditions, and it is only recently that legislation has been sanctioned requiring the notification of stillbirths—that is, of pregnancies interrupted after the twenty-eighth week. Reference is not here made to criminal induction of abortion, but only to the miscarriages which take place as the result of one or other of the morbid states of the mother or of the contents of the uterus. There exists no means of making more than a guess at the frequency of such antenatal casualties, but the Edinburgh statistics justify the statement that the number of pregnancies ending as abortions, and therefore disastrously for the new life in the womb, is not small.

As an instance of the heavy loss of antenatal life to which reference is being made, the results of the prematernity work done at the Edinburgh hospital in the autumn quarter of 1912 may be taken. During the three months 36 women (7 unmarried and the rest married) were treated in the prematernity ward for one or other of the maladies of pregnancy; 2 of them were so completely relieved of their troubles that they were able to return to their homes, pregnancy continuing; 33 were delivered safely in the hospital; one girl suffering from acidosis of a grave type at the fourth month of pregnancy died. There was, therefore, one maternal death out of the 36 cases (not quite 3 per cent.), not a high mortality having regard to the nature of the cases. Three of the infants died after birth, and again it can be claimed that the post-natal death-rate was not high considering the diseases from which the mothers of the infants were suffering. But when the antenatal mortality is looked at a very different and a much less satisfactory state of matters is revealed: 17 of the infants were born alive and survived, and 17 died before they left the womb, whilst 3 (as already stated) died after birth. Out of 37 antenatal lives, therefore, 17, or nearly 46 per cent., were lost in the uterus. It is true that the gravity of the figures is to some extent lessened by the fact that one of the cases was a triplet abortion (counting as three antenatal deaths), and that there were 6 other abortions; thus 9 of the prenatal deaths were the result of miscarriage, for of course the embryos were not viable. Yet the deductions only serve to throw into clearer light the fact that miscarriages, whatever may be their effect upon maternal health and life, are most disastrous to antenatal life.

In this apparently gloomy fact, however, there lies hidden a hopeful one. Miscarriages are in many cases preventable, and it may turn out that one of the most beneficent parts of the work to be done by antenatal clinics and prematernity practice in the future may be the prevention of threatened or probable abortions. At the present stage it is not possible to discuss whether the child born as the result of a pregnancy in which a miscarriage threatened will be less fit physically and mentally to fight the battles of life; but, in the meantime, the prevention of antenatal deaths due to miscarriages is an object to be aimed at. There is at present a vast amount of maternal suffering in the period of expectancy among women of the

² Deut. med. Woch., November 11th, 18th, and 25th, 1915.

⁴ February 5th, 12th, and 19th, pp. 189, 234, and 275.

working class if the gestations be complicated by any of the many morbid states to which they are liable. The single fact mentioned in the report here quoted—that of thirty-one mothers suffering from albuminuria one only developed eclampsia—speaks strongly for the value of the work done.

Prevention is the keynote of the whole prematernity movement. At present it is not known how many lives are lost antenatally, and therefore how many might be saved cannot be stated; but there can be no doubt that many are so lost, and there is justification for the belief that by antenatal clinics and prematernity practice not a few of them may be saved. Infant life will be not less but much more valuable after the war, and the politician no less than the hygienist will be well advised to consider closely all available means of saving the unborn.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

THE NEW TAXES.

THE prohibition of the further importation of passenger-car chassis and parts has brought to an end the revenue planned by Mr. McKenna in his autumn Budget to be reaped as an additional war-time contribution from motoring. The sum received by the Exchequer while those duties were in force and the trade was free to import foreign cars and cycles amounted to £540,609. At this rate, had those duties remained in force for a full year, they would have amounted to a very appreciable sum more than the £800,000 which the Chancellor of the Exchequer hopes to reap from the alternative revenue from motoring through the new scale of licence fees. In face of the lapse of the duties through the prohibition of imports it was to be expected that motoring would in any case be taxed in an alternative way to yield some special war-time revenue.

The two obvious alternatives were increased licence fees or heavier petrol duties. There are many phases of the petrol situation which may not be made public, but which are quite appreciated by the Government. I am convinced, however, that had the Chancellor raised the duty on petrol instead of introducing heavier car licences, his proposals would have come in for a great deal more criticism from the motoring community than they are receiving now.

THE ALTERNATIVES.

The medical man who has not studied the matter in all its bearings may protest in all reasonableness that his car is as much a utility vehicle and as little a pleasure carriage as is the munition maker's motor-lorry, and he may ask why the whole of the burden of the new taxation is not placed on the shoulders of those who motor for pleasure and of whom there has been so much talk of late. The answer is that the data collected by the various motoring organizations from every quarter of the kingdom reveals that only a negligible quantity of passenger cars out of the total in use in the country are being employed for pleasure as distinct from one business purpose or another. Were the share of the revenue to be raised apportioned to this residue of pleasure car owners, the individual contribution would be so heavy that, practically without exception, the owners would be compelled to put their cars by, and therefore no money would be forthcoming for the Exchequer from this source. The question was whether the burden of taxation could be divided between the owners of passenger cars or whether some of the burden should be placed on the shoulders of the users of "utility" motor vehicles.

THE EFFECT OF THE HIGHER LICENCES ON VARIOUS TYPES OF CAR.

As far as this new taxation is concerned, at least 90 per cent. of medical men fall under the head of one of three groups. Let us consider each in turn, beginning with the least taxed classes as being those that probably constitute the greatest numbers.

First in the scale we have the light car users, such as Standard car, Swift, Singer, Stellite, and owners of such like vehicles, who will have to pay 3 guineas more licence fees for the full motoring year beginning January, 1917, and £2 7s. 3d., being three-quarters of the increased fee for the right to use their cars after August 15th next, because the new duties have been made law after only one quarter of the current year has lapsed.

Next we come to the class using such machines as 12-h.p. Rovers, and, indeed, anything up to the size of what is in point of accommodation a really big vehicle of great speed possibilities, such as the 16-h.p. Sunbeam. By the new scale of taxes those driving four-cylinder vehicles which do not exceed 80 mm. or 3½ in. cylinder bore will have to pay 3 guineas more for their motoring in 1916 if they want to employ their cars after August 15th next, and 4 guineas a year more for the full year beginning January, 1917.

In the case of those medical men who have cars that come within more than the third degree of taxation on the new scale, motoring would cost each 9 guineas more than he anticipated this year, and 12 guineas, or 5s. 3d. a week, more for the full year of 1917. This would be a material matter chiefly in the case of owners of Ford cars, some of whom, I gather, are suggesting that the whole system of Treasury rating should be altered, and the tax based, instead, on the original price of the car. While frankly admitting that some owners of such vehicles would feel the strain of an extra war levy of this sort, one has nevertheless to confess that it is to the interest of medical men as to all other sections of the community that no taxation system should be adopted that should prejudice the mechanical development of the motor. In what direction during recent years has the motor been evolved so that we are getting light, refined, and small power packets to do as much work and develop as good a turn of speed as large ones did formerly and with vastly more refinement? Briefly, by the development of a longer stroke in relation to bore. "Yes," the Ford owner may say, "I quite agree that, as regards British-made cars, or, for that matter, European ones, the present system of taxation is fair, but it is quite unfair to the American machine." That remark, however, is not quite accurate. If those American machines that constitute the newer models, and show that their makers have been making better motors of recent years, are studied it will be found that to get the efficiency, the refinement of working, the power from the engine volume, the flexibility, and so forth, there has been a gradual lengthening of stroke measurement in relation to bore.

Many of the 1916 American models come off quite well under this new Treasury rating. Take the car that is produced on the next largest scale to the Ford, the 12-h.p. 1916 Willys-Overland. Under the new scheme this machine is only taxed 4 guineas more for the whole year, because it is a new and modern design of engine. On the other hand, the Ford engine measurements have not varied since 1908. (See *Autocar*, November 7th, 1908.)

HOW THE MEDICAL MAN MAY BE RELIEVED.

In my opinion it would not be justifiable to alter the basis for arriving at amount of taxation unless it could be shown besides that by so doing the evolution of the motor would be encouraged. In the circumstances, far from encouraging development, it would be discouraged and a premium put on a type of motor which has contributed nothing to the world's knowledge of how to improve the liquid fuel internal combustion engine, while owners of other American manufactures, to say nothing of the British and European ones, the makers of which have been developing their motors from year to year, and the bore and stroke of whose machines do not remain in 1916 what they were seven and more years ago, would be penalized.

The medical man has to remember that, as an income-tax payer, his car charges are allowed to him as a business expense, and also that he has paid only half licence rates hitherto. If the duty had been put on petrol instead of on cars, even with the rebate allowed to medical men, those who would be paying respectively 3 and 4 guineas a year more for their motoring under the new licence scheme would not be as well off as they would be as matters now stand, while it is doubtful if those who will come within the 12 guineas extra tax will be much, if any, worse off. In any case it would not be good policy for the Treasury to upset the whole line of motor engineering development, which the New World itself is now copying from this country, merely to suit one particular class of machine; such a course would, moreover, have the effect of imposing additional burdens on the owners of dozens of other types of machines much used by the medical profession.

Therefore, in seeking a remedy for the case of the medical man, including owners of Ford cars or other machines of more than 16-h.p.—the British Medical Association has made representations on behalf of the profession to the Chancellor of the Exchequer this week—I suggest that his particular case could be served with least disturbance and most general satisfaction by making the extra duty only half what the ordinary member of the public will have to pay for any class according to Treasury rating. Thus, on a car of more than 16-h.p. the doctor would pay a war tax of only 6 guineas a year, or 2s. 7½d. a week, against the public paying 12 guineas, or 5s. 3d. a week. The policy, moreover, would be akin to the treatment of the profession in the matter of existing licences, also to the granting of a rebate on petrol duty to the medical profession. Thus no medical man would pay a total fee of more than 9 guineas a year for the use of any car suitable and necessary for doctors' work, and two-thirds of that tax is only a war-time levy. Suppose it obtains for two years, the Ford would still provide very cheap motoring for the profession.

MR. McKENNA'S CONCESSIONS.

As the foregoing goes to press, Mr. McKenna's reply in the House of Commons to Sir C. Kinloch-Cooke is announced, to the effect that the existing concession, under which registered medical practitioners pay only half rates on licences for motor cars and motor cycles, will be extended to the new duties. This, therefore, accords with the solution of the problem suggested above. In practice it means that the medical man will only have to pay a total of 3 guineas a year for the use of a light car; 4 guineas a year for the use of a machine not exceeding 16-h.p. Treasury rating; and of 9 guineas a year for a machine exceeding 16-h.p. Treasury rating; whereas the general member of the public will pay 6, 8, and 18 guineas in respect of those various classes of vehicles. The actual sums of money which doctors will have to disburse by way of extra duty this year are respectively £1 3s. 7½d. and one guinea and a half in mid-August for light cars and for machines not exceeding 16-h.p.; and in July £4 14s. 6d. for a machine of over 16-h.p. Treasury rating, for which the public will pay 9 guineas. Medical men using motor bicycles as well as side-cars are treated in the same way. Considering the crisis through which the nation is passing, and the urgent need of raising revenue, Mr. McKenna is treating the medical profession with fairness and understanding.

THE FUEL PROBLEM.

Far more serious for the medical man, as for the rest of the motoring community, is the petrol situation, if only for the reason that, whereas financial obligations in relation to licence fees are foreknown, in the matter of petrol prices none of us know where we stand from one week to another. The Government is striving to the utmost of its power to relieve the situation by imposing no more duties on motor fuel, which is rightly deemed to cost the community too dear already. It goes further, for the new scale of licence taxes very distinctly discourages the use of large-engined cars of the character that are greedy of motor fuel. When an owner has to pay £126 a year for the mere right to take his car out of the garage the Government is going about as near to prohibition of a particular class of motoring as any one can reasonably expect.

All the talk of the Government taking control of the petrol companies and compelling them to supply the public at fixed rates is utter absurdity, for the simple reason that if it fixed rates, still without incurring loss, it could not supply the public at cheaper rates than they are paying for their petrol now. Reduced to plain terms, petrol is worth just as much as it will fetch in the world's markets, and, as we are dependent on Transatlantic markets for the bulk of the supplies used by the public, we must pay what that fuel will command there plus the cost of bringing and distributing it here. Since last this matter was touched on in these columns there has been another 2d. a gallon advance in the price of Pratt's and the majority of other brands, consequent on the rise in the wholesale price of motor fuel on the part of the various refiners in the New World from whom the Anglo-American and other companies here have to buy their supplies. Briefly, the reason of the rise is that expansion of the consumption of motor fuel in the United States will

demand 25 per cent. more fuel than the total produced in the last year, of which total not more than 20 per cent. was exported, so that there is a threatened shortage of 5 per cent. for this year's requirements in America unless extra sources of supply are developed. Such resources are being developed, but gain under this head is offset by the facts that over one hundred American controlled oil wells in Mexico are at present idle owing to lack of transport facilities, that there is a blockage of shipping in the Panama Canal which is hampering the Rockefeller group in their dealings with the East, and that the production of the Cushing oilfield in the States has fallen off from 300,000 to 100,000 barrels a day of crude oil of the highest petrol content; besides which, for the time being, alternative fuels cannot be placed on the market of the New World by reason of the fact that the Steel Corporation and suchlike enterprises, which installed plant for producing benzole to compete with petrol when the price of the latter was only 20 cents an American gallon, are disposing of all their output of benzole now at between 80 and 90 cents an American gallon to the dye industries and to the makers of explosives.

DR. RITTMAN'S PROPHECY.

Dr. W. F. Rittman, inventor of the process which is claimed to yield anything up to 200 per cent. more petrol than the older methods of distilling petrol from the crude oil, and whose process the U.S.A. Government allows oil refiners within the borders of the States to use gratis, though only ten of them have adopted it so far, the Rockefeller group having a system of their own which apparently yields at least equally satisfactory results in practice, holds that either some way must be devised of increasing the available supply of petrol to meet the increased demand, or we must come to the use of fuels which have somewhat the same composition as the conventional motor spirit but which are more plentiful, or, finally, that we shall have to look to some other agent for use in the propulsion of motor cars and the operation of other hydrocarbon burning machines.

No two crude oils are the same. Of two wells in one oilfield one will yield more petrol than another. The average motor spirit content of petroleum in America is below 12 per cent. By new cracking processes Dr. Rittman holds that this can in time be brought up to 60 per cent. He says, however, that Californian and Mexican oils contain virtually no "gasoline," but can be made to do so by his fractional distillation process. He says that to-day 300,000 of the 2½ million motor vehicles that are owned in the States are being run on "cracked gasoline," otherwise motor spirit produced from kerosene, gas-oil, and so forth. He predicts that the rise in prices will continue uninterrupted until the middle of July next, will come down in mid-October to what it is to-day at wholesale in America, and will continue that rate of decline uninterruptedly until it comes back to normal.

That, however, does not solve the problem for this country, because it is largely a transport and distributing difficulty, which will obtain until the end of the war.

The patriotism of the Asiatic Petroleum Company, vendors of Shell spirit and other brands, in refusing to raise the price of their petrol to the public at a period when, commercially and morally, they would be thoroughly entitled to do so, cannot be overpraised. But as, owing to the enormously expanded employment of utility motor vehicles the demand for petrol among the civilian community in these islands is greater than it was before the war, and as owing to its contracts with the Government for the supply of the Services the Asiatic Petroleum Company can only let its clients have one-third of their normal requirements before all this expansion took place, it follows that that quantity of spirit is not much more than a bucketful towards a bathful that is needed. Therefore, by far the majority of motorists have no option but to buy the dearer brands, the first grades of which now cost 2s. 8d. a gallon in this country and 2s. 9d. a gallon in Scotland and Ireland. Indeed, during the next few months motor fuel costs are likely to prove a greater burden to the majority of the medical profession than the new scale of car licence fees.

The freeing of transport after the war, and the throwing open of oil wells in various parts of the world that are at present idle, or the production of which cannot be brought to market, will, of course, be the main solution.

MILITARY ORTHOPAEDICS.

LIEUTENANT-COLONEL ROBERT JONES, R.A.M.C.(T.), has been appointed by the War Office Inspector of Military Orthopaedics. Lieutenant-Colonel Jones is lecturer on orthopaedic surgery in the University of Liverpool, and has been surgeon to the military orthopaedic centre at Alder Hey Military Hospital, near Liverpool, since its establishment. He is also a member of the staff of the hospital at Roehampton, near Richmond Park, for men who have lost a limb in the war.

HOSPITALS FOR MEN WHO HAVE LOST LIMBS.

It is perhaps necessary to recall that the hospital at Roehampton—the Queen Mary Auxiliary Hospital—which was established about a year ago, with the approval of the War Office and Admiralty and with the co-operation of the Greenwich and Chelsea Commissioners, is a special hospital for men who have undergone amputation of a limb. Accommodation is provided for 300 men in two houses placed at the disposal of the committee by Mr. Kenneth Wilson. The men admitted to the hospital are retained there until the artificial limbs they need have been made and adjusted under the supervision of the experienced staff of orthopaedic surgeons attached to the hospital. A hospital on similar lines and with the same recognition from the War Office is being established in Glasgow, where, we understand, the same system of supervision and construction of artificial limbs on the spot will be followed. Mr. Hayes Fisher stated the other day in the House of Commons that cases of this class were being reported at the rate of 300 a month.

THE SCOPE OF MILITARY ORTHOPAEDIC HOSPITALS.

In addition to the men who have undergone amputation, there are among those returning from abroad to military hospitals at home a large number of cases of injuries of limbs, especially of joints, varying in severity, but all more or less interfering with the ability of the wounded man to do useful work in civil life. No one will doubt that these men can in a large number of cases be greatly benefited by skilled orthopaedic treatment, and it is obvious also that this treatment should be begun as early as possible. The recognition of this by the medical department of the War Office has led to the appointment of an Inspector of Military Orthopaedics, whose duty it will be to exercise general supervision on behalf of the War Office in respect of the treatment of orthopaedic cases in the various military hospitals and sections of hospitals set apart for them, and to arrange for the transfer of suitable cases to selected centres for orthopaedic treatment. The types of cases which will come within the scope of the scheme may be classified as follows:

1. Derangements and disabilities of joints, simple and grave, including ankylosis.
2. Malunited and ununited fractures.
3. Injuries to ligaments, muscles and tendons.
4. Cases requiring tendon transplantation or other measures for irreparable destruction of nerves.
5. Nerve injuries complicated by fractures or stiffness of joint.
6. Certain complicated gunshot injuries to joints.
7. Cases requiring surgical appliances.

It may also in many cases be thought well to refer to the special orthopaedic hospitals deformities and disabilities of feet, such as hallux rigidus, hallux valgus, hammer-toes, metatarsalgia, painful heels, and flat and claw feet.

The Hammersmith Military Orthopaedic Hospital.

The Hammersmith Military Hospital will be the first of these military orthopaedic hospitals to be organized under the supervision of the Inspector of Military Orthopaedics. The buildings consist of the Hammersmith Infirmary and Workhouse, and will hold a total of about 800 men. In addition to the ordinary surgical orthopaedic service, there will be departments for treatment by massage and mechano-therapeutics, for electrical treatment, and for radiant heat, whirlpool and other forms of baths, each in their own quarters. There will also be a large and well-fitted gymnasium. The workshops of the building are

large, and it is hoped to be able to fit them in such a way that all splints, surgical appliances, special boots and instruments, etc., may be made upon the premises. Special accommodation is to be made for plaster-of-Paris work, including the taking of plaster-of-Paris casts.

The staff of the hospital, apart from the administrative officers, will consist in the first place of four surgeons, a consulting neurologist, physicians in charge of the massage, electrical, and balneological departments, x-ray specialist, anaesthetist, gymnastic instructor, and four resident medical officers.

The British Red Cross Society has from the moment of its first suggestion offered its help to this hospital, and is assisting, both financially and through its organization, in providing the equipment required, which is necessarily elaborate.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held in March, twenty-six cases were considered, and £207 granted to twenty of the applicants. The following is a summary of the cases relieved:

Widow, aged 46, of M.R.C.P.Irel. who practised at Norwich and died in January, 1916. Applicant left totally unprovided for with four children aged 5 to 19. The eldest has joined the army and the youngest are at school. Applicant's health is bad, and she has no friends. Voted an immediate grant of £5 pending further inquiries.

Daughter, aged 44, of M.D.Edin. who practised at Leamington and died in 1884. Applicant along with her mother managed with the aid of the Fund to get along by letting some of their rooms. The mother died recently, and the applicant was unable to manage without a little help. Voted £6.

Widow, aged 68, of M.B.Edin. who practised at Bolton and died in 1905. Applicant lost about £700 through a defaulting trustee, since dead, and her only certain income is £10 per year. One daughter, a shop assistant, lives at home, and helps as much as she can. Voted £12 in twelve instalments.

Widow, aged 62, of L.R.C.P.Irel. who practised in North London, and died in February, 1916. Her late husband was a pensioner both of the Fund and Epsom College. Applicant has no income, and at her age expects it will be difficult to find work. Voted £12 in twelve instalments, and referred to the Guild.

Widow, aged 61, of L.R.C.P.Irel. who practised at Mitcham and died in 1914, after a long illness during which all his savings were spent. Applicant is now practically dependent on the hospitality of friends. Relieved three times, £40. Voted £10.

Wife, aged 37, of M.R.C.S.Eng., is in an advanced state of tuberculosis, and her husband is in an asylum. There are three children; the eldest is being cared for by a relative, the second is in an orphanage, and the youngest living with her mother. Relieved once, £18. Voted £18 in twelve instalments, and referred to the Guild.

Daughter, aged 39, of L.R.C.P.Irel. who practised at Earlsfield and died in 1902. Applicant is blind, and is training as a masseuse. Prior to the recent death of her mother, who had a pension for life, they managed. The applicant is now dependent on a relative who has to earn her living. Help wanted for tuition fees. Voted £10.

Daughter, aged 66, of M.R.C.S.Eng. who practised at Plymouth and died in 1879. Applicant has recently lost £30 per annum through the death of a friend. Only certain income £11 per year. Lives with sister, who receives an annuity from the fund. Relieved three times, £36. Voted £12 in twelve instalments.

Daughter, aged 55, of M.R.C.S.Eng. who practised at Manchester and died in 1898. Applicant managed to earn her own living, until an attack of nervous debility a few years ago necessitated her giving up her work. Only income a pension from her late employer of 6s. per week. Relieved twice, £24. Voted £12 in twelve instalments.

Daughter, aged 49, of M.D.Glas. who practised in Derbyshire and died in 1872. Applicant was left totally unprovided for, and has tried to earn a living by taking in paying guests, but owing to the war has not been successful of late. Relieved once, £10. Voted £10 in two instalments.

Widow, aged 61, of L.R.C.P.Irel. who practised at Dumfries and died in 1908. Was left unprovided for with four children, none of whom are able to help. Only income a pension of £12 per annum from another society. Relieved seven times, £68. Voted £12 in twelve instalments.

Widow, aged 58, of M.D.Edin. who practised in Cumberland and died in 1903. Left totally unprovided for, and tries to earn a living by taking in boarders, but owing to her residence being on the East Coast has been unsuccessful since the war. Has four children, all married, and unable to help. Relieved ten times, £112. Voted £12 in twelve instalments.

Daughter, aged 52, of M.R.C.S.Eng. who practised in London and died in 1895. Owing to exceedingly bad health applicant is unable to take permanent employment. Only income, £28 per year. Relieved four times, £51. Voted £12 in twelve instalments.

(To be continued.)

British Medical Journal.

SATURDAY, APRIL 15TH, 1916.

THE MAN WITH THE MUCK-RAKE.

In the second part of *The Pilgrim's Progress* Bunyan describes how Christiana was shown a number of instructive sights in the significant rooms of the House of the Interpreter. Among these was "a room where was a man that could look no way but downwards, with a muck-rake in his hand. There stood also one over his head with a celestial crown in his hand, and proffered him that crown for his muck-rake; but the man did neither look up, nor regard, but raked to himself the straws, the small sticks, and dust of the floor."

In the recent debate in the House of Commons, dealing with the army medical organization and its alleged defects in France and elsewhere, Mr. McNeill brought forth a great collection that had been made for him of the sins of omission and commission attributed to those responsible for our medical arrangements overseas. On this occasion the wounded were left lying all night in the open; on that occasion the supply of stretchers was caused to fall lamentably short; on other occasions there had been wholesale terrible breakdowns of the medical arrangements; indeed, the entire present organization of the Army Medical Service was fundamentally unsound, and the topic was embroidered by the speaker with all the worn fal-lals and fripperies of hearsay that any scandal-monger might collect for the adornment of a scarecrow in which he was interested. Many of the officers Mr. McNeill attacked, by name or otherwise, were on service abroad, and in any case are precluded by regulations from making any reply. Their defence in the House of Commons was undertaken by Colonel Arthur Lee, parliamentary secretary to the Ministry of Munitions, who had little difficulty in disposing of most of the allegations. Colonel Lee spoke with the authority of personal familiarity with the facts; for nine months he had been Lord Kitchener's special personal representative to report to him upon the practical working of the medical services in the field. He had had unique opportunities of watching the work of the medical services at many of the places where the breakdowns were said to have occurred, and he was in a position to say at once that Mr. McNeill's harrowing tales were not in agreement with the facts he had himself observed. Mr. Tennant has made his own opinion very clear on several occasions, and only last Wednesday he declined to entertain a suggestion by Mr. McNeill to appoint a roving committee to examine into the organization and working of the Army Medical Service at home. He would not, he said, undertake action which could only have the effect of dislocating and perhaps disorganizing a most efficient piece of mechanism. In so speaking the Under-Secretary no doubt expressed also the opinion of the Secretary of State, Lord Kitchener.

Some tales and anonymous statements there are that have not been authoritatively disposed of as yet. There is the matter of the redistribution of the stretchers said to have been collected together before the battle of Loos; what if it should prove to be the case that these stretchers were directed to be returned

to a central post, so as to be immediately accessible to all the divisions that might well have urgent occasion to use them? Would it have been advisable on the eve of an attack to strip several exposed divisions bare in order that one might have an unlimited supply? Again, with regard to the alleged neglect to call together the Army Medical Advisory Board to co-operate in the general superintendence of the organization of the medical service, what if it should prove to be the fact that most of the members of this Board have long been serving in an advisory capacity abroad? These are considerations that will occur to any one without any special knowledge of the facts; yet there is a tendency to discount such explanations and to accept as gospel any lurid and pessimistic account of the doings of our national services abroad. People are too ready to believe in the truth of any allegations of wholesale incompetence, or worse, made at the expense of the officers responsible for the conduct of our medical and military affairs in France, Flanders, the Mediterranean, or elsewhere. Many, like Mr. McNeill and his informants, are unduly eager to take on trust and repeat what they are told about such things, oblivious of the fundamental principle laid down once and for ever by Stareleigh, J., to the effect that what the soldier or any other man said is not evidence. The evidence is all the other way, and shows that the Army Medical Service abroad has done its work as well as is humanly possible, and has adapted itself to the varying needs of plague, pestilence, battle, murder, and the other weapons of offence used by the Central Powers with the greatest self-devotion and skill, and, what is more, with striking success. Some instances of local failure of its provisions there must have been; how could it be otherwise on a field of battle extending into three continents? But these instances will, we are firmly convinced, prove to be the rare exceptions and not the rule, as our ill-informed pessimists and grumblers, in Parliament and out, would have us believe.

But the medical tittle-tattlers have not been satisfied with trying to discredit the army medical arrangements abroad. There has been a dead set against the heads of the Army Medical Service at home, and at least one leading newspaper announced that Sir Alfred Keogh had been driven to resign. This particular insinuation was officially stated by the War Office to be "quite untrue," and the contradiction caused universal satisfaction. Sir Alfred Keogh, who very early in the war was called away from an honourable and interesting post to act as Director-General at home so that Sir Arthur Sloggett might be free to take over the direction of the medical service of the British Expeditionary Force in France, has accomplished something little short of a miracle. He has organized at home the medical service of a force ten times as numerous as the "contemptible little British army" of August, 1914. He had to accept the responsibility for the health of a multitude of raw recruits drawn from every class, unaccustomed for the most part to outdoor life or the hard work of soldiering; he had to organize a medical service to look after them out of the civilian medical profession who were ready and willing, and medically highly competent, but for the most part untrained in handling large bodies of men under military conditions. He has succeeded in organizing the medical work for the recruits, while at the same time meeting every demand from the army in France, in the Mediterranean, and now in Mesopotamia. He could not have succeeded without the loyal support of his profession. He has had it, but he would not have

had it if he had not deserved it. The good sense of the true heart of the medical profession has brushed aside the carping criticisms of backbiters; it has seen defects, but it has seen readiness to remedy them, to try all things, and hold fast that which is good. In the immense effort which Great Britain has made to become a great military power Sir Alfred Keogh is one of the outstanding figures. No man is indispensable and the Army Medical Service has many able officers, but as long as Sir Alfred Keogh feels able to stick to his post his profession want him there.

The man with the muck-rake, no doubt, serves a useful purpose at times, as did the drunken Helot in his day; we are glad to know that his investigation of the doings of the Army Medical Service has brought to light nothing more than what Colonel Lee happily described as a *nidus equinus*, a mare's nest constructed, no doubt, of the straws, the small sticks, and the dust of the floor detailed by John Bunyan. In conclusion, one may advantageously quote this author further: "Then said Christiana, Oh, deliver me from this muck-rake!" And so say all of us.

THE FOURTH WAR BUDGET.

WAR finance has hitherto necessitated half-yearly Budgets, and the Chancellor in his recent speech made it clear that a second Finance Act for 1916-17 was already regarded as inevitable. It is therefore natural that the taxpayer should look upon the present proposals with rather more apprehension than if his contributions to the Exchequer for the current year were thereby definitely fixed. It is a remarkable proof of the readiness of the country to bear the pecuniary burdens of the war that, although there is not any likelihood that the high-water mark of taxation for the year has been reached, the Budget has been received with all but universal approval, and such hostile criticism as has been heard is limited almost entirely to the more novel but less productive portions of the Chancellor's proposals.

Those taxes which are now embodied in the Finance (New Duties) Bill, such as the match tax, the railway travel tax, and the entertainment tax, are being attacked with some vigour, and with a not inconsiderable degree of plausibility, but at present it seems probable that in general they will hold good, though no doubt with minor modifications—as, for instance, with an exemption of railway season tickets from the new taxes. But Governments are frequently prepared to jettison unpopular taxes if by that means other and more lucrative portions of the financial cargo can be more easily saved; and it may be that the present attempt to "broaden the basis of taxation" may meet with less success than seems likely at the present moment. These new duties, as distinct from the increases in the old taxes, form only a small portion of the estimated yield of the whole, and it is clear that in any case by far the larger portion of the war taxation will be levied upon the upper and middle classes. The lowering of the exemption limit for income tax and the quarterly collection of the duties from wage earners was provided for in the second Finance Act of 1915, but is only now on the point of coming into operation, and it will not be possible to ascertain the financial result with any degree of accuracy for some time to come. For that reason, as well as on account of the administrative difficulties and expense, it would seem that any further reduction of the exemption limit is at present unlikely, though the political and economic advantages of such a course are generally admitted.

Coming to a consideration of the actual proposals,

it has to be borne in mind that the income tax rates laid down in the last Finance Act never came into full force. That Act provided for an increase of 40 per cent. on the then existing rates, with a relieving clause restricting the rise for 1915-16 to 20 per cent. only. Consequently the minimum and maximum rates for that year were 1s. 9½d. and 3s. respectively, and are now raised to 2s. 3d. and 5s., and the corresponding increases are therefore 5½d. and 2s., and not 1½d. and 1s. 6d., as several of the daily papers originally suggested. One example will serve to show the effect of the gradual rise in the rates: On an income of £1,000, half earned and half unearned, the tax payable at pre-war rates would have been £48; the effect of the various Acts has been to raise that contribution to £67 for 1914-15, to £120 for 1915-16, and to £162 10s. for 1916-17, but the last word in respect of this year's tax has probably not yet been spoken. How far income tax can be paid at the proposed rates without trenching on capital is a question that only future investigation can decide; certainly it cannot be done without severe personal sacrifice.

The most interesting feature of the income-tax rates as they will now be applied is the extended graduation of the "unearned income" rates. All tax paid by way of deduction at the source will apparently be at the full rate of 5s. in the £, and a very large number of taxpayers will for the first time find it necessary to prepare statements of total income in order to obtain the relief to which they will be entitled. Taxation at the source—alternatively referred to as the "sheet anchor" or the "fetish" of our income-tax system—has obvious advantages from the Revenue standpoint, and will no doubt be given up only with great reluctance, but the legislation of recent years, by requiring practically every person to render declarations of total income, has to a considerable extent weakened the arguments for its retention. When the promised revision and simplification of the tax is carried out, we may, perhaps, see this principle discarded in favour of a system under which each person would render a statement of his income and be taxed thereon on one charge, payable in instalments. Such a method of assessment is now being put into force in France, our Allies having adopted a system of logical simplicity more consonant with the genius of the French nation than the cumbrous edifice which has been laid on the foundation of the British readiness to accept a compromise as necessarily containing the best of both alternatives.

One advantage of the French system is that it is more flexible in the matter of allowances, as exhibited, for instance, in the deduction it makes for wives and dependants, as well as for children. In the case of our own system the only parallel allowance is in respect of children, which is fixed at £25 (comparing unfavourably with the more generous 1,000 francs in the French system), and which, unlike the French equivalent, is limited to persons whose total income does not exceed £500. This restriction seems to us no longer defensible, either in theory or from an administrative point of view. To-day all classes of society realize the importance of education more than ever before, and as the rates of tax have been so closely graduated, it would seem only reasonable that the relief should be extended and graduated on similar lines. So far as the practical difficulty of granting such relief is concerned, we suggest that it is being solved automatically, as more and more taxpayers are brought by extended graduation into contact with the Revenue officials in connexion with their own payments or repayments.

General practitioners must regard with some dismay the further increase in locomotion costs, which will be caused by the rise in the rates of licence duties on motor cars. The medical profession is in a peculiar position in this matter, and the British Medical Association made representations to the Chancellor asking for exceptional treatment of medical motorists in respect of the car and cycle duty. In view of the fact that the profession has already suffered hardship through the previous increase in these duties and also in the petrol tax, we are glad that the representations have met with a considerable measure of success. In two other cases of hardship, namely, that occurring through the double taxation of colonial incomes and of the application of the new rates to officers in the army and navy, the Chancellor announced that he proposed to leave these "vexed questions" where they stand now, and we suggest that the course adopted in those cases might with at least equal justice be followed in connexion with the increased licences so far as medical practitioners are concerned. Motor taxes have undeniably a flavour of the sumptuary law about them, at any rate in the popular mind, and so far as motor-ing may be for pleasure, few would be at pains to dispute the argument. But such reasons have clearly no application to the motor car kept by a practitioner to enable him to reach his patients with the minimum of delay, and any alteration in the tax payable in such cases should be rather in the direction of further relief than in that of increased taxation.

The medical profession has been met to a certain extent in this matter, and we are thus able to endorse the general opinion that on the whole the taxes imposed are as fairly distributed as possible, and that the Chancellor is to be congratulated on an exhibition of his own courage, of the sanity of his advisers, and of the self-sacrificing spirit of the whole nation.

PSEUDO-DARWINISM AND WAR.

OF all the misunderstandings and misrepresentations to which genius has ever been subject, perhaps those concerning Darwin have been the most tragic, at any rate, in their results for his own country and for the world at large. They afford a striking example of the danger pertaining to the coining of phrases which seem to sum up in a few words the discoveries of a lifetime but too readily catch popular imagination and lead it astray. In the opening paragraph of his discussion of the "struggle for existence"¹ Darwin carefully emphasized the point that he used the phrase "in a large and metaphorical sense, including dependence of one being upon another, and including (which is more important) not only the life of the individual, but success in leaving progeny." This plain statement of a vital qualification has been almost universally ignored by popular exponents or critics of the Darwinian hypothesis, who have stubbornly adhered to a narrow and literal interpretation of the term in question as well as of those others—"natural selection" and "survival of the fittest"—in which the great naturalist loosely summarized his main conclusions. In Germany the prestige and influence of Darwin have been great, but he has been fatally misunderstood. The sanction of his great name has been abused in the dissemination of heresies from which he himself would have recoiled in horror and contempt. In this respect, while Nietzsche and von Treitschke have not been guiltless, the most blatant sinner has been General Bernhardt, who in his widely read books assumed the authority of Darwin for his qualification of war as a "biological necessity" and the basis of all healthy development. It so happens that Darwin, as Sir James Crichton-Browne points out

in a recently published address,² explicitly condemned human warfare as dysgenic and pathological. On the face of it a nation is not a species, and, as Sir Ray Lankester neatly puts it, "You do not see fir trees advancing against beech trees, bears against wolves, vultures against eagles," in big well-drilled battalions and brigades. Sir James Crichton-Browne's address deserves careful study, not only for its crushing refutation of Bernhardt's fallacies, but for its interesting suggestion of extended importance for the factor of mutation in the cosmic process. Postulating a teleological origin and guidance of evolutionary changes, the author identifies as "four tremendous mutations, discontinuous, inexplicable by any naturalistic theory," and "revealing directivity," the transitions (1) from the physical to the vital, (2) from the vital to the mental, (3) from the mental to the moral, and (4) from the moral to the religious or spiritual spheres of action. On the vexed question of the relation of brain and mind, Sir James favours the transmissive theory rather than that which regards thought as the product of cerebration. "So far," he says, "are we from having parallelism between mental and physical states that it would be more correct to represent them as two immense and independent spheres which to a small extent impinge upon and intersect each other."

HORRORS OF A GERMAN PRISON CAMP.

IN THE BRITISH MEDICAL JOURNAL of March 18th, p. 421, reference was made to the experiences of Dr. François Léonetti during an epidemic of typhus in the prison camp at Langensalza in the early part of 1915. A still more damning record of German brutality is to be found in a report just issued by the Foreign Office of a Government Committee of which Mr. Justice Younger was chairman, on the camp at Wittenberg during the epidemic of typhus which raged there in the first six months of last year. The report is based upon information supplied by Major Priestley and Captains Vidal and Lauder, R.A.M.C., and other prisoners recently released. On the outbreak of the epidemic the German staff, military and medical, hastily fled, and six British doctors, Major Fry, Major Priestley, and Captains Sutcliffe, Field, Vidal, and Lauder, who had been detained at Halle in defiance of the Geneva Convention, were sent to Wittenberg. They found the conditions in the compounds almost indescribably horrible. The sick were practically left to their fate without attendance, medicine, or dressings. As a consequence of this neglect several cases of gangrene of the feet occurred, and one man had to undergo amputation of both legs. The only precautions taken by the Germans were to prevent the spread of the epidemic to themselves by isolating the prisoners from the outside world. There were between 250 and 300 cases among the British prisoners, of whom 60 died. The mortality among the French and Russians was much greater. The medical officers and the nursing orderlies suffered most. Major Fry and Captains Sutcliffe and Field died of the disease. The Committee has no doubt that "the conditions to which the camp authorities had reduced the camp and the prisoners they had abandoned was directly responsible for the deaths of these devoted men." Captain Lauder fell ill on March 7th, but recovered; when convalescent he resumed duty. The report pays a glowing tribute to the work of the English doctors and orderlies. Only once during the whole course of the epidemic did Dr. Aschenbach, the German medical officer in charge, enter the hospital or even the camp, and that visit was of the most perfunctory kind. His callousness is illustrated by an incident related by Captain Lauder. Shortly after their arrival at the camp Major Fry asked him for some medical requisite that was urgently needed.

² Bernhardt and Creation: A New Theory of Evolution. By Sir James Crichton-Browne, M.D., D.Sc., LL.D., F.R.S. Glasgow: James Maclehose and Sons. 1916. (Cr. 8vo, pp. 72. 1s. net.)

¹ The Origin of Species, Chapter III.

Dr. Aschenbach, who was cautiously standing outside the entanglements, refused the request and turned away with the words, "Schweine Engländer." And this is the man whom his Sovereign delights to honour with an Iron Cross! Perhaps it has been fittingly bestowed, for this "decoration," which used to be a badge of honour, has, since its wholesale conferment on baby slayers, become a symbol of infamy. The conditions of the Wittenberg camp are said to have improved, largely owing to the representations of Mr. Gerard, the American Ambassador, and measures have been taken to prevent a recurrence of the epidemic. The commandant has been removed, but Dr. Aschenbach remains in charge, and as long as he is left in authority we can feel no assurance that sick prisoners will be treated with any regard to humanity. Perhaps, like the commandant at the Cassel camp, he feels that he is making war in his own way by letting the prisoners die. The report has sent a thrill of horror through this country, and we welcome Lord Robert Cecil's announcement that steps are being taken "to bring to the notice of all civilized States these shocking revelations of cowardice and brutality."

WAR SURGERY, OLD AND NEW.

In an address delivered before the Philadelphia County Medical Society Dr. William W. Keen, Emeritus Professor of Surgery in Jefferson Medical College, gave an interesting account of the surgery of the American civil war in which he did notable service. Dressings then consisted of simple ointments, often only cold unboiled water, followed later by constant poulticing to produce an abundant flow of pus. The supply of ether and chloroform was plentiful. The hypodermic syringe was not in general use even towards the end of the civil war. For the examination of wounds surgeons had only the ordinary probe, which, being unsterilized, was often a means of introducing bacilli, as well as detecting bullets. Surgeons were in blissful ignorance of the fact that the sponges they used harboured multitudes of germs which infected every wound they touched. "If one fell on the floor it was squeezed two or three times in ordinary water and used at once." With knives, saws, forceps, and needles, these appliances made up the whole armamentarium of the surgeon in the civil war. The haemostatic forceps was unknown; each artery was caught and held up with a tenaculum and tied with undisinfected silk. Meantime other arteries continued to spout blood until they could be tied one by one. Secondary haemorrhage was common. Keen was called to five cases in one night after the battle of Gettysburg. In all the years since 1876, when he adopted Lister's antiseptic method, he has not seen five other cases of this occurrence. The Red Cross, the trained nurse, and the motor ambulance—which have all come into existence since the civil war—have rendered inestimable service, but the greatest advance has been the discovery of the part played by sepsis. More than once Dr. Keen saw his teacher, the famous S. D. Gross, "give a last fine touch to his knife on his boot—even on the sole, and then at once use it from the first cut to the last." When threading a needle, all pointed the silk by wetting it with germ-laden saliva and rolling it between germ-laden fingers. Practically every serious wound suppurated. Of over 2,800 cases of pyaemia during the civil war only seventy-one ended favourably; less than eleven in every hundred cases of lockjaw recovered; the mortality from trephining was 61 per cent. Dr. Keen says that he has never seen a case of hospital gangrene since the civil war. In the present war the danger of infection of wounds by the germs in a soil which has been under cultivation for centuries is increased by the conditions of trench warfare. But some of the worst scourges have been abated, and it is reasonable to hope for increasing success as knowledge grows. That military surgery is, in Dr. Keen's opinion, undergoing transformation is shown by the very title of

his address. He calls it "Old and New War Surgery," and it was delivered on March 24th, 1915. Already the "new" of a year ago has to a considerable extent become the "old." New conditions of warfare have brought new experiences which have led investigators to seek for new methods of treatment. These are on their trial, and are so recent that they are not mentioned by Dr. Keen.

THE CONTROL OF MALARIA.

A CONFERENCE, held in Sydney on January 21st to consider the best means of dealing with cases of malaria in soldiers arriving from New Guinea and other malarial regions in the Pacific, came to the conclusion (according to the *Medical Journal of Australia*) that anopheline mosquitoes are not sufficiently prevalent in the greater part of the Commonwealth to make the risk of the spread of the disease from returned soldiers a serious one. It was considered that the epidemic spread of malaria is improbable, except in Overland Corner in South Australia, and in those areas where the disease already exists. It was recommended that all discharged soldiers now in Australia who have been infected should be concentrated in one place in order to go through a course of treatment. The United States Public Health Service, as the result of an investigation as to the prevalence of malaria in the South, has found that in certain sections 40 per cent. of the inhabitants are infected. This estimate is based on 204,881 cases reported during 1914. The infection-rate among the white population was found to be more than 8 per cent., and among the coloured 20 per cent. A great reduction in the prevalence of the disease has been effected at thirty-four places in nearly every State in the South. In some the incidence was reduced from 15 per cent. in 1914 to less than 4 or 5 per cent. in 1915. Over 2,000 anopheline mosquitoes in malarious districts were dissected during the early spring months without a single infected insect being found; not until May 15th, 1915, was the first parasite in the body of a mosquito discovered. The Public Health Service therefore concludes that mosquitoes in the latitude of the Southern States do not ordinarily carry the infection through the winter. This discovery, it is held, indicates that protection may be secured by treating human carriers with quinine before the middle of May, thus preventing infection from chronic sufferers reaching mosquitoes and being transmitted by them to other persons. It is recognized that the eradication of the disease depends on the destruction of the breeding places of the mosquito, and a campaign with that object is recommended.

THE PSYCHOLOGY OF THE WOUNDED SOLDIER.

PROFESSOR FERRARI, director of the lunatic asylum of Imola, who has had opportunities of talking with hundreds of soldiers wounded in the battles on the Isonzo,¹ says that he was struck by the extreme modesty of the men, who were disinclined to speak of the time spent by them in the trenches or of what they had done there. Ferrari traces this reserve to a sense of honesty which makes them feel they are less worthy of admiration than their comrades who have given their lives. In the matter of projectiles the wounded soldier, he says, has some curious preferences. The ideal is the rifle bullet; next comes the hand grenade; then shrapnel; lastly, the airplane bomb. The last is despised because it is not necessary to be a soldier to be hit by it. The bullet has something personal about it as coming from an enemy who might himself have been shot by the wounded man; it is thus the symbol of a kind of duel with equal weapons, if not under the same conditions. Ferrari's observations go to show that the mental state of the soldier during the various phases of the campaign undergoes marked modifications. While he is waiting to be sent forward to the firing line an *esprit de corps* is developed which suppresses or attenuates individual

¹ *Policlinico (sezione pratica)*, November 18th.

character and brings all to a higher moral level. The honour of a man's birthplace, regiment, and branch of the service has to be maintained at whatever cost; nothing else counts. It is in the firing line, however, that the new spirit is chiefly formed. In the "hell" of the trenches the men are "transformed" by the feeling that a tremendous task has to be accomplished and by the disturbance of all the normal conditions of life—the narrow space in which they are confined and the cramped position in which they move and have their being. Very few admitted that they felt fear; the absolute concentration in the complex act to be done made them insensible to everything else, so that a quiet and peaceful man who till yesterday would not have raised his hand against any one, now from his trench seeks with careful deliberation to kill any enemy within range. Very few do this with any feeling of hatred—at least, Ferrari adds significantly, at first; it is rather a game of craft, the inborn instinct of the chase. The enthusiasm with which the order to attack is received is partly due to a feeling of relief at getting out of a hole where one is under shell fire to which no effective reply can be made. Men hit in such circumstances are stopped instantly, while all their faculties are at the highest tension; this sudden arrest gives rise to a psycho-physical state which manifests itself in a tendency to speak of the assault in which they took part as soon as they can and to take no interest in anything that does not relate to it. Together with this there is a desire to carry on the fight in order to settle accounts with the enemy.

WASSERMANN REACTION IN MILK.

K. K. MORDWINOW¹ has recently reported the results of a series of examinations of human milk for the Wassermann reaction. He states that his results are in agreement with those of Tomsen, Bate, and others, and show that the reaction with human milk gives quite satisfactory results. The specific antibodies reach the milk from the blood at a very early stage. Mordwinow has succeeded in getting a positive Wassermann reaction on the second day after delivery. The action persists during lactation; he obtained a positive reaction as late as fifteen months after delivery. Cases in which the milk gave a negative reaction and the blood a positive were rare; this condition was observed in one case only out of twenty. In three cases he had a stronger positive reaction with milk than with blood, and the infant also gave a positive reaction. He points out that the milk reaction may be of particular value in cases in which a wet-nurse refuses a blood examination.

TUNGSTEN AS A SOURCE OF ULTRA-VIOLET RAYS.

MORE than one form of open tungsten arc has already been used for obtaining ultra-violet radiation, but, although rich in the quality of its ray output, the sputtering character of the flame and the continual attention which it demands militate against its hospital use. The enclosed tungsten arc is a new lamp, recently introduced commercially, which incorporates a very ingenious method of striking the arc between a special filament and a small ball of tungsten; and to adapt it to this special purpose it has been constructed in a quartz bulb. The lamp gives a good ultra-violet spectrum, though not the very short wave lengths obtainable with the open arc. A paper on the use of the lamp for therapeutic purposes was read by Mr. B. H. Morphy and Mr. S. R. Mullard at the Röntgen Society on April 4th. It was urged that its greater convenience compensated for any disadvantage. If the lamp is overrun—thereby, of course, diminishing its life—the rays obtained extend much further into the ultra-violet region. In the course of the discussion Major Wilson, of the Canadian Medical Service, said that ultra-violet light was being used extensively in the base hospitals for the treatment of

wounds, and he had himself made some experiments with a view to getting ultra-violet radiation of much shorter wave-length than hitherto obtained by striking an arc in tungsten vapour.

We regret to record the death from pneumonia, on April 8th, of Mr. Arthur E. J. Barker, Professor of Surgery, University College, London, who has been serving as consulting surgeon to the Southern Command, with the rank of lieutenant-colonel.

Medical Notes in Parliament.

War.

The Number of Medical Officers in the Navy and Army.—In reply to questions by Mr. Aneurin Williams, the Secretary to the Admiralty stated, on April 6th, that the number of qualified medical men now employed in connexion with the navy was 1,118. This did not include part-time medical men—namely, Admiralty surgeons and agents. Mr. Tennant said, on April 10th, that there were 10,659 medical men holding commissions in the army at the present time. In reply to Sir J. Lonsdale, on April 12th, Mr. Tennant stated that medical men between the ages of 45 and 55 were being employed as commissioned officers for general service in the United Kingdom. Doctors over 55 might offer their services for local employment to the General Officer Commanding-in-Chief of the Command in which they were living, or in which they desired to do duty with troops. The policy should be that the medical men of more advanced years rendered the country the better service by undertaking the care of the civil population, and thus setting free those of military age who were physically fit for duty at home or abroad.

Territorial Medical Officers.—Mr. Lynch, on April 10th, asked whether there was any discontent amongst Territorial medical officers, especially those attached to regiments; and whether the appointment of a Territorial medical officer of position and long service as such on the staff of the Director-General at the War Office would be considered, and also the insertion in the *Army List* of a seniority list of the officers of the Territorial medical service. Mr. Tennant said: "The Territorial regimental medical officers joined the service for the specific purpose of doing the duties in which they are now engaged, and it is unlikely that they would be discontented if called upon in time of war to assume responsibilities for which they engaged in time of peace. Promotion of regimental medical officers is regulated by time service. Other Territorial Force medical officers are promoted by selection and seniority in their units. In these circumstances there is no need for a seniority list. The Director-General has an officer on his staff who has considerable experience of the Territorial Force." Mr. Lynch also asked whether a lieutenant-colonel of the Territorial medical service of many years' service received the same remuneration as a temporary lieutenant-colonel appointed since the commencement of the war; if so, whether this was in accordance with the spirit of the War Office undertaking that such officers should receive the pay of the corresponding rank as laid down by the Pay Warrant, 1914, for officers of the Royal Army Medical Corps; whether in the case of such officers their experience and their services were held to make them more valuable; and whether the higher rate of pay of 35s. laid down in the warrant for lieutenant-colonels of the Royal Army Medical Corps would be given them after five years' service in the ranks. Mr. Forster replied: Yes, sir; these officers are treated in accordance with the undertaking referred to. Unmobilized service in the Territorial Force cannot be held to count towards the higher rate of pay as if it were full-pay service in the regular army. If any Territorial Force lieutenant-colonels give the necessary amount of embodied service, they will be entitled to the higher rate of pay.

Army Medical Administration.—On April 12th Mr. R. McNeill asked the Under Secretary of State for War whether he would appoint an independent committee to examine into and report on the organization and working

¹ *Meditsinskoye Obozreniye*, 1915, N. 13-17.

of the Army Medical Service at home and abroad. Mr. Tennant replied that he could not undertake action which could only have the effect of dislocating and perhaps disorganizing a most efficient piece of mechanism.

Artificial Limbs.—Mr. W. Thorne, who, on April 6th, asked a question as to the supply of artificial limbs, suggested that the provision of such limbs and the payments for the maintenance of the men in hospital while the limbs were being supplied and fitted were inadequate, that voluntary subscriptions were being solicited, and that boards of guardians had passed resolutions to the effect that all such expenses should be a national charge. The Financial Secretary to the War Office said that artificial limbs were supplied in kind at Government expense, and the recipients fully maintained in hospital at public expense while they were being fitted. Nothing was known as to resolutions by boards of guardians to the effect mentioned.

Motor Operating Theatres.—On April 10th Mr. Lynch asked the Under Secretary of State for War for statistics of the number of cases of compound fracture in which life or limb had been sacrificed owing to sepsis; and whether, with a view of reducing the mortality, a system of motor operating theatres had been established at the front. Mr. Tennant replied that the War Office was not in possession of the statistics mentioned, and referred Mr. Lynch to answers given him on July 26th and February 29th. In the earlier answer (BRITISH MEDICAL JOURNAL, July 31st, 1915, p. 188) Mr. Tennant said that the question of sending motor operating theatres to the front had been carefully considered in communication with the expert advisers overseas, with the result that it had been decided not to send any motor operating theatres, as the opinion of the expert advisers on the spot was that their provision would not diminish the rate of mortality of abdominal wounds. The question put by Mr. Lynch on February 29th was as to whether, by the provision of movable hospitals, or by a closely connected series of hospitals within a short distance of the firing line, operations on the severely wounded might be undertaken with the least possible delay. Mr. Tennant said that use had been made of this description of hospital for many months, and in his answer on April 10th explained that he was referring to the casualty clearing stations, which are as near the firing line as is safe. These clearing stations, he added, are essentially mobile, as they accompany divisions in an advance.

Medical Examination of Recruits.—The question of giving facilities for the medical examination of men before they are actually called up was raised on April 10th by Captain Douglas Hall. Mr. Tennant said men might, if they so desired, be examined by a medical board previously to being called up for service, or, in order that they might have time to settle their affairs, ten days' leave might be given to them. Arrangements were being made for such an examination some time in advance. The War Office could not institute a larger number of medical boards than had already been formed, owing to the fact that there was not a sufficient number of skilled medical officers to carry them out. With regard to the special case of the Isle of Wight, the request of the local recruiting authorities had been approved for the carrying out of the preliminary medical examination of recruits by the medical officer at Parkhurst so long as he was a regular officer. All men had to go before the medical boards unless rejected at the preliminary examination at the recruiting office.

Soldiers and Sailors: Sanatorium Grants.—In reply to Sir Henry Craik, the Financial Secretary to the Treasury said, on April 11th, that it was proposed to entrust to the Statutory Committee on Soldiers' and Sailors' Pensions the duty of providing treatment in sanatoriums of tuberculous cases among soldiers and sailors. The normal practice was that the non-employed soldier or civilian was dealt with by the local authorities, but certain of them had no institution. Pending the establishment of the statutory committees, grants were made out of public funds, but in future the committees would undertake this work.

Invalid Prisoners in Switzerland.—Mr. Tennant stated, on April 11th, that the arrangements had been agreed to as to the internment of British and German invalid prisoners of war in Switzerland, on the principle that British and German prisoners should equally be interned in Switzerland, the one as it were in exchange for the other, though it was not really an exchange. The French Government had granted permission for the passage of German prisoners from the United Kingdom through their territory, and the necessary details for giving effect to the scheme were being worked out.

Health of Munition Workers.—In reply to Mr. Lewis Haslam, on April 10th, who asked questions as to whether the recommendations of the Health of Munition Workers Committee were being carried out, the Parliamentary Secretary to the Ministry of Munitions (Dr. Addison) said that the precautions with regard to ventilation and mechanical devices to ensure workers against poisonous fumes were being enforced by the inspectors of the Factory Department of the Home Office as a part of their general administration. Mr. Haslam also asked whether the Committee had reported that the health and efficiency of munition workers had been detrimentally affected by too prolonged hours of work, and had pointed out that continuous overtime not only tended to ruin the health of the worker of average powers of endurance, but also was excessively costly and prejudicial to economical and effective production; and, finally, whether compulsory powers were being taken to prevent the continuance of the evils indicated. Dr. Addison, in reply, stated that the exercise of compulsory powers had hitherto not been found necessary, and referred to a

written reply of Mr. Lloyd George on April 4th, in which he stated as follows: "The hours of work of women and young persons in controlled establishments, as in other factories and workshops, are limited by the Factory Acts and Regulations made by the Home Office thereunder, subject only to exceptions by general or special order of the Home Office under paragraph 150 of the Factory Act, 1901. The Ministry of Munitions are in constant and regular communication with the Home Office as to the extent to which and circumstances in which such orders of exemption should be granted with a view to giving effect to the recommendations of the Health of Munition Workers Committee. No special instructions regulating the hours of male adult workers have been issued by the Ministry of Munitions, but steps are being taken to reduce Sunday labour and to secure that adequate weekly rest periods are provided."

Motor Car and Cycle Licences.—On April 12th Mr. McKenna said, in reply to Sir C. Kinloch-Cooke, that the existing concession under which registered medical practitioners paid only half rates on licences for motor cars and motor cycles would extend to the new duties. In reply to a question, on April 6th, the Chancellor of the Exchequer said that it was not proposed to alter the date on which motor car licence duty would be payable, but a supplementary licence for the remainder of the current calendar year would have to be taken out before June 30th or August 15th for cars, etc., which it was proposed to use after these dates. The new duties would, like the existing duties, be collected by the local authorities on behalf of the Exchequer. In reply to a supplementary question, Mr. McKenna said that he imagined that if a car were not used the local authority would insist upon the surrender of the number of the car in order to prevent it being used. In reply to Mr. Rowlands, on April 10th, Mr. McKenna said that he was considering whether exemption from duty could not be granted for cars used exclusively by the owners at their own expense for Red Cross, special constabulary, Voluntary Aid Detachment, and other voluntary work for the Government.

Notification Fees.

The Local Government (Emergency Provisions) Bill was considered in Committee in the House of Commons on April 11th. On Clause 5, provisions as to notification of diseases, which proposed to reduce the fee to be paid to a medical practitioner for notification in respect of a case of infectious disease occurring in his private practice to 1s., Sir Philip Magnus moved an amendment to provide that the fee remain 2s. 6d. except in the case of measles. He said that the mere fact that this reduction had been recommended by the Retrenchment Committee did not seem to him, or to a large number of members of the medical profession, a sufficient reason for reducing the fee hitherto received. No class in the country had made greater sacrifices than members of the medical profession. A large number had given up incomes of considerable amount to join the R.A.M.C. for a very small salary for a long period, while other practitioners were doing work at hospitals for which they got practically nothing. Sir Philip Magnus referred to the deputation consisting of the Chairman of Representative Meetings, the Chairman of the Parliamentary Subcommittee of the Medico-Political Committee, and the Medical Secretary of the British Medical Association, to the Parliamentary Secretary of the Local Government Board on April 6th on the subject, and recalled Mr. Hayes Fisher's promise then given to confer with the President of the Local Government Board. Sir Philip Magnus asked what answer the President had given. Members of the medical profession, he said, regarded the statement made on the second reading of the bill, that the notification of diseases involved nothing more than clerical work, as a slur upon the manner in which they investigated these diseases before notification was made. A doctor was required to supply a diagnosis, and for such a certificate the fee of 1s., as compared with the 2s. 6d. hitherto paid, was not sufficient remuneration. The practice of economy where skilled professional opinion was required was very unwise. He believed that the whole amount of the saving would be very small. Measles might be distinguished from other infectious diseases on account of the greater ease with which it was diagnosed, and it was for this reason excepted in the amendment he had proposed. Mr. Hayes Fisher said that he desired to join in

The eulogy passed upon medical men for the splendid work they were doing, not only abroad, but at home, and he deeply regretted that any words he had used should have seemed to cast any slur upon the medical profession. He thought, however, that no words of his could be so interpreted. The proposed reduction did not originate with the Local Government Board, but with the Retrenchment Committee; it was that Committee which said that almost the whole of the work involved was clerical. For his own part he recognized that much more than clerical labour was involved. There must be, in the first place, a complete diagnosis, and he gave every credit to the doctors for doing their work fully and admirably. But the diagnosis had to be made for the patient, and the doctor could not know how to treat a patient until he had made the diagnosis. It was not until he had fully ascertained what the disease was that the Act called upon him to notify it. The filling up of a certificate was a simple form, and the Retrenchment Committee had come to the conclusion that for that *ls.* was sufficient, at all events, during the period of the war. No doubt the fact that the list of diseases to be notified was growing had been taken into account. The deputa- tion from the British Medical Association admitted that *ls.* would be sufficient for notifying measles, but urged that 2s. 6d. should be retained for all other diseases. Mr. Hayes Fisher said that he had consulted the President of the Local Government Board as to whether there was any ground for differentiating diseases. The departmental authorities consulted said that they could not draw any clear line of distinction between the medical responsibilities for notifying measles and any other infectious diseases. The medical advisers of the Board had also been consulted, and had said they could not differentiate between different diseases, and that if *ls.* was sufficient for the notification of measles, then *ls.* was sufficient for drawing up a simple form with regard to other diseases notified. He could not hold out any hope that the Government would forego the clause; it must be retained, and the doctors—at all events for the period of the war—would, he hoped, accept the *ls.* instead of 2s. 6d. Mr. J. Samuel made an appeal for a reconsideration of this decision, holding that the reduction was false economy. It must tend to produce very great discouragement among doctors, even though the reduction was made in war time. Mr. Boyton said that the statement by Mr. Hayes Fisher would be very unsatisfactory to the medical profession. The increase of work thrown upon the medical profession owing to recent legislation, the multiplication of forms and returns, had rendered their professional life onerous, and their labours constant and anxious. They were called upon to make many sorts of returns for the small fee of 2s. 6d., and it was not too much to give for such work. He could not understand the policy of the Local Government Board in reducing the fee, especially at a time when the medical profession was making greater sacrifice than any other body of people in the country. Sir Philip Magnus said it was much to be regretted that the opinion of the medical advisers of the Local Government Board should differ from that of the bulk of the medical profession, as expressed by the British Medical Association, and he hoped that the view expressed in the letter of that Association to the President of the Local Government Board would be accepted by him. He appealed to Mr. Hayes Fisher to consult the President once more and see whether some compromise could not be made which would be likely to satisfy the majority of the medical practitioners still left in the country. The amendment was negatived without a division. After a drafting amendment, moved by Mr. Hayes Fisher, had been accepted, Mr. Samuel, on the question that the clause as amended stand part of the bill, appealed for a reconsideration of the matter before the report stage. He considered that the Local Government Board had made a grave error. Sir Philip Magnus also appealed to Mr. Hayes Fisher to consult again with the President of the Local Government Board. Mr. Hayes Fisher said that he would report that there was a difference of opinion in this matter, but, judging by the view expressed by the President when he conversed with him on the subject not long ago, he could not hope that the President would change his mind. The clause was agreed to without a division, and, after further progress, the proceedings were postponed at the appointed hour.

Infantile Mortality.—The President of the Local Government Board gave the following information, in reply to a question by Mr. King, on April 5th: "The latest figures for 1915 show that the death-rate under 1 year of age amounted to 110 per 1,000 births, as compared with 115 per 1,000 births in the previous ten years and 105 in the year 1914 and 108 in the year 1913. In spite of the general restriction of local expenditure, active steps are being taken by practically all the larger local sanitary authorities to lessen infant mortality and to promote the welfare of infants generally. A large number of local authorities have appointed health visitors, who advise mothers as to the care of their infants; in most of the large towns maternity and child welfare centres have been established, at which expectant and nursing mothers receive medical advice and minor treatment, and in many places arrangements have been made for the provision of midwives and of doctors for the confinement of necessitous women and for other assistance for expectant and nursing mothers and children. My department have distributed a grant of about £41,000 in aid of maternity and child-welfare work during the financial year which has just ended."

Death Certificates.—In a written reply to Mr. King, on April 6th, the President of the Local Government Board said that he could not at present undertake to introduce legislation relating to the confidential certification of the cause of death as recommended in the report of the Royal Commission on Venereal Diseases.

Medical Treatment of School Children in Ireland.—In a written reply to Mr. V. Kennedy, on April 6th, the Chief Secretary for Ireland stated that the Commissioners of National Education had in June, 1914, prepared a scheme for the utilization of the grant towards the medical treatment of school children as apart from dental treatment, but the Treasury in August, 1914, had intimated that it could not approve the scheme. The total expenditure from the vote on this service between April 1st, 1912, when the grant was first made available, and March 31st, 1916, was £2,111, the whole being in respect of dental treatment. The grant was available towards meeting the cost of the medical treatment of school children and services ancillary thereto, and could be availed of only in respect of schemes approved by the Lord Lieutenant. Payment could not exceed one-half of the certified amount of the expenditure in the case of any scheme. The condition that one-half of the expenditure should be provided from local sources was prescribed by the Treasury when the grant was first placed on the Estimates.

Venereal Diseases: Examination of Prisoners.—In reply to Mr. King the Chief Secretary for Ireland said that, so far as the General Prisons Board for Ireland was concerned, no difficulty would be made in giving effect to the recommendation of the Royal Commission on Venereal Diseases that where the medical officer of a prison considers that an examination of a woman is necessary it should be made by a woman doctor. In the only prison that is wholly occupied by women prisoners in Ireland the medical officer is a woman.

German Scientists.—In reply to Captain Bathurst, on April 6th, the Prime Minister said that the Government had no power to intervene in cases of the retention in the list of members of the Royal Society and other learned societies in Great Britain of German scientists, including some who had been instrumental in concocting poison gases.

Paper.—In reply to Mr. Field, on April 5th, the President of the Board of Trade said that as at present advised he did not think it desirable for the Government or the Royal Commission on Paper to take possession of existing stocks, and trusted that no such action might prove to be necessary.

At the present time when new cars are hard to obtain, medical men, like other motorists who have to study economy, are looking for means to improve the running of existing cars which have been in use a few years, and would perhaps have been sold had new ones been obtainable. One of the most likely parts of an engine to wear and cause trouble is the carburettor that has moving parts of any kind, and as any wear affects the adjustment, the efficiency of the engine is reduced. It has been found by many motorists that a moderate sum spent on a new carburettor of good make has put several years on the life of the car, incidentally enhancing the price which could be obtained for it if the owner desires to sell. The carburettor of which we have heard most in this connexion is the Zenith, which has no moving parts that can wear, and is therefore particularly adapted for use on a car where reliability is of the first importance, as is the doctor's. Apart from any improved running we are informed that a considerable economy is effected in petrol consumption. In one instance which has been mentioned to us, the improvement was from sixteen to twenty-three miles to the gallon. At the present price of petrol such a result would lead to the carburettor paying for itself in a few months.

THE WAR.

THE ATTACK ON THE ARMY MEDICAL SERVICE.

An officer who has been with the British Expeditionary Force in France continuously, save for two or three periods of leave, since October, 1914, has written as follows in a private letter after reading the full report of Mr. McNeill's speech in the House of Commons on March 15th, and Colonel Lee's reply on March 16th:

On March 15th everything that it was thought could be said against the Army Medical Service and its chief administrators in Great Britain and France was voiced by one of the most experienced exponents of grievances that the House of Commons possesses. On March 16th the charges were met by Mr. Arthur Lee in a speech so crushing, that even so doughty a fighter as Mr. McNeill seems to have felt that he must throw up his brief. Incidentally he admitted that he had no first hand knowledge of matters, and threw the blame for his errors on those who instructed him.

Statements of this kind are usually written down as mere excuses, but in the present instance this would be unjust, because what was apparently said to Mr. McNeill and repeated by him is very much what has been said to a good many of us on many occasions. It is, in fact, a good many months ago that these attacks on the Army Medical Service began, and it has long been clear that there is a cave whose inhabitants are out to disturb as far as they possibly can the confidence of the public in the wisdom and ability of the administrators of the medical affairs of the army.

The cave has exhibited considerable cunning. Knowing that the public had too intimate and personal a knowledge of the way in which the wounded were being treated to be easily convinced that there could be anything much wrong the cave has avoided a frontal attack, and endeavoured to excite disquiet by dwelling on alleged slackness in matters of organization and other technical details. On such subjects neither the public nor the medical profession at large can be well informed. So for a time the cave had a little success, being assisted thereto by certain newspapers which one after the other open their columns to the grievances, which the writers failed to recognize were due not to the army system but to the inevitable circumstances of war.

But the success of the cave was not prolonged; its battle line began to look ragged a month or two ago, and when at length in March it ventured on its great push it was utterly defeated. Consequently the campaign is not one of which the cave has any reason to be proud, for it has certainly done no good, and probably has achieved some harm. Attacks of the kind almost invariably necessitate the preparation of returns and reports which would not otherwise be needed, and thus lessen the time available for attending to ordinary and really useful business. These attacks ought, therefore, to be resented both by the medical profession and the general public as *contra rem publicam*.

Never before have two men had to undertake a larger task or greater responsibilities than those that have been shouldered by Sir Arthur Sloggett and Sir Alfred Keogh respectively during the last eighteen months. They have had to deal with members of a profession accustomed both to think for itself and to express its opinions freely, and it was natural that various steps taken both at home and abroad should have been deemed open to criticism; it was almost equally natural but far less defensible that one man here and another there should have considered that had he been in charge of matters he could have managed things much better. But, nevertheless, the fact remains that a huge task has up to the present been most successfully accomplished. The health of the army has been maintained at a singularly high level, and the wounded have been tended both individually and collectively with tenderness and most enlightened care.

The medical public, in fact, owes the deepest gratitude to the officers in question. During the last eighteen months it has been upon its trial, and had it been less ably led it would have suffered greatly in public opinion, whatever sacrifices individuals might have made. As things are, it stands distinctly higher in public opinion than it did at the beginning of the war.

What have been the motives of the men who entered this cave? It is difficult to say. Doubtless they considered themselves to be acting altruistically, but it is not likely that anyone else will take that view. There are certain

individuals in this world who, having obtained a certain position, resent the idea of any large public affair being conducted without their assistance. There are others who are ever ready to pull down any existing pile in the hope that in the general ruin something valuable may roll in their direction. There are also nobodies who, confusing notoriety with fame, deem that they will become somebodies if they agitate long enough and loud enough.

Whether there will be any attempt to restart the campaign remains to be seen. But being aware of the methods the cave has hitherto employed, I suggest that anyone invited to assist them should closely question those by whom they are approached. If, for instance, statements are made to them on the alleged authority of B. or C. they should ascertain precisely what real knowledge of matters B. or C. possess. Both in France and in England the work is on so large a scale that it is scarcely possible for anyone not seated at the centre where all nerves meet to apprehend accurately any particular item of work. Moreover, in France the different units are so scattered, there is so much difference in their environment and the character of the work, and aims and general needs everywhere differ so greatly that only exceptionally fortunate individuals gain any real knowledge of it as a whole. An officer may work quite a long time in France and yet acquire nothing beyond hearsay knowledge of a very small part of the general work.

If the statements of men of really long experience are to be received with caution, those of individuals who after a few months abroad have preferred to return home to look after their personal interests should not be swallowed even with a pinch of salt.

THE CARE OF CRIPPLES IN GERMANY AND AUSTRIA.

A congress was held in Berlin early in February to discuss the care and education of crippled soldiers. An exhibition of artificial limbs and other devices for helping cripples to become self-supporting was also held. It was stated that in Austria this problem had been dealt with so drastically that it was impossible for a cripple to refuse treatment, and that in Hungary a special commission had been appointed, with powers to refuse pensions and every other compensation to cripples who would not be treated. Another speaker gave an account of the numerous institutions which had sprung up in connexion with the education of cripples. He described how "compensation psychoses" were discouraged, and how the paramount importance of regaining their capacity for work was impressed on soldiers early, the healing of their wounds being treated as a secondary consideration. At the outbreak of the war there was hardly a single institution in Austria for the treatment and education of cripples. The initiative, ingenuity, and capacity for organization shown by Spitzky had done much to promote the welfare of the crippled soldier. His hospital contained 3,500 beds, 1,300 of which were devoted to soldiers with amputated limbs. The hospital included twelve different departments; one ward was set apart for wounds of the knee, another for wounds of the finger, and so on. About three-fifths of all the crippled Austrian soldiers had previously worked on the land, and new occupations on the land were chosen for them. Professor Dollinger said that in Hungary about 5,000 beds had been set apart for crippled soldiers, and institutions had been organized for the education of cripples, usually with a view to farm work. Dealing with the problems of artificial limbs, one speaker insisted that success depended much more on the cripple's desire to work than on the nature of the artificial limb. The standardization of every artificial limb was also insisted on in order that the whole or part of such a limb could easily be replaced. It was also generally agreed that crutches should be dispensed with as early as possible and the cripple be given some temporary artificial limb, be its construction ever so primitive. In this connexion the plaster-of-Paris limb was warmly recommended.

TREATMENT OF WOUNDS OF THE BRAIN.

The Nobel prize winner, R. Bárány, who during the siege of Przemyśl by the Russians was reported to have dispatched his observations on war surgery by aeroplane to the Austrian headquarters, has now published a paper

on the treatment of wounds of the brain.¹ He observed from start to finish sixty cases of bullet and shell wounds of the brain. He learnt to abandon rubber and glass drainage tubes in favour of the "cigarette" drain. In a series of thirty-nine cases in which drainage was by small strips of gutta-percha, recovery occurred in 20.5 per cent. Being impressed by the part played by secondary infection of the brain, he kept the wound closed and undrained in many cases. Out of thirteen in which the wound was closed from the outset, healing by first intention occurred in nine; in three plastic operations on the dura had to be undertaken. He considered that, as a rule, when the wound was not obviously infected and came under treatment within the first twenty-four hours, the best course was to operate at once, to excise the tissues about the wounds of entry and exit, to remove fragments of bone and foreign bodies from the brain, to arrest haemorrhage, and to close the wound carefully with sutures without employing any drain. When an abscess had already formed it should be opened and drained with strips of gutta-percha.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

Fourth-class Assistant Surgeon George Cyril West, of the Indian Subordinate Medical Department, is reported as killed in action. He is the third officer of the I.S.M.D. thus reported as killed within the past three weeks. He was born on August 7th, 1893, attained warrant rank on April 20th, 1914, and prior to the war was stationed at Dalhousie.

Wounded.

Lieutenant N. McCall-Smith, R.A.M.C., temporary.
Assistant Surgeon J. W. Newbold, I.S.M.D.

Died on Service.

Major Francis Courtenay Lambert, R.A.M.C., died of paratyphoid fever on service abroad, on March 29th, aged 37. He was born at Dover on January 22nd, 1879, the eldest son of Lieutenant-Colonel Lambert, late of the Royal Marine Artillery, now of Lyston, Branksome Park, Bournemouth, was educated at Wimborne Grammar School, at Cheltenham College, and at St. Mary's Hospital, and took the qualifications of M.R.C.S. and L.R.C.P. Lond. in 1902, after which he served as house-surgeon at St. Mary's. He entered the army as lieutenant on January 31st, 1903, becoming captain on July 31st, 1906, and major on October 31st, 1914. He was recently serving in Mesopotamia, where he was twice mentioned in despatches.

Major Robertson Stewart Smyth, R.A.M.C., died in a nursing home in London on April 6th, aged 36. He was born on August 18th, 1879, the fourth son of the late William Smyth, of Brookfield House, Banbridge, and was educated at Dungannon Royal School and at Trinity College, Dublin, where he took the M.B., M.D., B.Ch., and B.A.O. in 1904. There he was captain of the Dublin University Rugby fifteen, and played in several international matches in 1903-4. Entering the army as lieutenant on July 31st, 1905, he became captain on January 31st, 1909, and had recently been promoted to major. He had been serving in France from September, 1914, up to last December, when he was invalided. He was mentioned in despatches by Lord French for gallant conduct in the field. One of his brothers is a captain in the Royal Irish Rifles.

Major Walter Linney Hawksley, R.A.M.C.(T.F.), is reported as having been accidentally killed on service on April 4th, aged 33. He was the eldest son of the late Dr. Hawksley, of Southport, and was educated at Liverpool University, where he took the M.B. and Ch.B. in 1904 and the D.P.H. in 1907. After qualifying, he acted as house-surgeon and house-physician of the Northern Hospital, Liverpool, as resident medical officer of the new City Hospital, Fazakerley, and as school medical officer to the Liverpool Education Committee, finally becoming assistant medical officer of health and chief tuberculosis officer, Liverpool, and assistant lecturer in hygiene, Liverpool University. He got a commission as captain in the 2nd West Lancashire Field Ambulance on October 1st, 1911, and had recently been promoted to major. He leaves a widow and two young children.

Major Charles James Holmes, R.A.M.C.(retired), died at his residence in Lancaster on April 5th, aged 58. He was born on October 15th, 1857, the youngest son of Mr. John Holmes, of Athlunkard, co. Clare, was educated at Queen's College, Cork, and took the M.D., M.Ch., and the obstetrical diploma of the Royal University, Ireland, in 1882, also the F.R.C.S.I. in 1890. Entering the army as surgeon on August 2nd, 1884, he became surgeon-major on August 2nd, 1896, and retired on November 16th, 1904. He rejoined on mobilization in August, 1914, and was employed in charge of the military hospital at Bowerham Barracks, Lancaster. He had seen much war service: Sudan, 1885, medal with clasp, and Khedive's bronze star; Sudan, 1896, advance on Dongola, and operations of September 19th, medal with clasp and Khedive's medal; and South Africa, 1900-2, in Cape Colony and Orange River Colony, Queen's medal with one clasp and King's medal with two clasps.

DEATHS AMONG SONS OF MEDICAL MEN.

Underhill, Charles Bertram, Second Lieutenant West Yorkshire Regiment, fourth son of Dr. F. T. Underhill, formerly of Tipton, Staffordshire, now medical officer of health, Vancouver, British Columbia, killed on March 28th, aged 22. He was born at Tipton, educated at Vancouver and at McGill University, and was assistant city analyst at Vancouver. At the beginning of the war he joined the 11th British Columbia Regiment, and came to Europe with the first Canadian contingent. He got a commission in the West Yorks on December 22nd, 1914, and went to the front last September. He was serving as machine gun officer of his battalion when killed.

NOTES.

MR. HUGH M. RIGBY, M.S.Lond., F.R.C.S., has been appointed a consulting surgeon to His Majesty's forces in France, with the rank of Colonel A.M.S.

HONOURS.

The Médaille d'Honneur des Epidémies has been bestowed by the French Government on two members of the staff of British Red Cross Clearing Hospital No. 16, Miss Bradley, matron, receiving the silver medal, and Miss Dorothy Gully, a sister employed in the nursing of contagious diseases, the bronze medal.

MESOPOTAMIA DISPATCHES.

A dispatch from General Sir John Nixon, K.C.B., covering the operations in Mesopotamia from the middle of April to the end of September, 1915, dated January 1st, 1916, was published in the *London Gazette* of April 5th. Among a large number of officers mentioned for good service are the following medical officers:

Operations at Khafajiya, April 24th to June 19th, 1915.—Major H. R. Brown, I.M.S.

Operations at Amara, May 31st to June 4th, 1915.—Colonel P. Hehr, C.B., I.M.S.; Lieutenant-Colonels: H. O. B. Browne-Mason, R.A.M.C.; J. F. Donegan, R.A.M.C.; Captain G. Wilson, R.A.M.C.; Lieutenant R. V. Martin, I.M.S.; Assistant Surgeons E. A. Cotton and E. S. Sheelo, I.S.M.D.

Euphrates Operations, June 26th to July 23th, 1915.—Colonel H. M. Adamson, R.A.M.C.; Lieutenant-Colonel E. Jennings, I.M.S.; Major A. Spitteler, I.M.S.; Captains: P. B. Bharucha, I.M.S.; R. C. Clifford, I.M.S.; R. E. Flowerdew, I.M.S.; F. A. Robinson, R.A.M.C.; Sub-Assistant Surgeons: Mohan Lal, Barkatullah, Fazl Ahmad, I.S.M.D.

Operations at Kut-el-Amara, September 28th, 1915.—Surgeon General H. G. Hathaway, C.B., A.M.S., Staff; Lieutenant-Colonel J. F. Donegan, R.A.M.C.; Majors: S. Anderson, I.M.S.; *F. O. Lambert, R.A.M.C.; Captains: K. K. Mukerji, I.M.S.; J. Startin, R.A.M.C.; Lieutenant F. T. Simpson, R.A.M.C.; Assistant Surgeons: A. S. Morarji, H. J. Luxa, S. A. de Souza, I.S.M.D.; Sub-Assistant Surgeons: Mithu Lal, S. Manikkam, I.S.M.D.

Operations from November 6th, 1914, to April 14th, 1915 (previously published in *Gazette of India*).—Colonel P. Hehr, C.B., I.M.S.; Staff; Lieutenant-Colonels: J. Hennessy, F. J. Palmer, H. M. Adamson, F. J. Donegan, H. O. B. Browne-Mason, D. J. Collins, R.A.M.C.; and G. B. Irvine, I.M.S.; Majors: E. Bennett, H. A. Bransbury, J. C. Foster, and *F. O. Lambert, all R.A.M.C.; and J. H. Horton, D. S. A. O'Keefe, H. R. Brown, and R. E. Cook, all I.M.S.; Captains: A. T. J. McCreary, R.A.M.C.; and R. E. Wright, T. H. Hislop, D. Arthur, C. H. Barber, H. B. Short, C. C. Shaw, G. F. Graham, R. Knowles, J. J. H. Nelson, F. O. Fraser, and E. E. Stanger-Leathes, all I.M.S.; Lieutenants: E. B. Allnut and I. M. Burnett, both R.A.M.C.; N. K. Bai and L. A. P. Anderson, both I.M.S.; Assistant Surgeons, I.S.M.D.: W. H. Brown, T. H. S. Hutton, E. A. Cotton, L. C. Raphael, H. Vincent, J. V. Fernandez, J. H. T. Pacheco, H. N. Murphy, and A. F. Phaire, Sub-Assistant Surgeons, I.S.M.D.; V. L. U. Ram Pandit, Mohan Lal, G. R. Hariba, V. S. Nayakar, M. Ranasarni, Sundar Singh, K. W. Khuperkar, and S. M. Dadashahib, Dr. Arthur Bennett (American Mission Hospital).

* Since dead.

† Killed in action.

MEDICAL OFFICERS WANTED.

14th Mounted Brigade Field Ambulance.

There are vacancies for medical officers in this unit. Apply to Major J. Hamilton, Cricket Ground, Canterbury.

21st Home Counties Casualty Clearing Hospital.

Three medical officers are required for this unit. Application to the Officer Commanding 21st Home Counties Casualty Clearing Hospital, Halton Camp West, Tring.

¹ Beiträge zur klinischen Chirurgie, kriegschirurgisches. Heft 8. Abstract in *Muench. med. Woch.*, January 4th, 1916.

England and Wales.

THE number of patients (pauper, criminal, and private) for whom the London County Council was responsible to find accommodation at the beginning of the present year was 20,886, as compared with 21,539 twelve months previously, while the total number of patients, including those in the Metropolitan Asylums Board's institutions, in workhouses, and with relatives and friends, was 28,252, as compared with 29,211 at the beginning of 1915. It is the first time since the Council has been the responsible authority that decreases have been recorded in both these totals. The decrease of 653 in the number of lunatics under reception orders is made up of 363 males and 290 females, and as the ratio of the sexes in the asylum population is 9 males to 11.8 females there is a proportionately greater reduction of the male insane. It is assumed that the great decrease in pauperism is reflected in these figures.

ROYAL COMMISSION ON UNIVERSITY EDUCATION IN WALES.

A Royal Commission on University Education in Wales has been appointed "to inquire into the organization and work of the University of Wales and its three constituent colleges, and into the relations of the university to those colleges and to other institutions in Wales providing education of a post-secondary nature, and to consider in what respects the present organization of university education in Wales can be improved, and what changes, if any, are desirable in the constitution, functions, and powers of the university and its three colleges."

The members of the Commission are: Viscount Haldane (Chairman); Professor W. H. Bragg, F.R.S., Quain Professor of Physics in the University of London; the Hon. W. N. Bruce, C.B., a Principal Assistant Secretary under the Board of Education, and Sir Owen M. Edwards, M.A., Chief Inspector of the Welsh Department of the Board; Mr. W. H. Hadow, D.Mus., Principal of Armstrong College, Newcastle; Mr. A. D. Hall, F.R.S., a Commissioner under the Development Act; Sir Henry Jones, M.A., D.Litt., Professor of Moral Philosophy in the University of Glasgow; Sir William Osler, Bt., F.R.S., M.D., Regius Professor of Medicine in the University of Oxford; Miss Emily Penrose, M.A., Principal of Somerville College, Oxford. The secretary to the Commission is Mr. A. H. Kidd, of the Board of Education, to whom all communications should be addressed.

LIVERPOOL ROLL OF HONOUR WEEK.

The Lord Mayor has issued an appeal to all classes in Liverpool to provide a special fund for supplementing Government pensions to widows, orphans, and dependents of Liverpool men who fall in the war, and to provide allowances to deserving cases in which pensions have been refused. Every class in the city will be canvassed during the week May 7th to 13th. The Liverpool Medical Institution has already sent a circular to the medical profession of the city, signed by its president, Dr. Charles J. Macalister, Dr. Hubert Armstrong, secretary, and Dr. Llewellyn Morgan, treasurer. It is desirable that the subscriptions from each profession, vocation, and trade should be contained in one list, and the medical profession has already subscribed many generous amounts since April 1st. This local fund will be administered under the control or direction of the Lord Mayor, in accordance with the principles and policy of sympathetic treatment hitherto adopted in connexion with Town Hall Fund.

LIVERPOOL MEDICAL INSTITUTION.

At the last pathological meeting, held at the Liverpool Medical Institution, Professor Beattie demonstrated a simple method of anaerobic culture which meets the difficulty in obtaining pyrogallol acid. Sterilized white vaseline is the medium which acts like a plug over the culture medium in the test tube and occludes the air. Professor Beattie showed luxuriant growth of anaerobes with the vaseline plug raised by the gas evolved during their growth, and the complete absence of growth of aerobic micro-organisms in similarly prepared test tubes. Professor Ernest Glynn gave a demonstration of various ulcerative processes of the oesophagus, especially its

cardiac end. To prevent *post-mortem* digestion the tissues were fixed immediately after death by the introduction of formalin into the oesophagus and stomach. Professor Glynn has used the method in several hundred cases for over fifteen years. Numerous macroscopic and microscopic slides showing ulceration in varying degrees of evolution were shown in the lantern. Professor E. Glynn accounted for the clinical symptoms of pyrosis, heartburn, and waterbrash by reference to the morbid changes in the cardiac end of the stomach and the oesophagus which the formalin method had rendered apparent to the naked eye.

Scotland.

THE Glasgow Corporation has decided to proceed with the scheme for a municipal dairy to supply milk to the hospitals. The corporation requires 156,000 gallons of milk a year. The farmers who contracted have refused to submit their herds to the tuberculosis test.

Dr. Templeman, M.O.H. Dundee, in his annual report, states that the infant mortality-rate for 1915 was 209, the highest figure since 1893, when it was 217. The high rate in 1915 was due to whooping-cough and measles, and to an increase in the number of deaths from bronchitis and pneumonia accompanying these diseases.

At the 106th annual meeting, on April 7th, of the Edinburgh Royal Institution for the Education of Deaf and Dumb Children it was reported that the new buildings—an educational wing with twelve classrooms, etc.—had been added without trespassing upon capital. Dr. J. W. Ballantyne spoke of the three groups of deaf-mutes—the acquired, the hereditary, and the antenatal but non-hereditary, and pointed out that in every one there was now the hope of prevention. The acquired could be lessened by the decrease in the infectious fevers, the hereditary by the restriction of intermarriages between deaf and dumb persons, and the antenatal but non-hereditary by the campaign against the venereal diseases.

The total amount received by the Lord Provost of Glasgow down to the end of last week for the Princess Louise Scottish Hospital for Limbless Sailors and Soldiers at Erskine was nearly £38,000. Among the subscriptions received was one of £100 from Mr. James J. Hamill of Columbus, Ohio, who, in his covering letter, said that he desired "to help to some slight extent in alleviating the pain, and suffering, and hardships of the poor fellows at the front who are so bravely sacrificing everything in this righteous cause."

Good progress is being made with a scheme of the Scottish Veterans' Garden City Association for the housing and care of permanently disabled soldiers and sailors. The site is immediately to the east of the present village of Longniddry on the north side of the main road from Edinburgh. Plans for the laying out of the grounds have been prepared, and the construction of the houses will be commenced shortly. Part of the ground is reserved for small workshops, a public washhouse, and a public hall. The houses will be of three sizes, with one room, two rooms, and three rooms respectively, in each case with kitchen, scullery, and other necessary accommodation.

EDINBURGH CHILDREN'S HOSPITAL.

At the annual meeting of that great institution, the Royal Edinburgh Hospital for Sick Children, it was reported that the work had gone on unimpaired, but the deficit of over £4,000 on ordinary income was a source of grave anxiety. Lord Strathclyde, in moving a resolution commending the hospital to the liberality of the public, expressed high appreciation of the self-sacrificing devotion of the medical and surgical staff. Many had entered the military services; all honour, he said, to them, but all honour also to those who remained behind to carry on not a diminishing but an increasing work. The Rev. Dr. Fisher, in seconding, testified to the efficiency, ability, and economy with which the work of the hospital was conducted. He referred to the falling birth-rate, which, he said, was one of the most ominous and sinister facts in the social life of the time, and added that it was a national duty to preserve the lives of the children, for the future of the empire depended not upon the young men and women of to-day, but upon the children coming up behind them.

Ireland.

DR. ROANTREE, of Bray, M.O. for one of the Rathdown dispensary districts, having accepted a temporary commission in the R.A.M.C., the guardians have appointed the locumtenent of his private practice to be his deputy at the dispensary, and have allowed Dr. Roantree half pay during his absence.

Dr. E. C. Thompson, of Omagh, who has been surgeon to the Tyrone County Hospital for over forty-one years, has been appointed deputy lieutenant for the county. He was for some years M.P. for North Monaghan.

The means to be taken to lessen infantile mortality were discussed at a meeting of the Joint Committee of the Irish Women's Local Government Associations held in Dublin recently. It was pointed out that in the country parts of Ireland the mortality was lower than in England, but higher in the cities. The pasteurized milk dépôt in Dublin had done very good work; the deficit, which was between £300 and £350 a year, was made up by the founder, Lady Aberdeen. The attempt to induce the corporation to take it over and run it as a municipal undertaking had not been successful.

THE PETROL SUPPLY.

Sir Matthew Nathan, Under Secretary to the Lord Lieutenant, has addressed to the members of the medical profession who use motor cars or motor cycles, whether as general practitioners, consultants, or medical officers engaged as such in the public service, a letter dwelling on the necessity for economy in the consumption of petrol in face of the difficulty caused by the temporary diminution of shipping and transport facilities. At the same time he lays stress on the anxiety of the authorities to provide for all necessary public services according to their importance, and the need of rendering all possible aid to the medical profession in its work is fully recognized. With the view of avoiding the danger that this work might be hampered in the future, each medical man who thus uses a motor car in his practice has been requested to furnish the same particulars as to his car and consumption of petrol as have been asked for in England.

AMALGAMATION OF UNION WORKHOUSES.

The cost of upkeep of many of the workhouses in Ireland is absurdly large in proportion to the number of inmates. At present a workhouse is maintained in every union, and the amalgamation of unions, the only authorized method of reduction, is not convenient in all areas. The problem has lately been investigated in co. Tyrone. The number of inmates has been reduced by the operation of the Old Age Pensions Act and recently by war conditions, while the great rise in the cost of fuel and provisions has accentuated the capitation expenditure. The smaller unions object to complete amalgamation with the larger, but means should be found to end the extravagance involved in keeping up large workhouses for a mere handful of paupers, and at the same time to keep the smaller unions in existence for the purposes for which they are still needed. This could be done if some of the boards of guardians closed their workhouses wholly or in part, and boarded out their paupers in adjoining unions, while the union and the board of guardians remained for the purposes of administering the Medical Charities Act and outdoor relief. An Act has been passed authorizing the transfer of paupers from one workhouse to another "in connexion with the present war." The Tyrone County Council and all the local boards have adopted resolutions in favour of the immediate submission to Parliament of a short amending Act to delete these words. The resolution has been sent to other county councils, and will, it is hoped, meet with general support.

THE President of the Republic of Venezuela has issued a decree establishing a medical school at Caracas.

THE United States Senate has now before it a bill providing for the establishment in the Department of Justice of a bureau for the study of the criminal, pauper, and defective classes. Its work would include laboratory investigations and the collection of sociological and pathological data.

Correspondence.

INDUSTRIAL FATIGUE AND ITS CAUSES.

SIR,—Your leading article on "Industrial Fatigue" in your issue of April 8th has many comments that are equally applicable to fatigue in our own profession. There must be a considerable body of general practitioners who are doing and have been doing much extra work during the past two years, and who have not had any kind of holiday since 1913. These men, even with the best of good will to do all they can to help, are feeling "fed up." Locumtenents are scarce, expensive, and fastidious, and, as local schemes for arranging holidays only add to the burdens of already fatigued colleagues, I should like to ask if it be not possible to dilute the labour of the general practitioner during the coming summer with fourth and fifth year students. These young men could work a practice under the supervision of a neighbouring colleague, who would act as the deputy of the man on holiday. If the General Medical Council and the British Medical Association could see their way to accept and foster this suggestion, the details of the employment of fourth and fifth year students could be arranged later. I am quite convinced that unless something is done to give general practitioners a short rest and holiday many will break down, to the disadvantage of both civil and military populations.—I am, etc.,

Warrington, April 9th.

J. S. MANSON.

PERNICIOUS ANAEMIA AND ERYTHRAEMIA.

SIR,—I can trust Dr. O. Leyton not to misinterpret my presumption in venturing—without any clinical particulars beyond those published on p. 484—to express a view of the remarkable facts he has observed which is at variance with his own unhopeful conclusion. He succeeded in doubling the haemoglobin and in nearly doubling the red count within one week. Why, then, should the patient have left the hospital after a year's treatment much the same in condition as he had entered it? That week's work was worth renewing—on the same plan suitably modified. We owe to him the discovery seemingly, let us hope of a cure, but at any rate of a great fact—that for pernicious anaemia erythraemic blood possesses the double qualification, special to all potent curative agents, of a remedy and of a poison. A little of them can stimulate that which too much will destroy. The dose first injected was conspicuously beneficial, although such as to produce toxic effects closely akin to anaphylaxis. The second, four times larger, was wholly toxic. As it stands, that demonstration would seem to encourage minimizing any future dose instead of increasing it, and repeating it steadily at its optimum of individual efficiency as between donor and recipient, with any dilution or artificial modification that experience might indicate. That attempt strikes one as more promising than its converse, merely hinted at in the paper, that of curing erythraemia with the blood of pernicious anaemia. The sooner theories are disproved or improved, surely the better. For years, in dread of alarming symptoms once witnessed, I had denied asthmatics their adrenalin—till Dr. Hertz published the safety and efficiency of its minimal doses. We shall, indeed, thank Dr. Leyton for not having long buried his find if, as seems possible, good oil has been struck.—I am, etc.,

London, W., April 2nd.

WILLIAM EWART.

NOMENCLATURE OF TYPHOIDAL DISEASES.

SIR,—Since the differentiation of the typhoid group of diseases into the three varieties caused by the Eberth-Gaffky bacillus, the *B. paratyphosus* A and the *B. paratyphosus* B respectively, a need has arisen for one word which can be used for the whole group in common. In the large majority of cases it is quite impossible to diagnose clinically the three infections one from the other, and it is not always possible to obtain readily bacteriological aid. There is no necessity, however, to coin another word as we possess two already which are used interchangeably—"typhoid" and "enteric." I suggest that the word "enteric" be used to denote all or any of the three infections above mentioned, and any similar that may hereafter

be differentiated, and that the word "typhoid" be restricted to cases of infection by the Eberth-Gaffky bacillus.—I am, etc.,

Homerton, N.E., April 10th.

E. W. GOODALL.

JEJUNOSTOMY AND JEJUNO-COLOSTOMY.

SIR,—Mr. Sampson Handley, in his paper in the JOURNAL last week (p. 519) refers to a paper of mine published six years ago in the *Archives of the Middlesex Hospital*, wherein I advised jejunostomy in cases of post-operative paralytic obstruction. He thinks it would probably fail. He opines wrongly; it is most successful.

In a future issue of your JOURNAL I hope to publish another paper on the subject supported by six successful cases.

Mr. Handley suggests jejuno-colostomy and caecostomy, which is in effect a jejunostomy, with the difference that the drainage from the jejunum takes a course through a segment of the large intestine instead of reaching the exterior direct.—I am, etc.,

London, W., April 11th.

VICTOR BONNEY.

MANY NAMES FOR THE SAME THING.

We have received from Messrs. Burroughs, Wellcome, and Co. a letter, the following passages from which seem fully to state their position:

With regard to the editorial article in your issue of the 8th inst., relative to the use of the word "Tolamine" as a short title for para-toluene-sodium-sulphochloramide, we suggested the use of this word to the authors of the research in place of chloramine or chloramine-T, the names they gave to the substance, because the word chloramine has been used by John Wyeth and Brother, Philadelphia, for at least twenty-five years to denote a compound chloride of ammonium pastille manufactured by them.

We made our position in the matter perfectly clear to the investigators, and gave them the option of adopting "Tolamine" as a common word for the substance, but as they did not agree to this suggestion, we then explained that it was impracticable for us, in the circumstances we had mentioned, to use the word chloramine or chloramine-T (the latter title still containing the word chloramine), and we should therefore issue the preparation under the word "Tolamine," and register it as our trade mark.

In our opinion the use of the word chloramine involves the danger of using one name for many substances, as, quite apart from the confusion which will arise with the existing proprietary preparation, chloramin and chloroamine are applied to the simple compound NH_2Cl , and further, there is additional risk of confusion with the *Codex* preparation chloramide.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following degree has been conferred:

M.D.—A. L. Pearce Gould.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on March 22nd.

Recognition of Teacher.—Mr. H. S. Souttar was recognized as a teacher in surgery at the London Hospital Medical College.

M.B., B.S. Examination.—A revised syllabus in forensic medicine for the M.B., B.S. examination for internal and external students was adopted for examinations to be held in and after the session 1917-18.

Presentation Day.—The presentation of students to the Chancellor will take place on May 10th at 3 p.m., and a service for members of the University will be held at Westminster Abbey at 6 p.m.

Dixon Fund.—Applications for grants from the Dixon Fund, which is allocated annually for the purpose of assisting scientific investigations, must be received by May 15th. Particulars can be obtained on application to the Academic Registrar.

UNIVERSITY OF GLASGOW.

GRADUATION CEREMONY.

At the graduation ceremony held in the Bute Hall on April 8th, the degree of M.B., Ch.B. was conferred by the vice-chancellor, Sir Donald MacAlister, upon fifty-two graduates, ten of whom were ladies. Practically all the male recipients have, it is understood, signified their intention of entering the military or naval medical services. Professor Bryce, Dean of the Faculty of Medicine, presented the graduates in medicine. At the conclusion of the capping ceremony the Vice-Chancellor, addressing the graduates, said: "You have now been admitted

into the ranks of a profession which expects, and expects with confidence, that you will do your duty to your fellow men. That duty demands that you shall exercise all your skill and knowledge on their behalf, and, still more, that you show yourselves humane, unselfish, upright, and devoted. Whether you work at home or abroad, whether your practice be civil or military, you are put on your honour to render your highest service to your country and your King. A great example has been set you by the Glasgow men and women who have made famous throughout the world the name of its schools of medicine. You are now deemed fit to take your place beside them. Our earnest prayer is that you will equal or surpass them in all that is worthy and of good report. In the name of the university I give you its benediction, and commend you, in war and peace, to God's care and keeping."

The following is a list of the recipients of the degree of M.B., B.Ch.:

*W. D. Allan, J. Alston, W. Baird, Christina B. Buchanan, D. Cameron, J. Chalmers, D. H. Coats, W. K. Council, A. F. Cook, A. S. Cook, W. G. Cook, J. N. Cruickshank, A. Davidson, Jane B. Davidson, J. Dunbar, J. B. Fisher, M. M. Frew, T. R. Fulton, W. H. Gibson, Jessie C. Gilchrist, J. Glaister, J. S. Kinross, G. Kirkhope, W. J. B. Lavery, R. Lindsay, Dorothy McCubbin, J. W. Macfarlane, J. MacInnes, K. S. Macky, D. M'Lauren, Elizabeth S. Martin, F. R. Martin, J. M'D. Matheson, W. W. Morrison, A. Morton, W. O'Brien, J. A. Paterson, T. S. Paterson, J. H. Paul, W. J. Poole, T. J. D. Quigley, J. Richardson, A. W. Ritchie, G. W. Ronaldson, Mary H. Routledge, Mary I. Sinclair, Jane Stalker, W. M. Stewart, J. L. Torley, R. S. Weir, C. A. Whittingham, Marion B. D. Wilson.

* With distinction.

† Also graduated as M.A.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—T. A. du Toit, R. B. Forgan, W. H. Kerr, R. F. Kerr, Lizzie R. Clark, M. H. Carleton, J. B. Singh, G. C. Field. *Passed in Biology*: P. E. Malloch. *Passed in Chemistry*: J. Murray, A. W. Smith.

SECOND COLLEGE.—A. E. Hempleman, R. E. Hopton, A. S. Hughes, E. L. Adendorff, Rebecca Goodman, J. K. Steel, W. Gibb. *Passed in Anatomy*: H. W. Howatson. *Passed in Physiology*: J. J. van Nickirk, G. S. Woodhead, J. F. Cook.

THIRD COLLEGE.—C. V. Samwel, E. B. Bronstorph, G. P. de Silva, H. Shaw, A. I. Neek, C. R. C. Moon. *Passed in Pathology*: M. A. K. Mofreh, Eliza J. Stuart, P. M. Fernando, D. Stewart. *Passed in Materia Medica*: D. G. Howard.

FINAL.—Z. A. Green, J. E. Ainsley, J. C. Badwell, H. C. A. Haynes, B. C. Haller, J. Byrne, J. V. R. Roban, S. J. Abrahamis, J. Blackburn, C. Harris, A. Caston, R. C. W. Spence. *Passed in Medicine*: S. W. Hoyland. *Passed in Surgery*: J. J. Curtin. *Passed in Midwifery*: J. Adami, J. J. Curtin. *Passed in Medical Jurisprudence*: J. H. Blackburn, R. V. Clarke, C. G. Book, W. McKelroy, M. A. White.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE following have been admitted as Licentiates:

J. F. Coffey, K. Elmes, H. Gerrard, J. Magner, C. A. R. McCay, D. McCormack, J. A. McKinnon, A. J. Neilan, J. P. Pegum, G. C. L. Woodroffe.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

PRIMARY EXAMINATION.—Part I. *Biology*: K. J. H. Davies, H. T. M. Price. *Chemistry*: K. J. H. Davies. *Materia Medica and Pharmacy*: L. E. A. B. Farr, T. F. Reason. Part II. *Anatomy*: W. M. Anthony, G. R. Aspinwall, W. A. Bibby, T. L. Bonar, J. Brodetsky, K. B. Chapple, E. S. Davies, D. A. Dyer, J. Gordon, J. Gorsky, W. R. G. Harris, R. A. Hickley, A. H. Hill, O. B. Hillman, C. Holmes, R. E. Jenkins, E. F. J. Jones, R. M. Jones, F. W. Kemp, N. H. Kettlewell, W. Kilroe, F. Lloyd-Williams, L. Lyne, J. J. M. Macdonnell, J. S. Moore, G. E. Morgan, H. S. Morris, W. R. Ranson, G. V. Richards, S. Robinson, A. H. Shelswell, H. W. Southgate, E. A. Sparks, J. Stephen, A. C. Teuton, C. de B. Thomson, A. E. Young. *Physiology*: W. M. Anthony, G. R. Aspinwall, J. Brodetsky, E. S. Davies, J. Gorsky, W. R. G. Harris, A. R. Hill, O. S. Hillman, C. Holmes, R. E. Jenkins, E. F. J. Jones, F. W. Kemp, J. S. Lewis, P. Lloyd-Williams, L. Lyne, J. J. M. Macdonnell, J. S. Moore, G. E. Morgan, H. S. Morris, W. R. Ranson, G. V. Richards, A. H. Shelswell, H. W. Southgate, E. A. Sparks, A. C. Teuton, A. E. Young.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following were approved at the examination held at the termination of the fiftieth session of the school:

*W. N. Leak, †H. Bayon, Miss V. G. Field, E. A. Blok, J. A. Beels.

* Dr. Leak gains the "Duncan" Medal, this being awarded to the student who obtains the highest aggregate of marks.

† With distinction.

EXCHANGE.

LIEUTENANT R.A.M.C., Regt. M.O., desires to change with officer holding a position in base hospital, casualty clearing station, or ambulance train, the latter preferred. Address, No. 1500, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Obituary.

SIR ALEXANDER RUSSELL SIMPSON, Kt.,
M.D., D.Sc.(Hon. CAUSA), LL.D.,

EMERITUS PROFESSOR OF MIDWIFERY AND THE DISEASES OF WOMEN
AND CHILDREN IN THE UNIVERSITY OF EDINBURGH.

THE hand of death has removed another of the band of professors who in Edinburgh University in the fourth quarter of the last century made its medical teaching known and respected all over the world. Sir Alexander Simpson has not long survived his friend and colleague Sir William Turner; indeed it is not more than six weeks since Sir Alexander published in this JOURNAL (p. 330) some most interesting reminiscences of the late Principal. A motor accident in the street on the evening of April 6th has ended in a moment a long and useful life, and brought an added sorrow to the many griefs which are not far from every one in these troublous times. For the place of the Emeritus Professor of Midwifery will not easily be filled in medical, philanthropic and evangelical Edinburgh.

Born in Bathgate, West Lothian, on April 30th, 1835, Alexander R. Simpson was 35 years old when he was elected to succeed his uncle, Sir James Young Simpson, in the Chair of Midwifery in Edinburgh University in 1870. For thirty-five years he not only occupied but conspicuously adorned that high office; and when in 1905 he retired, it was not because of failing powers, but because, to use his own words, "there was always a risk that the ageing incumbent of a chair might become an incubus upon it." His friends did not share his fears, and Sir Alexander might well have continued for at least another five years; but the full ten years of comparative freedom from professional work, which by retiring he thus was able to have at the close of his life, enabled him to do many things which he had been longing to accomplish, including a journey round the world and a survey of the mission field, and must have brought him a great deal of contentment, rounding off a life which had been marvellously complete and well ordered. One sharp grief divided these last ten years into two parts, the death of Lady Simpson in 1911; but Sir Alexander did not falter in his path, although he thenceforth walked alone, and there can be no question that his sorrow drew from him that tenderest of all his medico-evangelical booklets—*The Broken Heart of Jesus*.

The events of the first thirty-five years, before Sir Alexander stood "nel mezzo del cammin' di sua vita" as professor of midwifery in Edinburgh, may be briefly summarized, although they were indeed potent times whose moulding and determining influences ruled all the years which followed. He was educated at Bathgate Academy and at Edinburgh University; and, as the system of medical apprenticeship had not at that time quite died out, he had, as he said in his valedictory address (in 1905), the "singular good fortune to be apprenticed to Professor Goodsir, although the relationship did not help him much in learning to cure disease." But it brought him under the spell of a man of genius "who was a tireless toiler," and when, after graduation (M.D., 1856), his young apprentice came to bid him farewell preparatory to post-graduate study at Berlin and in Montpellier, Goodsir said to him, "Mr. Simpson, see that you go regularly to church every Sunday," and added, with a smile, "there's no better way to learn German." In the years which succeeded, tireless toil, going regularly to church, and the learning of German and of any other language (French, Italian, Dutch) which served to bring obstetrical knowledge to him, all continued to fill Simpson's days to the full. When he returned to Edinburgh he had the privilege of seven years spent as assistant to his uncle, Sir James, who was then at the zenith of his reputation and powers; and the nephew grew quietly into greatness beside that massive figure. There followed five years of private practice in Glasgow, where from "the corner house in Blythswood Square" Alexander Simpson daily, and often nightly too, set out on his errands of healing, and built up such a reputation for himself, and gathered round him so large and influential a *clientèle*, that when in 1870 he stood as candidate for the professorship of midwifery in Edinburgh, his friends in the great city of the west openly said that if he failed to seat himself in the chair in Edinburgh, he had still a feather bed to lie on in Glasgow. There can be no doubt that these five strenuous and

independent years did more than anything else could have done for the upbuilding of Sir Alexander Simpson, and sent him through to his heavy duties in the east with a determination and a capacity to overcome obstacles which were the delight of his friends and a surprise to those who were opposed to him. When the great contest and trial of strength were over and Simpson was installed in the chair of midwifery (1870), it stands to his lasting credit that without yielding one essential point he nevertheless steadily drew over to the circle of his friendship many who had been averse to his coming, and did so by the simple, kindly acts of a Christian gentleman, ready to forgive and quick to forget.

For the next thirty-five years (1870–1905) Simpson dominated Edinburgh obstetrics and gynaecology (for at that time the university chair carried with it the appointment to one of the gynaecological wards in the Royal Infirmary). His lectures were always filled with the latest obstetric knowledge of the Continent, and he early recognized the value of the gynaecological work of the Americans; he saw the number of students attending his class rise to little short of 300; he instituted a summer class of operative midwifery and gynaecology, which came to be more and more largely attended; he did his share of the teaching of clinical gynaecology, in association with the Professors of Clinical Medicine in the Royal Infirmary, and his Thursday gynaecological demonstrations were always well attended. He witnessed the birth of abdominal surgery and, indeed, took a great share in it, feeling his way by his operations (ovariotomies and the like) in the Buchanan ward towards the perfected science of the present day, himself reaching an outstanding position as one of the most successful of hysterectomists, and placing the surgeons under a debt of gratitude which many amongst them readily acknowledged. He was on duty for a quarter of each year as physician at the Royal Maternity Hospital (named also, in honour of his uncle, the Simpson Memorial), where he performed the first Porro-Caesarean section in Great Britain; he was swift to apprehend the value of the axis-traction principle introduced by Tarnier of Paris into the construction of the forceps, and through his immediate application thereof to the J. Y. Simpson forceps he carried this great obstetric advance to Austria and to Germany at the same time that he brought it to his own land; the basilyst invented by him is, in the opinion of many to-day, the best known perforator for the head, including the basis cranii, and the basilyst tractor has also much to recommend it. He rarely missed a meeting of the Edinburgh Obstetrical Society, of which he was thrice president, or an opportunity of saying a kind and encouraging and at the same time critical thing of the work of the younger men presented to it. He worked himself and he encouraged his assistants to work; and when the work was done and recognized as good he distributed the praise most generously, keeping little or none for himself. It was a beneficent and a benevolent domination that he exercised over Edinburgh obstetrics for thirty-five years. But he did more: he saw to it that midwifery got and maintained its right and proper and important place in the medical curriculum of the university; he took with him and established on ever surer foundations the reputation of Scottish midwifery across the border, in England, in Europe, in America, and even in far-off Japan; there was hardly an international congress of medicine or of gynaecology at which he did not attend and to whose debates he did not contribute; and he brought back to his Alma Mater and to his classroom and ward the rich spoils of his experience and observation abroad, with the result that many of his colleagues and assistants were early familiar with the best that the Continent and America could give. It was during his visit to the International Medical Congress at Washington in 1887 that he made an important contribution to an attempt to introduce uniformity into the nomenclature of obstetrics, and distributed among the medical men attending the congress copies of the Gospel of Luke and the Acts of the Apostles, printed (without chapters and verses) in the form of a separate work, with the title "Christ and the Beginnings of Christianity, by a Physician of the First Century." One suspects—nay, one is sure—that he enjoyed more fully the giving away of the booklet than the presentation of the uniformity scheme, and he always spoke with supreme satisfaction of the medical men who accepted copies without a suspicion that they

were receiving portions of the sacred scriptures. For some years he was dean of the medical faculty in his own university; he was president of the Royal College of Physicians of Edinburgh, and he was also honorary president of the Glasgow Obstetrical and Gynaecological Society (1896-8). He was an honorary or a corresponding Fellow of many American and Continental societies; Manchester gave him its honorary Doctorate of Science, and his own university added the LL.D.; and, to crown all, he received the honour of knighthood in 1906. He did not perhaps write so much himself on the subjects which he taught as he inspired others to write, but the volume of *Contributions* which he published in 1879 contained not a few outstanding articles, including the learned one on Laah's theory of flexion in the mechanism of labour. His Harveian address on *Life and its Epiphanies* (1911) was also a notable production.

It has not been possible to speak of his professional life without referring to the religious side of his activities. The two were indeed so intertwined in him as to be inseparable. Their close connexion was equally evident to the students attending his class, to the medical men who came into touch with him, to his colleagues in the university and medical societies, and to his patients and friends. As a consequence he was not only asked to preside over such a medico-religious body as the Edinburgh Medical Missionary Society and came naturally to take a leading part in Professor Henry Drummond's evangelistic campaign among the students, but he was also drawn (always willingly) into all sorts of work in connexion with the United Free Church of Scotland (in kirk session and general assembly), and for many years he directed and presided over the activities of the Carrubber's Close Mission. He also was greatly interested in the temperance cause. (He was returning from a temperance meeting when he was knocked down by a motor car.) Further, his religion was so truly a part of all his work that a unity was produced which was most impressive and convincing.

There are not a few sides of Sir Alexander Simpson's life and work which have not even yet been touched upon. His hospitality, catholic in its extent; his liberality, public and known, but (far more) private and little known; his sympathy with all in distress; his admiration for all things Scottish; his appreciation of the best in literature; his pronounced Liberalism in politics; his keenness (this may be a surprise to some) to bring down a pheasant or a grouse; and his never-failing good humour and friendliness—these are sides of him which need to be held in mind in forming a full and complete picture of the man who used the words, "not in himself a great man, but one who had been a friend of great men," to paint his own likeness. He was a greater man than he was ready to admit.

At the general election in December, 1910, Sir Alexander Simpson unsuccessfully stood for the Universities of Edinburgh and St. Andrews against Sir Robert Finlay. Sir Alexander leaves four sons and a daughter. The eldest son, J. Y. Simpson, is professor of natural science in the New College, Edinburgh; the second, George F. Barbour Simpson, has followed in his father's footsteps and has specialized in obstetrics and gynaecology; a third is a clergyman in Glasgow. Lady Simpson was a daughter of Mr. George Barbour of Bonskeid, Pitlochry, and sister of Dr. Freeland Barbour, P.R.C.P.E.

The funeral, a private one to the Grange Cemetery, Edinburgh, took place on Monday, April 10th; and there was a memorial service in St. George's U.F. Church on Wednesday, April 12th, attended by the Session of St. George's (the late Sir Alexander was the father of the St. George's Session), and such public bodies as the Royal College of Physicians, the University, the Edinburgh Medical Missionary Society, etc.

Sir HALLIDAY CROOM, Professor of Midwifery in the University of Edinburgh, writes:

We who remember Sir Alexander Simpson's appointment to the Chair of Midwifery in the University of Edinburgh will recall that his position was an extremely delicate and difficult one. He was overshadowed by the fame of his illustrious predecessor. His sureness of perception and infinite tact, combined with his abounding kindness, carried him triumphantly through that anxious and somewhat disquieting period. To those of us who were asso-

ciated with him at that time his modest conduct and his immediate and courageous application to the work of his chair will always remain a delightful memory. His subsequent distinguished career amply justified his selection by the patrons.

During the long period of his incumbency of the Chair of Midwifery he took an active and lively interest in all departments of academic work. He was a careful, conscientious, and interesting teacher. His lectures were most comprehensive, with perhaps too great a wealth of detail.

On first assuming charge of the gynaecological wards in the Royal Infirmary, coming as he did from Glasgow, where gynaecological operative work was not then a feature, he at that time fought rather shy of the major operations, then practically monopolized by Keith. Before long, however, his ward was filled with abdominal work, which in those days was in its comparative infancy. As time went on his keenness for operating grew apace. His methods grew more and more exact; he was deft and quick with his fingers, rapid and meticulously careful in his technique—as his assistants knew full well—the result being that ultimately he had very few equals, and certainly no superior, in operating. After his frequent spring visits to France and Germany he came back full of fresh ideas and methods, and those were promptly put in practice in his ward. He was a constant student, and scarcely any of the advances in operative gynaecology missed his notice.

He took the deepest and most profound interest in students, not only in their professional work but in their religious life, in which his personality played a prominent part. In all movements for the benefit of students' higher life he took a foremost part, and many mature men of the present day can bear witness to the influence he had upon their lives. This was never better shown than in the interesting time of Henry Drummond's work among the university students, into which he threw himself with characteristic ardour. He was a man of very broad sympathies and wide benevolence, and he contributed handsomely to most of the philanthropic institutions in the city, and to those who appealed to him personally for help he was most open-handed.

Nothing was more delightful than to see him at foreign congresses, most of which he attended, from Moscow to Washington. He was then in his element, whether it were mounting the rostrum beside the president or in the midst of a festive luncheon or dinner party. Everybody knew him and he knew everybody. His name, indeed, was a household word at every congress. There can be no question that at such gatherings he was a universal favourite, for he had a wonderful geniality and fluency of speech, even in a foreign language. His facility in public speaking was certainly one of his most striking characteristics. He spoke with equal ease and grace in a public meeting, a class-room and a medical or church congress. He was particularly happy in his after-dinner speeches, though he was aided by neither alcohol nor tobacco.

His hospitality was proverbial. At his table were to be found men from all countries. Foreigners made prolonged visits to him, and it is a remarkable fact that no one was more hospitable than he was to Germans, who used to be his frequent guests, and that he met his death by the darkness produced over the city by the fear of Zeppelin raids.

He spent an ideal life. His winter was absorbed in the duties of his university chair, varied by philanthropic and religious work. Immediately the session finished in March he went abroad, either to Italy or France, until the beginning of the summer session in May. During the summer, in order to be in touch with his hospital and university work, he had a house in the neighbourhood of Edinburgh, and every autumn he rented a mansion in the country, where he enjoyed shooting—for he was an excellent shot—and similar sport. Each year, therefore, was completely rounded off in congenial work and healthful recreation.

Simpson was one of the most unobtrusive of men and quite willing to efface himself for the advantage of others, although promptly and ardently resenting any slight offered to the department to which he belonged. He was of an even, calm temperament. His firm and definite religious convictions permeated absolutely his whole life. He had the enviable faculty, due to his wonderful belief, *aequanimis in arduis servare mentem*. To those of us who knew

him this was not a mere temperament, but a fixed belief in his Christian faith. Those who did not know him well were apt to think that he was somewhat austere and looked on the serious side of life too completely, but those of us who did know him knew very differently. No one was of a more kindly disposition, more disposed to take the charitable view of everything, and more pleased to enter into all the amusements and pleasures of those with whom he associated. This was an exceptionally charming characteristic of his.

During the long period of his connexion with the Obstetrical Society of Edinburgh he was three times its president, and there he ruled supreme. He seldom missed a meeting, and his remarks were always felicitous and peculiarly encouraging to the younger men. His attendance at these meetings was with him a religious duty.

His last appearance as a university professor was when he delivered the Promoter's address at a summer graduation, and a more beautiful, chaste, modest, and interesting piece of personal reminiscence it would be difficult to imagine.

Although, when he resigned his charge, he was over 70 years of age, he remained till his death in spirit, temper, and habit, one of the youngest and most active of men, and, indulging his great love of travelling, paid a visit to India.

He had a most comprehensive knowledge of the literature of obstetrics and gynaecology, and was deeply read in all departments of their science and art. He could, with the greatest ease and shortest notice, give references to the most abstruse and out of the way matters. He was an omnivorous reader and a close student, but unlike most, he had no favourite chair in which he sat, nor any favourite desk at which he wrote, nor any favourite room. His powers of application were such that he could read and write anywhere and at any time. It will always be a matter for regret that with his exceptional acquaintance with the literature and practice of his art, he did not produce a textbook, because such a volume produced in his fascinating and attractive style would have been a permanent asset. But he, like his great predecessor, did not care for the drudgery of that work, and his writings are, therefore, to be found scattered in various journals, and the papers he has left us are models of what such papers ought to be—concise, clear, and scrupulously accurate.

Sir JAMES AFFLECK writes:

It is hard indeed to realize that that bright and kindly spirit, with whom I had been holding friendly converse a few hours before, should have been so swiftly and tragically snatched away. Despite his 80 years, "his eye was not dim nor his natural force abated" in any direction (save for the infirmity of deafness), and he looked and walked as if there might yet be many more years in store for him.

It will fall to others to refer more specially to his professional merits which gained for him such an eminent position in his own department, as well as to his intellectual gifts and accomplishments. Relinquishing professional work at the age of 70, when he was admittedly at his best, his interest in medical science and progress never waned, but was keen to the last, while his activities in the domain of philanthropy and Christian work were unceasing.

His was truly a full life, and a fruitful one—fruitful in the many lives made better by his influence, his example, and his constancy; while his sympathies with every cause bearing upon the welfare of humanity found expression alike in his advocacy and his beneficence.

To those who are this day mourning his sudden end it comes as a solace to hear from so many lips the words, "He was a good man if ever there was one," and to feel that this worthy and noble life leaves so fragrant and enduring a memory behind it. Would that there might be an increasing number of such lives in our ranks!

Dr. ROBERT WISE (Stamford Hill, London, N.) writes:

I had the great honour of acting for one year as class assistant to Sir A. R. Simpson in the University of Edinburgh. I shall never forget his great kindness and hospitality. I last met him, hale and hearty, at the Royal Society of Medicine when he read his paper on Jean Astruc. I beg to add my humble tribute of praise to his true goodness and to his greatness as an obstetrician, gynaecologist, and physician.

SIR THOMAS BOOR CROSBY, KT., J.P.,

LL.D., M.D. ST. AND., F.R.C.S. ENG.

SIR THOMAS BOOR CROSBY, the first doctor of medicine to become Lord Mayor of London, died at the age of 86, on April 7th, at his residence in Gordon Square, after a short illness.

He was the son of a Lincolnshire farmer, and was born in 1830, at Gosporton, near Spalding. Apprenticed to a local surgeon, as was the rule in those days, he afterwards studied at St. Thomas's Hospital, and took the diplomas of M.R.C.S. and L.S.A. in 1852. At St. Thomas's Hospital he filled the appointments of house-surgeon and demonstrator of anatomy. He became F.R.C.S. Eng. in 1860, and two years later M.D. St. Andrews. After leaving the hospital he joined an old-established and very well-known firm of practitioners in Fenchurch Street, E.C., and his connexion with the City of London continued to the end of his long life. He became a member of the Common Council for Langbourn Ward in 1877, and alderman for the same ward in 1898. He was sheriff in 1906-7, and was elected Lord Mayor in 1911. He was then in his 82nd year, and it was noted that he was not only the first doctor of medicine but the oldest citizen to receive that office. His daughter acted as Lady Mayoress, and was associated with him in carrying on the many professional and social duties of the office. His term was distinguished by the assembly of provincial mayors and provosts at very short notice on the occasion of a serious coal strike, and by the raising of £450,000 for the *Titanic* fund. He attended, as Lord Mayor, at the funeral of Lord Lister on February 16th, 1912, at Westminster Abbey, following the pall-bearers in company with the Lord Provost of Edinburgh.

He early became a member of the British Medical Association, and was at one time a member of the Council of the Metropolitan Counties Branch. He showed great interest in the work of the Association in many ways, and it was largely due to him that the then Lord Mayor gave a reception to the members attending the annual meeting in London in 1913. In acknowledging a vote of congratulation from the Council of the Metropolitan Counties Branch on his election as Lord Mayor he said: "I am glad that my appointment to that office is a source of gratification to my medical brethren." There is no doubt that he valued his election largely because it reflected an honour upon his profession. He was at one time president of the Hunterian Society, before which he delivered, in 1871, the annual oration on "Modern Medicine"; he was also a member of the Senate of the University of London. He received several foreign Orders, including that of the Legion of Honour of France, of the Crown of Russia, St. Olaf of Norway, Dannebrog of Denmark, and the Rising Sun of Japan.

Sir Thomas Crosby was kindly and courteous. To the last he walked, spoke, and thought like a young man. He ascribed his phenomenal juvenility as an octogenarian to moderation, but also to his custom of ensuring a right amount of sleep. He taught that if a man lost his fair share of slumber one night he should never neglect to make up for it on the next night.

A memorial service was held at All Hallows Church, Lombard Street, on the afternoon of April 11th, when the funeral took place at Kensal Green. The Lord Mayor and Sheriffs attended in state, together with the members of the Court of Aldermen and many members of the City Corporation, including the representatives of Langbourn Ward.

TOM BATES, L.R.C.P., L.R.C.S. ED., M.R.C.S. ENG.,

CONSULTING SURGEON, WORCESTER GENERAL INFIRMARY AND WORCESTER OPHTHALMIC HOSPITAL.

Dr. TOM BATES, when just completing fifty years of practice, died of influenza on April 3rd at his old house in Foregate Street, Worcester. He had retired from active practice in 1913 and taken a residence elsewhere, but when his two sons and successors undertook military duties he resumed active work, and unfortunately the inclement weather which prevailed during the last week in March proved fatal to him. Born at March in Cambridgeshire, Dr. Bates received his education in Glasgow and Paris, took the diplomas of L.R.C.P. and S. Ed. in 1866, and that of M.R.C.S. Eng. two years later. He became associated with the eminent surgeon, Mr. Carden, and

later with Dr. Woodward, well known in Worcester. He soon acquired a large practice, solely through ability and force of character, as he was by nature very unassuming. He was not only a dexterous operator but was among the first to understand and practise the treatment by hot water of the commoner gastric disturbances due to errors of diet. For nearly forty years Dr. Bates undertook the only public work which was really to his taste—namely, the honorary surgeoncy of the Worcester General Infirmary, resigning in 1909, when his colleague, Mr. T. P. Gostling, observed that if ever the hospitals came on the rates they would never get such good service as they had received from Dr. Bates. Dr. Bates also held for a very long period the post of honorary surgeon to the Worcester Ophthalmic Hospital. He was a member of the British Medical Association, and when the jubilee meeting was held in Worcester in 1882 he served as secretary to the Section of Obstetric Medicine.

When, at the age of 70, Dr. Bates was about to retire and the infirmary found itself without a house-surgeon, he cheerfully volunteered to do the work, but then his colleagues insisted on sharing the responsibility. A year later he once more assisted the infirmary in the same way. When the war came he undertook, as above noted, his two sons' practice, which, unfortunately, proved too much for his physical powers.

Dr. Bates, a deeply read man, possessed a good knowledge of the French language, and was remarkable for his wit. A good cricketer in his youth, he was also a keen billiard player. He married a Malvern lady, by whom he had four children—two daughters and two sons. Both these sons, Dr. Mark Bates and Dr. Tom Bates, jun., have undertaken military duties. The funeral took place on April 8th at St. Nicholas's Church and Astwood Cemetery, and was attended by numerous members of the profession and patients, and by convalescent soldiers, and nurses from the infirmary.

THE profession in the West of Scotland has suffered severely in recent months by the death of some of its active and well known members, and the name of Dr. WILLIAM GRANT MACPHERSON of Bothwell has now to be added to the list of those who have gone. Carrying on his usual duties till he was taken suddenly ill on the evening of March 29th with what proved to be pneumonia, he passed away during the early hours of March 31st. He was a "son of the manse," his father being the minister of the parish of Canisbay, Caithness, the most northerly parish on the mainland of Scotland. There he received his early education. He entered upon the study of medicine at the University of Edinburgh, where he graduated M.B., C.M. in 1888. In the same year he went as assistant to the late Dr. Bruce Goff of Bothwell, and eventually became a partner in the firm of Goff and Macpherson. His sterling qualities as a man and as a physician were highly appreciated, and he practised his profession with much acceptance. He was greatly beloved by a large circle of patients throughout the Lower Ward of Lanarkshire. He gave much of his time and energy to the promotion of the honour and interests of the profession. Following the example of his late principal, he was an enthusiastic and loyal member of the Association, being at the time of his death a member of the Scottish Committee. He was also Chairman of the Local Medical and Panel Committee and a Member of Council of the Medical and Dental Defence Union of Scotland. In all of these offices his services were highly valued, and he was personally greatly esteemed. His unexpected and comparatively early death has caused pained surprise and sorrow to his friends and colleagues. He leaves a widow to mourn his loss, and for her the deepest sympathy is felt.

THE LATE DR. WILLIAM EVERETT.—Captain J. J. Harper Nelson, I.M.S., writes from India as follows with reference to Dr. Everett, whose death in consequence of the torpedoing of the ss. *Persia* on December 30th, 1915, was noticed in the JOURNAL of January 15th, p. 109:

The manner of his death was tragic, but filled one with admiration. I was a passenger on the *Persia*, and had been allotted a place in his boat in case of necessity. When the torpedo struck the vessel we all gathered opposite our boats. Our boat was the foremost on the port side. The *Persia* heeled

over to this side, and as starboard boats could not be lowered women and children were all directed to cross to the port side. Dr. Everett was at his place, and one has a vivid remembrance of his calm bearing under difficult conditions. He was very busy assisting ladies and children to remain upright on the sloping decks. The vessel suddenly rolled over on to its side, and Dr. Everett was unable to get clear of the ship. During the voyage I had got to know him fairly well, and I was impressed with his quiet, dignified bearing, sound professional knowledge, and keen insight into human nature. Men and women were to him not only patients but objects of character study, and his experiences as a ship's surgeon were consequently of absorbing interest. He was an excellent type of ship's surgeon, and his death is much to be lamented.

THE death took place at his residence, Askeaton, co. Limerick, on March 29th, of Dr. P. C. O'BRIEN, resident medical officer of that district. Dr. O'Brien, who was in his 70th year, was for many years medical officer of Askeaton Dispensary District, and his services were greatly appreciated by the public. Some years ago he was appointed a magistrate for the County of Limerick.

DR. G. H. ANDERSON died on April 10th at Loftus-in-Cleveland, after having been associated for over half a century with the district. A native of Aberdeenshire, he was educated at the grammar school in the city of Aberdeen, and graduated M.B. and C.M. of the University in 1865 and M.D. in 1867. He settled at Eston in North-East Yorks, but in 1868 went to Loftus, where he continued in practice down to seven years ago. Dr. Anderson devoted much time to local public affairs and took special interest in sanitary problems, the provision of an isolation hospital in his district being mainly due to his advocacy of an institution of that type.

PROFESSOR GILBERT BALLET, who died on March 17th, was one of the foremost specialists in mental disease in France. He was born at Ambazac (Haute Vienne) on March 29th, 1853. He began the study of medicine at Limoges but soon migrated to Paris, where he became *chef de clinique* under Charcot in 1883. He was appointed physician to the hospitals in 1884, becoming *agrégé* in 1886 and professor in 1907. For two years he lectured on the history of medicine, and in 1909 found his right place in the chair of mental diseases. He was president of the Congress of Alienists and Neurologists of France and French-speaking countries in 1901, and of the French Congress of Medicine. In 1912 he was elected a member of the Academy of Medicine, in the work of which he took a very active part. In 1914 he drew up a scheme of reform of the French lunacy law of 1838, and in 1915 he was reporter of a commission appointed to study the regulation of the sale of alcoholic liquors. Ballet was an ardent advocate of measures for the promotion of temperance. He contributed largely to medical literature. His most important works are lectures on psychoses and nervous affections, and a treatise on mental pathology.

PROFESSOR LÉON LABBÉ, who died recently, was born at Merlerault (Oise) on September 29th, 1832. He graduated at the Paris Faculty in 1861, became *agrégé* in 1863 and surgeon to the hospitals in 1864. For more than thirty years he was one of the leaders of French surgery. Many years ago his name was brought prominently before the public by his successful removal of a fork from the stomach of a man who had swallowed it; the case was known as that of *l'homme à la fourchette*. Labbé was the author, in conjunction with Coyne, of a treatise on benign tumours of the breast and of a number of other writings on surgical subjects. He was a member of the Institute of France and a very active member of the Académie de Médecine. He was a Commander of the Legion of Honour. Labbé retired from professional life in 1905 and entered the French Legislature, becoming Senator for the Orne and President of the General Council of the Department. Among those present at the funeral service, which took place at the Church of Saint Augustin on March 24th, were a number of representative men in science and politics.

Professor CHARLES GIRARD of Geneva, one of the leading surgeons of Switzerland, died on March 4th in his 67th year. He was born at Renan in the Val de Travers, and studied medicine at Berne, Tübingen, and Freiburg-im-Breisgau. He took his degree at Berne in 1872. He served during the Franco-Prussian war under Professor Lücke, then professor of clinical surgery at Berne. In 1872 Lücke was appointed head of the surgical clinic at Strassburg and Girard became his chief assistant. That position he held till 1875, when he returned to Berne; he became *privat-docent* in surgery, and in 1904 he was invited to succeed G. Julliard in the chair of clinical surgery at Geneva. He was the author of numerous papers on surgical subjects, and had been elected president of the Société Suisse de Chirurgie on the very day of his death.

Medical News.

THE offices of the BRITISH MEDICAL JOURNAL and of the Association, including the library, will be closed from Thursday evening, April 20th, to 10 a.m. on Tuesday, April 25th. The library and offices of the Royal Society of Medicine will be closed from Thursday, April 20th, to Tuesday, April 25th, both days inclusive.

SIR ALMROTH WRIGHT has been elected a foreign associate of the Paris Académie de Médecine.

AT the meeting of the Royal Microscopical Society at 20, Hanover Square, W., at 8 p.m., on Wednesday next, Professor Benjamin Moore will read a paper on early stages in the evolution of life.

DR. GIUSEPPE SERGI, Professor of Anthropology in the University of Rome, has just completed his seventy-fifth year. In honour of the occasion the Roman Anthropological Society has decided to publish a volume of original memoirs.

THOUGH a large number of soldier patients are receiving free treatment at the brine baths at Droitwich, the arrangements for dealing with ordinary cases are in no wise affected. We are asked to make this statement because it is said that some medical men are under the mistaken impression that the Droitwich baths have been given over entirely to military patients.

A MEETING of representatives of public hospitals in London and the provinces and of matrons and nurses was held on April 7th at St. Thomas's Hospital to consider the proposal to found a college of nurses. The Hon. Arthur Stanley, M.P., who was in the chair, said that the answers received from the governors of hospitals and nurses' training schools, and matrons, had convinced the promoters that they were working on the right lines. Several conferences had been held with representatives of societies which advocated State registration, and there was practical agreement that three fundamental principles must be adopted—State registration, a uniform curriculum, and a one-portal examination. It was proposed that the college should have a council of thirty members and a consultative board. The main object of the meeting was to ask those present to ensure that the board was representative of all branches of the nursing profession in Great Britain and Ireland. It was hoped to establish boards in Scotland and Ireland at once. A second meeting will be held next month.

WE have received the new number for April of the *Craigleith Hospital Chronicle*. It has, unfortunately, to record the death of Miss Annie Paulin, who had been intimately associated with the hospital since August, 1914, and who was also the first editor of the *Chronicle*. Dr. J. A. MacDougall continues his story of some Scottish regiments, the present instalment dealing with the Cameronians. There are some jokes, but not so many as usual, and a set of excellent verses, "Sworn Brothers All," by Henry Johnstone. We are indebted to Miss M. Anderson of Edinburgh for the gift through the editor of the *Chronicle* of the first two numbers. By this gift the file in the Library of the British Medical Association is completed to date. The *Gazette of the 3rd London General Hospital*, Wandsworth, celebrates the attainment of the age of six months in its number for April. Corporal Irving displays his versatility by imitating Mr. Nevinson, who contributes another excellent futurist drawing, this time "the driver of the ambulance." There are a good many other caricatures and some photographs. The *Norfolk War Hospital Magazine* has made its first appearance this month. The hospital has just celebrated its first birthday, but it occupies a building which has celebrated its centenary, and of this there is a photograph, among other illustrations.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

M.O. writes: In a munitions factory the employees have to dip their hands in hot water and also in 25 per cent. sulphuric acid, with the effect that the skin becomes cracked in places and red and inflamed in others, while the clothes in contact become ragged and tear readily. Can any treatment for the hands be suggested, and any particular clothing which might be useful?

LETTERS, NOTES, ETC.

METRIC PRESCRIBING.

DR. W. W. HARDWICKE (London, S.W.) informs us that the manager of a panel pharmacy recently refused to dispense a metric prescription on the ground that it was "written in French," whereupon Dr. Hardwicke wrote to the Secretary of the London Insurance Committee, who informed him that "a chemist on the panel is required to dispense prescriptions written in metric as well as those in which imperial weights and measures are used." This is, of course, the case. In the *British Pharmacopoeia* for 1914 the metric system is employed for all pharmaceutical and analytical computations, and it is stated in the preface that "the metric system has also been employed for the specification of doses, in the expectation that in the near future the system will be generally adopted by British prescribers. . . . As a transitional provision doses have also been expressed in terms of the imperial system."

FASTING TREATMENT FOR DIABETES.

DR. F. S. ARNOLD (Berkhamsted) writes with reference to the fasting treatment for diabetes discussed in the *JOURNAL* of March 25th: The fasting treatment in diabetes is not new, nor was it introduced by Dr. F. M. Allen. It has been practised and ably advocated by Guelpa of Paris for a good many years past. His work, *Autointoxication et Désintoxication*, in which the method is described, appeared in 1910, and my translation of it, bearing the actual title, *Fasting in Diabetes*, was published in 1912, and is now out of print. The "Guelpa method" in the treatment of diabetes has been the subject of many discussions of great interest at the meetings of the great French medical societies; it is fairly widely known, even to the lay public, in this country and in America; and, unless I am mistaken, it has been described and discussed in your columns a good deal further back than two years ago, when, according to the statement in your leading article, the fasting treatment was "introduced" by Dr. F. M. Allen.

INCREASED FEES.

M.D. writes: Would it not be well if a general notice were issued by the medical profession that medical fees have had to be increased? The reason for the increase is obvious, but the difficulty of the practitioner having to explain to his old patients the enhanced rates would be avoided.

PAIN AT ROOT OF NECK AND CARDIAC IRREGULARITY.

DR. D. OWEN WILLIAMS (Glandovey) has noted this condition in a woman aged 59. The stethoscope detected marked local pulsation and coupled beats corresponding to the heart sounds. Under appropriate cardiac treatment the pain passed away within four days, the heart sounds becoming normal. The patient had recently been subject to worry, and suffered a few years ago from albuminuria, which had entirely disappeared.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Observations

ON THE

TREATMENT OF GUNSHOT WOUNDS OF THE SPINE.

BY ALFRED J. HULL, F.R.C.S.,

MAJOR, R.A.M.C., BRITISH EXPEDITIONARY FORCE, FRANCE.

WHEN considering the place in the theatre of war at which spinal injuries should receive operative treatment it is necessary to weigh the advantages of early operation, which will limit the spread of septic infection and relieve the central nervous system of deleterious pressure, against certain disadvantages. These injuries require careful examination, and in some cases prolonged observation, before they are submitted to operation; a specially trained staff is required for their operative and after treatment. It is usually considered desirable that the patients should remain in the hospital in which they are operated upon for a considerable time. I think it is extremely doubtful that transport will be more injurious after an operation than before it. Of one thing I am convinced, and that is that the relief from pain which follows successful laminectomy places the patient in a much better position to withstand the strain of the journey. It is inevitable that, with the exception of certain conditions in siege warfare, when special units can be organized for particular branches of surgery, the treatment of these cases will have to be relegated to the base hospitals.

The following case is not without interest from the fact that the missile was removed from a portion of the vertebrae inaccessible by laminectomy:

CASE I.

Pte. C. was wounded by a rifle bullet, which entered the right loin 2 in. below the extremity of the last rib, and fracturing the transverse process of the second lumbar vertebra, lodged to the right of the body of the same vertebra. The patient suffered from severe local pain, which radiated down the branches of the lumbar plexus. There was partial motor and sensory impairment of the right leg. Five days after the injury a long incision was made in the right loin and peritoneum exposed by muscle splitting. A hand was then inserted by a retroperitoneal route and the fractured vertebra felt for as a guide to the bullet. A scoop was passed down the same track and the bullet removed. A counter-incision was made from the back to the site of the bullet and the cavity drained by "salt sac"—a tube made of gauze and bandage filled with common salt. Pain disappeared after the operation. Fourteen days later the wounds were healed, full sensory and motor control had returned, and the patient had entirely recovered.

Wounds of the spine may be extensive, the whole section of the cord being involved, and conductivity of the cord lost. Such cases present all the unfavourable phenomena associated with fracture-dislocation of the spine as met with in civil practice, together with the additional danger of septic infection. These cases are obviously unsuitable for operative treatment, but it is otherwise with many cases of spinal injury.

The following case reported by Captain Hepburn illustrates a type of inoperable cases complicated by concomitant injuries:

CASE II.

Wounded by a fragment of high explosive shell; was admitted about three days later with an irregular wound which would admit two fingers, situated about 2 in. to the right of the second lumbar spine. The wound was very septic, with extensive surrounding cellulitis. X rays showed the shell fragment lying in front of the left margin of the second lumbar vertebra, with a fracture of the body.

The patient became very toxic and extremely jaundiced, with severe abdominal pain and vomiting, and died ten days after being wounded.

At autopsy the shell fragment was found between the two layers of mesentery of the small bowel, which was extremely thickened. There was extensive retroperitoneal effusion of blood, a fracture of the body of the second lumbar vertebra, laceration of the top of the right kidney, but no laceration of the peritoneum and no injury of the liver.

Considering the results of spinal injuries as a whole, it must be admitted that they have not been encouraging, but it will probably be found that better will be obtained in the future. At the present time improvement has been noticeable in the results of treatment in these injuries. The cause of disappointment in the past was partly due to a lack of differentiation between hopeless cases and cases likely to benefit by operative treatment and partly to

delay in operation. Spinal operations, to be successful, must be performed at an early stage before any vital changes have occurred in the cord. The earlier circumstances allow the cases to be operated upon, the better will be the results. By delaying the operation, cases lose their chance of recovery in two ways—sepsis spreads, and pressure upon the nerve tissue causes vital changes in the cord. An early operation will remove the septic focus and relieve the pressure upon the nerve tissue, thus obviating the main causes of permanent nerve tissue lesions.

We have had many opportunities of witnessing the relief which follows the removal of a foreign body from the central nervous system. A foreign body, whether a missile or a depressed fragment of bone, exercises a striking effect upon the circulation of the brain and cord, and coincident with its removal the previously non-pulsating tissues begin to vibrate. Good circulation is essential to the recovery of injured tissue, and early operation affords the best chance of relieving the interference in an injury to brain and spinal cord.

We know that by operation planned to remove septic tissue and to relieve the pressure of fragments of bone or foreign bodies we can effectively deal with depressed compound fractures of the skull, and that by adopting the same principle we can excise a penetrating wound of the knee, remove infected bone, and obtain aseptic result. It would appear rational to apply the same principle to injuries of the spine, and, with certain reservations, this can be done. The spinal injury differs from the head injury in the greater susceptibility of the spinal cord and its lack of regenerative power. The small area of the spinal cord renders an injury to the cord of much more serious importance than an injury to the brain. An injured area in the brain may be recoverable, where an injury of corresponding size to the cord may destroy the whole section of the cord.

It would appear justifiable to operate upon spinal injuries when a foreign body is present and has been shown by x ray localization to be in an accessible position. Septic trouble is almost certain to follow a foreign body lodged within the spinal theca and its removal will not add materially to the patient's danger. Severe pain alone is occasionally a sufficient reason for operating.

The principal indications which make operative interference justifiable are evidence of some remaining conductivity of the cord, evidenced by the presence of some motor and sensory function in the part below the injury. Here the transverse lesion of the cord is incomplete, and the removal of pressure may be followed by great improvement. The circulation is restored and function is recovered.

CASE III.

Sgt. W. was wounded on October 24th and admitted to a base hospital on October 26th. There was a clean entrance wound at the back of the neck 2 in. to the right of the spinous process of the sixth cervical vertebra, and an exit wound in front, below the margin of the lower jaw on the left side.

The symptoms present were left hemiplegia and paralysis of the right arm, loss of sensibility on the left side, and hyperaesthesia of the right arm and foot. The presence of conductivity of the cord and the evidence of fracture of the fifth cervical vertebra were considered sufficient reason for operating.

A long incision was made over and down to the spine of the cervical vertebrae and the spinous processes cleared of muscles. Retractors were placed in the grooves on either side of the spines and the muscles retracted; the laminae were exposed and the fracture of the fifth vertebra discovered. The spinous process of this vertebra was fractured and the lamina on the left side was fractured near the articular process. The spinous processes of the vertebrae above and below were cut off. The right lamina was divided and the laminae of the damaged vertebra removed. A detached fragment of bone was found pressing upon the spinal theca. The dura was not lacerated and pulsed normally. The depressed fragment was removed and the wound sutured. The right arm recovered rapidly, and the following day sensation was normal. The patient suffered from considerable pain in the right arm after the operation. The operation wound healed by primary union.

The patient slowly recovered the use of his limbs, and three weeks after the operation had completely recovered, with the exception of partial paralysis of the left arm.

Cases of injury to the cauda equina have a much more hopeful outlook. The cauda equina bears a greater resemblance to the peripheral nerves than the spinal cord, and its nerve roots have been cut and sutured in animals, with complete recovery of function later. Tuffier

operated upon the first two lumbar roots, which had been divided by a bullet wound, and obtained perfect recovery.

The principal points by which injury of the cauda equina can be differentiated from injury of the cord are:

The position of the wound.

X ray may show a missile or fracture of the lower lumbar vertebrae.

Asymmetry of the symptoms.

Severe pain.

Pain and hyperaesthesia are indicative of injury of nerve roots rather than cord. Abolition of the deep reflexes points to a lesion of the nerve roots, either the efferent or afferent fibres being injured. The reflex centre in the cord may be injured in some cases, but the loss of conductivity will then be complete. Limitation of symptoms to a small portion of the segments of the lumbar-sacral region denotes a caudal lesion. A rapid increase of symptoms from segment to segment will denote a medullary lesion. A slow involvement of additional segments will point to a caudal lesion.

GENERAL CONSIDERATIONS AS TO TREATMENT.

Three lines of treatment are indicated—prevention of sepsis, removal of gross pressure upon the spine, and the prevention of complications which threaten life.

The most dangerous complication associated with spinal injury is septic infection of the genito-urinary tract, and this can usually be prevented by adequate care in the passing of catheters and by the use of urinary antiseptics and twelve-hourly lavage of the bladder. A solution of quinine sulphate, 1 or 2 grains to the ounce, has been recommended for this purpose. It is important that a catheter should be passed when the patient arrives at or leaves a hospital, and that instructions be given for the passage of this instrument during transport. The risk of sepsis is not added to by irrigation of the bladder once it is necessary to catheterize.

The following classification of injuries may be used from the point of view of treatment:

1. Injuries which have perforated the spinal theca.
2. Injuries which have not perforated the spinal theca.
3. Concussion of the spinal cord, which may be produced by the passage of a bullet through the vertebrae without actual pressure of the missile or bone fragment.

A trauma of the spinal column, even of a comparatively slight nature, may produce injury to the cord itself. The differentiation of concussion from organic injury has an important influence on treatment. A bullet passing through the body of a vertebra or merely touching one of the processes may produce concussion of the spine, presenting symptoms almost indistinguishable from an organic lesion. Neurologists rely mainly upon the improvement of the symptoms when distinguishing between the two conditions.

In severe concussion, paralysis of the body below the lesion takes place, the reflexes are lost, sensation is diminished, and the sphincters are paralysed. The chief signs by which the lesion can be differentiated from pressure upon the cord are as follows:

The transient nature of the symptoms; soon after the injury the patient begins to recover and there is a gradual return of function.

The symptoms usually correspond to those of a complete transverse lesion, and there is a complete loss of conductivity of the cord.

An x-ray examination will be negative.

The careful examination of the nervous system, the observation of the cause of the symptoms, together with an x-ray examination, will usually differentiate cases of concussion from cases suitable for operation, and prevent an unnecessary operation being undertaken. In some cases the diagnosis will only be made in the course of an exploratory operation. In cases in which the symptoms are practically indistinguishable from gross injury, an operation would appear to be justifiable on the grounds that it will do no damage and waiting will inflict irreparable damage upon cases suffering from the effects of pressure. Moreover, when a bullet has caused concussion, it has in all probability depressed bone also.

Pressure upon the Spinal Theca by Missiles, Depressed Fragments of Bone, or Extra-dural Haemorrhage, without Perforation of the Theca.

Here the outlook is most hopeful if the operation is performed before the pressure has caused irreparable damage to the nerve tissue. Laminectomy should be performed, and the missile or depressed fragments removed.

Complete recovery occurred after the removal of a shell fragment which had fractured the laminae of the fifth cervical vertebra, and depressed bone to the extent of half an inch square. Signs of recovery began to appear the day after the operation. The patient left for England with complete recovery of function.

Spinal Haemorrhage.

Haemorrhage may be produced by indirect violence, such as fracture of the body of a vertebra by a high-velocity bullet, or by direct injury to the theca by a missile or bone fragment.

Extra-dural haemorrhage or haemorrhage into the spinal theca may occur, and both conditions may be present in some cases. Cases of haemorrhage without other spinal lesions, such as concussion or pressure on the theca by foreign bodies or bone, are rarely seen, but haemorrhage in a degree sufficient to cause symptoms of pressure is often present with other lesions. In one case, operated upon for a bullet wound in the lower dorsal region, there was paralysis of both legs and of the sphincters; signs of conductivity of the cord were evidenced by the presence of sensation below the injury. Laminectomy was performed and a small fragment of bone discovered pressing upon the front of the cord. The dura was not lacerated and was pulsating feebly. When retracting the cord to remove the fragment of bone, a considerable amount of clot was squeezed out of the spinal canal, and at once the dura began to pulsate normally.

The treatment of spinal haemorrhage will usually form part of the treatment undertaken for the relief of pressure from some other cause. Cases in which spinal haemorrhage played an important clinical part have been rare in our experience. The optimistic view that haemorrhage into the spinal theca will recover spontaneously is more than doubtful, and such cases would appear suitable for exploration.

Injuries to the Spine with Penetration of the Dura.

The condition is comparable to that of depressed fracture of the skull, with particles of indriven bone penetrating the cranial meninges and lacerating the brain. Sepsis is exceedingly likely to extend to the spinal meninges along the bullet track and depressed bone. The most excruciating pain may be caused by depressed particles of bone, and the advance of sepsis mercifully ends the patient's suffering by causing spinal meningitis.

The only successful treatment is the early removal of the peccant fragments. Expectant treatment allows the patient to run risks out of all proportion to the risk of an operation. If spinal sepsis does not end the patient's sufferings an infection of the genito-urinary tract usually occurs, and in those rare cases in which the patient survives these dangers he often remains a hopeless paralytic.

Undertaken at an early stage by specially experienced operators, the surgical treatment of this condition should prove if not brilliant, at least a means of saving a fair portion of the victims.

It is of the utmost importance that the operation be carried out under a local anaesthetic, or shock, haemorrhage, and chest complications will levy their toll. The operation begins as an ordinary laminectomy operation, except that if the bullet track be accessible it should be excised. In some cases the results can be obtained without any bone-cutting at all, the fractured lamina being merely removed with forceps and scissors.

Circulatory disturbances are at work in these cases, the pressure of the fragments upon nervous tissue exercising an untoward effect upon the circulation of the central nervous system. The importance of the early relief of this interference with the circulation must be fully recognized if a favourable result is to be obtained. The delicate nerve tissue of the cord rapidly receives irreparable injury from pressure, the patient is worn out by pain, and septic infection extends as a result

of delay in operation. Operative treatment may be contra-indicated in some cases. Severe injury to other organs and total loss of conductivity of the cord will usually negative operative treatment.

Foreign Bodies within the Spinal Theca.

In addition to any damage the missile may have inflicted on the cord or cauda equina, the danger of sepsis makes the injury most serious. The missile will almost certainly have carried septic matter into the wound, and will form a septic focus within the theca. Early removal of the missile gives the patient his only chance if the missile be septic.

The results of removing septic missiles from within the cranial meninges is sufficiently satisfactory to make such operations on the spine hopeful if performed within a reasonable time of the injury. In one case a shrapnel bullet was removed from within the spinal theca in the lumbar region seven days after the injury. The patient was paraplegic before the operation, and great improvement in motor power had taken place before he left hospital.

The interest of the following case lies in the fact that complete recovery followed an operation upon a septic wound complicated by a septic compound fracture in the vicinity of the spinal wound. The case appeared to be almost hopeless, as septic meningitis seemed almost certain to occur. In this case, as in all spinal cases, urotropine was administered from the beginning.

CASE IV.

Pte. M. was wounded in several places by fragments of high-explosive shell. Two fragments lacerated the skin over the fifth dorsal spine, fractured the spinal laminae, and entered the spinal theca. A larger fragment inflicted a large lacerated wound over and fractured the left scapula. Partial motor and sensory paralysis of both limbs was present, and the patient suffered from violent pains in the right leg. The bladder and rectum were normal. Five days after the injury the compound fracture of the scapula was in a most septic condition, and pus and cerebro-spinal fluid were exuding from the spinal wound. Two metallic foreign bodies were localized within the spinal canal. The septic compound fracture of the scapula was treated by dressing with gauze soaked with hypertonic salt solution, the dressing remaining in the wound, untouched, for four days. The perforating wound of the spine was excised, the track of the missile having been packed with gauze soaked with tincture of iodine. The laminae of the fifth and sixth dorsal vertebrae were exposed and a comminuted fracture of the fifth arch discovered; this and numerous depressed fragments of bone were removed. A laceration of the dura was present; a scoop passed through the laceration detected a metallic foreign body; this missile and some fragments of bone were extracted. The second foreign body could not be reached, so the laminae of the sixth dorsal vertebra were removed, exposing it; the remaining fragment was then removed from the spinal theca. Two small salt sacs were inserted down to, but not into, the spinal theca, and the muscles were drawn together by a catgut suture. The skin wound was partially closed. The spinal wound was well shut off from the septic compound fracture by impermeable material. The entire operation was performed under local anaesthesia.

The patient's limbs were massaged daily, and ten days after the operation he had regained complete motor and sensory functions. The spinal wound was dressed seven days after the injury, the salt sac came away quite easily, and the wound was afterwards dressed daily with 5 per cent. saline solution. A considerable amount of cerebro-spinal fluid escaped from the wound for a fortnight after the operation. The patient suffered from violent pain in his legs during convalescence.

Two months after the injury the patient was walking about completely cured.

Wounds of the Spine causing Total Loss of Conductivity of the Cord.

An irreparable injury has been inflicted upon the cord, and an operation will not lead to any improvement of the symptoms. These cases are comparable to the cases of fracture dislocation of the spine met with in civil practice. They are unsuitable for operative treatment. An exception to this may be made in cases in which the pain is so severe that an operation is worth undertaking for its relief alone.

Exceptionally, it may be possible to prolong a patient's life, although he is foredoomed to death, by undertaking an operation for the removal of sepsis.

INDICATIONS FOR OPERATION IN GUNSHOT WOUNDS.

Cases in which there is Evidence of some Conductivity of the Spinal Cord.—In all cases in which conductivity of the spine remains there is hope of improvement in the

functions. An operation will not harm the cases in which the damage to the cord is too extensive to allow of recovery, and will save the lives and functions of the slighter cases.

Pain.—The pain in some spinal lesions is so atrocious that an operation is justifiable, whatever the lesion of the cord.

CASE V.

Fracture dislocation of the first and second lumbar vertebrae, caused by the fall of a trench wall. Motor and sensory paralysis were complete with the exception of slight movement in the toes of the left foot. Retention of urine. The patient suffered excruciating pain. There was little hope of improvement in function, but a laminectomy was considered justifiable for the relief of pain. The pain was immediately cured by laminectomy, and considerable improvement in motor power resulted.

Operations upon Spinal Injuries.—The x-ray examination preceding the operation is of the greatest importance. A lateral as well as an antero-posterior plate is always necessary, and if a foreign body is present accurate localization must be carried out. The localization of the foreign body is so important and so difficult to obtain in this situation that special precautions must be taken. No reliance should be placed upon stereoscopic plates when used either in a stereoscope or by squinting. They are liable to represent a foreign body either deep or superficial to a known structure according to the preconceived idea of the observer. In the lumbar region the curve of the spine prevents the close application of a glass plate to the skin; a film should be employed in this situation. It is necessary to place beyond all possible doubt the level at which a foreign body lies. The surgeon must be able to attack the lamina concealing the foreign body with confidence that he is removing the right one. Unnecessary removal of the lamina and dangerous searching will be avoided if the following procedure be adopted:

Under local anaesthesia a deep silver suture is placed at the side of the spinous process of the suspected vertebra. The patient is then x-rayed and the wire left *in situ*. During the operation, whether the wire is next to the vertebra concealing the missile or not, it will be easy to identify the correct one, which if not opposite the wire is usually the one above or below. A similar method is to scratch the skin across the suspected spinous process, and lay a needle across the scratch before taking the x-ray plate. Some such precaution is to be recommended. Counting the vertebrae during an operation has caused doubt and difficulty even to experienced operators.

Shaving the skin area, cleansing with ether and biniodide, the application of a sterile dressing two hours before the operation, and painting the skin with iodine at the time of operation, has given satisfactory results. Local anaesthesia has usually been employed, in some cases combined with a slight degree of ether or chloroform anaesthesia. The use of local anaesthesia has been found to be so advantageous that other methods have been abandoned. The success of the operation depends largely upon its use. Several cases suffering from severe chest complications have had no ill effect from the operation. Either the prone or the lateral position may be employed; the prone position gives the better exposure of the vertebrae. When the lateral position is employed the lower leg is placed in the extended position, the upper leg is flexed, the knee being bent to a right angle, and a thick hard pillow is placed beneath the bent knee and leg. In this position the patient rests comfortably and firmly on his side. An incision is made in the middle line down to the spinous process. The incision should be a long one, about 8 inches in length. The retraction of the soft parts and exposure of the laminae are much facilitated by a long incision, and the whole operation can be carried out with greater ease. The spinous processes are then cleared on both sides by cutting downwards close to the spinous process, to the laminae through the whole length of the incision. With a pair of strong scissors the remaining muscles attached to the spinous processes are cut and cleared away. When the soft parts have been cleared from the spinous processes throughout the whole length of the wound it will be possible to pass a pair of retractors down to the laminae in the grooves on either side of the spine and retract the erector spinae muscles.

The vertebrae can now be examined; if a depressed fractured lamina is discovered, the spines of the fractured vertebra above and below are cut off and the fracture examined. In some cases the fracture involves the laminae at each side, and these can be removed when the ligamenta subflava have been divided.

The lamina of one side may be fractured, and it may only be necessary to divide the uninjured side, or both laminae being fractured they can be removed without cutting any bone.

The most difficult step in the operation is the division of the first lamina. The lamina must be removed as far as the articular process, but it is not necessary to commence the section at this difficult spot; the lamina may be divided nearer to the spinous process and the remainder of the lamina removed with bone forceps. There are three well-known methods of dividing the laminae, of which the use of the cutting bone forceps is probably the easiest and most convenient. A saw may be used either of the guarded pattern, or a Hey's skull saw. The cut is made with an inward direction in order to avoid the articular process, and the section is completed with forceps. The drilling or trephining method is carried out by cutting a hole in the middle of the lamina with a drill or burr, and completing the section with De Vilbiss or other suitable forceps. The entire division by forceps is rapid and sufficiently easy. Laminectomy forceps, Sargent's craniectomy forceps, or Jansen's bone forceps may be used. Whatever forceps are employed, the surgeon must be practised in the use of the instrument. With well-devised bone forceps the lamina may be bevelled until the edge is very thin and easily elevated. The spinal dura is separated from the lamina by tissue, and is not easily injured with ordinary care. The infiltration of the tissues with adrenalin solution, a long incision permitting easy retraction, and a good exposure of the laminae will greatly facilitate this difficult stage of the operation.

When the spinal canal is opened the condition of the fracture can be further investigated, detached fragments of bone or the missile may be discovered. The spinal canal will sometimes be found to be filled with effused blood, and a continuous stream of saline may be commenced at this stage. The dura is examined, and if uninjured and pulsating normally is not opened. If lacerations are present, depressed fragments of bone or missiles are sought for. The operation is completed by suturing the spinal muscles by one continuous catgut suture and suturing the skin without drainage. The wound is invariably painted with mastisol wound varnish.

Secondary infection and death from meningitis is very apt to follow drained laminectomy wounds when incontinence of urine or faeces is present.

At the conclusion of the operation, and for some days afterwards, the patient is placed flat on his back. The pressure upon the wound is advantageous.

In the dorsal area it is comparatively easy to explore the spinal canal anterior to the cord. One or two nerve roots may be divided with safety in this region and the theca gently retracted. The nerve roots are afterwards sutured with fine catgut. Operations for injury to the cauda equina have given the best results. Any division of the cauda which is discovered should be sutured. The probability of regeneration and recovery of function is considerable.

CONCLUSIONS.

1. The majority of cases of gunshot injury to the spine require excision of the wound and exploration at the earliest favourable opportunity.
2. The diagnosis is not so gloomy as past experience teaches.
3. Local anaesthesia is practically essential.
4. The administration of urotropine should be begun as soon after the injury as possible.
5. The presence of a missile together with severe pain are indications for immediate operation.
6. Accurate localization of foreign bodies is of the utmost moment. A lateral as well as an antero-posterior view is desirable.

THE TOXIC EFFECTS OF ETHYLHYDROCUPREIN ON THE EYE.

By GEORGE H. OLIVER, D.O.Oxon.,

HONORARY OPHTHALMIC SURGEON, ROYAL EYE AND EAR HOSPITAL, BRADFORD.

CONSIDERABLE interest has been aroused lately regarding the therapeutic value of the alkaloids and derivatives of cinchona, and attention has been drawn to this in recent numbers of the *BRITISH MEDICAL JOURNAL*.¹ In a paper by Morgenroth² and Levy³ on the chemo-therapy of pneumococcus infection, the process by which they arrived at the conclusion that the pneumococcus can be destroyed or rendered inert by quinine or its derivatives is described. They showed that in certain infections induced artificially by virulent strains of the pneumococcus the micro-organisms can be destroyed, and the lives of the majority of the animals saved by the administration of ethylhydrocuprein. Fränkel⁴ used this drug, which is a quinine derivative, in a number of cases of pneumonia, which was then epidemic in Berlin. In describing his results, he said:

As with the serum therapy of pneumonia, which does not promise much, so with ethylhydrocuprein. This does not appear to be the thing we want, chiefly because it produces a very disagreeable complication, which, though it occurs in a small number of cases, yet is so evident that the drug cannot be recommended for use in practice. This complication is the occurrence of amblyopia, which we observed in 14.3 per cent. of our cases. The single dose prescribed was 0.5 gram, and from 1 to 2.5 grams were administered internally daily. After we became aware of this effect of the drug we did not give above 2 grams a day. The amblyopia disappeared rapidly (two days) on stopping the drug. I have no doubt that, had we continued this treatment, permanent visual defects would have followed. You know that in simple quinine intoxication complete amaurosis occurs. Ophthalmoscopic examination showed well-marked narrowing of the retinal vessels, chiefly the arteries, with reduced visual fields. When at the worst, the patients were able to make out fingers at 1 or 2 metres only.

The complication here described has occurred in a case in which I am interested, but with disastrous results. In the early part of 1915 I was called in consultation to see a man, aged 40, who a month before was extremely ill with pneumonia. His medical man, with the consent of the consulting physician, prescribed ethylhydrocuprein in 5-grain doses, to be taken every three hours. The patient took in all 120 grains.

The day previous to the discontinuance of the drug the patient complained of roaring in the head, partial deafness, and a feeling as though a dark blind had been drawn over his eyes. He was so ill and difficult to understand that these symptoms were considered to be due to meningeal complications. The drug was stopped next day, when it was found that he was quite blind and could not distinguish light from dark.

I found that he had bare perception of light; the right pupil reacted very slightly to light, the left not at all. Pupils two-thirds dilated. Ophthalmoscopic examination showed that the vessels were reduced to fine threads, the arteries being made out with difficulty in the left eye; both discs were quite white. This was in February, 1915, one month after the commencement of the symptoms. I saw him again on March 11th, 1915. My notes are as follows:

Considerable improvement in vision; can find his way about inside and outside the house, and can distinguish such articles as a knife, fork, or spoon at three metres.

On April 3rd, 1915, there is much improvement; V. = R. $\frac{2}{6}$, L. $\frac{2}{6}$; reads J. 4 slowly; L. E. and C. R. J. 14; both fields very much contracted; pupils react to accommodation and slightly to light. Colour vision obliterated. Right disc not quite so white, but vessels still attenuated, more so in left eye.

On June 5th, 1915, V. = R. $\frac{2}{6}$, L. $\frac{2}{6}$. Ophthalmoscopic examination: Right eye, faint blush on temporal side of disc. Left disc quite white and vessels reduced to fine threads. Pupils both oscillate in a remarkable manner, synchronously, in day and gas light.

August 25th, 1915. V. = R. $\frac{2}{6}$, L. $\frac{2}{6}$; near vision = J. 4 c R. and L. Complains of severe pains in the back, which have troubled him more or less since convalescence set in. Attacks last a few days, during which visual acuity is considerably lowered and fields much more contracted, with immediate restitution to former level when pain ceases. Small coloured objects 2 mm. to 3 mm. in diameter not spotted, but with larger objects, such as postage stamps, red and green colours are easily named.

It is impossible to map out the colour fields (Bardley's sclero-meter); the patient is so uncertain of the boundary zone. Ophthalmoscopic examination: Discs as before; vessels, arteries, and veins have a well marked double outline, which is carried a considerable distance beyond the disc, and in one or two instances is more distinct than the blood column.

The most striking circumstance is the great improvement made up to June 5th, 1915, which one would have little expected, seeing that the vessels were so narrow and the discs so white, indicative of the destruction, from reduced blood supply, of a large number of ganglion cells in the retina, and the visual fields so much reduced, as shown in the accompanying charts.

I heard recently from the patient's family doctor that the improvement made was not maintained, and I asked the patient to come to my rooms, which he kindly did.

On February 5th, 1916, V. = R. $\frac{1}{2}$, L. $\frac{1}{2}$. Vision began to go down in November, 1915, and steadily declined until Christmas, when he could not see his food on the plate before him. In the second week of January, 1916, he began to improve, and has continued to do so up to date. Ophthalmoscope: Both discs now quite white with no trace of colour; details not discernible. Vessels seem to have increased in size a little, and a few very fine branches may be seen on the discs. Vessels in left eye are smaller than in right eye, and both arteries and veins have a double outline which extends far away from the disc.

Apart from these changes, the fundus is quite normal in

appearance. Pupils are dilated and contract very slightly to light and still oscillate. I am afraid there is little hope of this patient being able to earn his own living in the future.

That ethylhydrocuprein is a dangerous drug I have no doubt, and its internal administration is to be carefully avoided. It may happily be discovered that much smaller doses than those given heretofore will suffice to destroy the pneumococcus; indeed, it has been shown by Henry

F. Moore¹ in his experimental studies with this drug that "it inhibits the growth of and kills pneumococci *in vitro* in very considerable dilution," and that "the serum of rabbits which have been previously treated with a single dose of ethylhydrocuprein exerts a bactericidal action on, and later inhibits

the growth of pneumococci in the test tube." Known also by the name of optoquin, this substance has been used by ophthalmic surgeons in the treatment of serpiginous ulcer of the cornea. Some say it will cure a virulent ulcer in ten days, and others, including myself, have seen no special advantage in its use, while cases have been reported in which the instillation of a 1 per cent. solution of the drug has caused rapid destruction of the cornea.

SOME NOTES FROM THE BATTLE FRONT IN NORTHERN FRANCE.

By A. LAPHORN SMITH, M.D., M.R.C.S.ENG.,

LATE SURGEON-IN-CHIEF OF LADY EVA WEMYSS HOSPITAL; LATE TEMPORARY MAJOR R.A.M.C.; FORMERLY SURGEON-IN-CHIEF, SAMAHITAN HOSPITAL, MONTREAL, AND PROFESSOR OF ABDOMINAL SURGERY, BISHOP'S UNIVERSITY.

My experience has been gained in the military hospital established and maintained under ideal conditions by Lady Eva Wemyss near Soissons, and by frequent visits to the great receiving hospitals at Compiègne under Ligusard, Carrel, and Mencières. These hospitals were only a few miles behind the firing line.

In such a hospital as that of Lady Wemyss the conditions for the rapid healing of wounds were unusually favourable. The three most important elements of success in treating wounds we had there in abundance—sunlight, fresh air, and pure water—and we made use of them all to the fullest extent. Every bed in the hospital was carried out of doors at 10 a.m., and the patients remained out until sundown. The heavy dressings were removed, and only a light layer of gauze put over the wounds to keep out dust but to let the light in. Even the operating was practically out of doors, to the great advantage not only of the patients, but also of the surgeons and nurses. The bathhouse was outside of the hospital, so that the wounded entered the wards clean in body and clothing. They were induced to drink water by every possible means, generally in the form of Imperial Drink, made with a teaspoonful of cream of tartar and the juice of one lemon to the quart of boiling water, and sweetened with sugar or saccharine to taste. Many were suffering from rheumatism, arthritis, neuritis, and cystitis, and these were all given fifteen grains of potassium bicarbonate in a tumbler of lemonade; this makes a pleasant effervescent drink, containing citrate of potash. Sometimes they took their water at every meal, flavoured with

red wine, and at other times they had an abundance of beef-tea. When they had lost a great deal of blood and were unable to drink enough to replace it quickly, they were given large quantities of beef-tea by the rectum by slow continuous absorption, the reservoir being a douche bag lying at the foot of the bed, raised on blocks, so that the supply was only a few inches higher than the rectum. When thus introduced without pressure the rectum does not so easily rebel, but will, on the contrary, drink up enormous quantities of liquid. As every patient had received antitetanus injections, we did not have a single case nor did we have one of typhoid. There were no deaths and no amputations of limbs. We had several very high temperatures, which caused me a great deal of anxiety until, at Sir Joseph Godfrey's suggestion, I gave 10-grain doses of quinine. One case turned out to be tertian and another quartan ague.

In the morning we were awakened by the roaring of the guns, and soon after the wounded men began to arrive at the base hospital, already having had their wounds swabbed with 2 per cent. iodine at the field dressing station. Those who had fractures were put up in temporary splints, and then some thirty ambulances arrived from the subsidiary hospitals, so that by noon there was hardly a surgical case left. Carrel took many of the badly infected cases, or rather those in whom there was every probability of suppurating occurring. Mencières, the orthopaedic surgeon of Rheims, and chief of the Compassion Hospital, was allotted the bad cases of joint injury by shrapnel and bullet, requiring great operative skill or his "embalming" treatment. To the Lady Wemyss Hospital were allotted the compound comminuted fractures and many of the wounds and burns caused by shrapnel bursting at close quarters. By two o'clock the patients had been bathed, x-rayed, and in the operating-room. The x-ray machine was run by storage batteries charged by a small gasoline engine. The x-ray plates were held up before the operator, and each piece easily seen and removed. In many cases the fragment of shell was nearly a foot

away from the wound of entrance, so that in most of the cases a fresh incision was made over the spot where the bullet was located, and the long track through which it had travelled was cleaned, drained, and allowed to heal, which it quickly did. Most of the shrapnel wounds having been made from above downwards while the men were standing in the trenches, the shells exploding in the air, the fragments of steel were all situated much below the wound of entrance. To probe for the foreign body with a director in order to remove it with long forceps would be a mistake, for there would almost surely follow a collection of pus, since there is a little cavity containing small particles of clothing or mud. By making the opening at the most dependent part we can get the fragments out and flush the track and cavity with 1 in 4 hydrogen peroxide. In a few days the wound of entrance and the track will have completely healed, and the new wound, especially if it has been packed with iodoform gauze for the first day or two, will also have closed. Many of the patients went back to duty in ten days or less.

Many of the wounds were in the scalp, face, and neck, and it was evident that a light nickel steel helmet would have saved thousands of men from leaving the trenches. We called the attention of our Surgeon-General to the great number of scalp wounds, and soon after light steel helmets were provided in large numbers for the French soldiers, with truly remarkable results. While many were stunned, the helmets saved them from fractures of the skull and severe lacerations of the scalp, which would have kept them from the trenches for weeks or months. If the bullet had gone through the arm or leg, or muscles of the chest, shoulder, or buttock, a drainage tube with many windows was of the greatest advantage—first, by preventing the wound in the skin from healing too soon; and secondly, by preventing the pus from being absorbed. It is well to remember that even a teaspoonful of pus pent up without drainage or blocked by gauze packing may imperil a soldier's life; while ten times as much pus well drained will not even cause a rise of temperature.

Conservative Surgery.

No effort is too great nor time too long in order to save limbs as long as there is any life in them. A great many, even the great majority, of the badly damaged limbs may be saved, and eventually become very useful, without risking the patient's life. The collateral circulation of the leg can be well developed in a few hours after the femoral has been cut across. The limb should be kept warm, so as to dilate the arteries and capillaries. Also by elevating the bed at an angle of 45 degrees the venous blood will run back to the heart by gravity, and thus make it so much easier for the fresh hot liquid to keep the injured tissues from gangrene. With antiseptic surgery and antitoxins, patient but ever watchful waiting has taken the place of operative daring, but watchfulness is required to steer the patient through the surgical dangers. With a finger on the pulse and an eye upon the quantity of pus, and the effect of the loss upon the patient's face, we must be ready at a moment's notice to adopt Menci re's method, or the more dangerous method of amputation, leaving him in the one case with his own leg, and in the other with a wooden one. Every dressing should be weighed before and after its application to ascertain how much fluid the patient has lost (minus the amount evaporated). Pus consists of the great army of dead phagocytes killed by the microbes. It costs much blood to provide these phagocytes, and there is a limit to the number that the patient can furnish. So we supply him with at least iron phosphates and albumin to make up for what he is losing by his dead cells. A better way to estimate his loss is by a tube 2 ft. long; its upper end, with many windows, is placed for the whole length of the pus producing area and the other end in a white glass wine bottle attached by a wire around its neck to the frame of the bed underneath. If the wound be sealed hermetically, all the pus must pass into the tube through the windows and into the bottle. But as this end is much longer than the end in the wound the weight of the pus dropping into the bottle siphons the tiny particles as they are formed in the miniature battlefield, instead of being left until they accumulate enough to overflow. Carrol connects every drainage tube by a hollow copper wire with a vacuum pump, and a

column of mercury shows the degree of vacuum in every wound; 6 in. or 8 in. of vacuum is enough. The effect of this method of drainage is that, first, the temperature drops to normal because the ptomaines given off by the microbes are removed *pari passu* instead of being absorbed—ptomaines give temperature. Secondly, the pulse drops to normal. Thirdly, the burning and discomfort of the skin disappears because there is no wet gauze soaked in acid pus bathing it from one dressing to the next. Fourthly, the bills for dressings also drop. The pus goes into the bottle, which is weighed every twenty-four hours; the colour and consistence; as well as the weight, can thus be ascertained. If the dressing becomes wet, or the temperature goes up, the tube must be removed and cleaned. Otherwise there is no scientific reason for changing it every day. But the dressing of gauze paper is so cheap that we may change it every day; it can be sterilized the same as absorbent cotton. Another great advantage of the paper dressing is its lightness. A large package enough for a dressing only weighs an ounce and only costs a halfpenny. If my notes do no more than call attention to the wonderful absorbent paper, they will not have been written in vain.

Pus is full of phosphates and some iron, and a patient who is losing from 8 to 16 oz. a day cannot go on very long if these substances are not replaced. He becomes weak, develops neuralgic pains which demand morphine, and he dies from exhaustion, his heart growing weaker and weaker from want of food. The most digestible form of phosphates and iron are hypophosphites or glycerophosphates. The responsiveness of the cerebro-spinal system in many of the wounded, at least, has been weakened by nicotine. The bowels are stagnant, and the decomposing food gives out nauseous gases and poisons, and the stomach works feebly in digesting meat or casein. If an excessive tobacco smoker comes to us in civil life suffering from nicotine poisoning we give him comparatively large doses of nuxvomica, with remarkable results. If a wounded man who is poisoned even to blindness, of whom I have seen several, comes under our care his wound will heal in half the time if we get the nicotine out of him and stimulate the paralyzed trophic nerves with strychnine and electricity. If his wounds are suppurating profusely give hypophosphites, and if he has sudden spurts of temperature give quinine. As to antiseptics, I have great confidence in potassium permanganate, but I have seen excellent results from hydrogen peroxide and also from carbolic acid. I have personally put potassium permanganate to the most severe test possible, only after my confidence in it was absolute. I have been called in consultation to cases of puerperal septicaemia in the pre-rubber glove days, and when I had to perform several abdominal sections on the same day. I blackened my hands and arms the colour of mahogany with a strong solution of permanganate and whitened them in solution of oxalic acid, and then in the ordinary boric solution and alcohol; the cases all recovered.

When I had a dangerous infection of my hand I asked the Professor of Surgery of McGill to cut through the swollen tissue under cocaine and to fill the yawning crater with dry powdered permanganate, which carbonized the microbes, gangrenous tissue, and phagocytes alike. This was at 10 p.m., and by next morning I was saved. Permanganate has the great advantage that it is not a poison if used externally. While in Paris the chief surgeon of one of the great French hospitals asked me what I would suggest in the case of a soldier with gas gangrene whose foot he had amputated; the wound had not united at all; it fell open as soon as the stitches were removed. The odour was sickening. I suggested putting the foot into a rubber bag filled with a strong solution of permanganate for twenty-four hours. From the first moment, I learnt, there had been no more odour and the man began to improve.

Recently I was in charge of a case of carbuncle of the neck which poured out enormous quantities of acid pus which burned the surrounding skin and started a crop of subsidiary boils. The man was exhausted with pain and suppuration, and was going downhill rapidly. Under an anaesthetic I made a 2-inch cross incision and plunged my gloved finger into the cavity as far as the second joint. A hole for drainage was made at the most dependent part, and a wick inserted. Then a teaspoonful of finely powdered

permanganate was poured into the cavity, which had been thoroughly curetted to remove the pyogenic lining. The powder was pushed into every crevice with a piece of cotton on a forceps and with the finger, and some gangrenous skin and cellular tissue removed with scissors, and the wound was packed with a strip of gauze. It was left alone for a few days, during which the man rapidly improved, and when the wound was washed out there was a healthy pink granulating surface, but almost dry. At the end of ten days he was out and about.

Mencièr's Method of Embalming.

One of the greatest pleasures of my stay in France was that of assisting Mencièr at these operations at the Hôpital de la Compassion. I may describe one of the many cases I saw with him.

A young farmer from the south of France was shot through the ankle by a rough piece of cast steel shrapnel. Pieces of his shoe and sock were carried through and left there, although the steel went through. As he had been standing in the same wet and dirty socks for weeks in the trenches the wound was badly infected. The tibia, fibula, and scaphoid were shattered into many fragments, some living, but most of them dead. One collection of pus formed after another, and the poor fellow was so exhausted with pain and suppuration that he continually begged to have his leg removed. No sooner was one abscess opened and drained than another formed, so that at one time there were four drainage tubes traversing the joint at various angles. Mencièr thought the leg might be saved, and the man was transferred to his hospital for operation. The operation was done very quickly under spinal anaesthesia. A tourniquet was applied around the thigh, so that it was bloodless. The antiseptic precautions were perfect. The operator made a 9-inch incision, which was held open by powerful retractors while he removed the suppurating fragments and curetted the cavity with a sharp spoon. With a cold chisel and mallet he cut away the ragged ends of the tibia, fibula, and tarsus. When he had finished there was a cavity which more than held 8 oz. Mackintosh was fastened to the edges of the skin, and the cavity after being thoroughly dried was filled with pure carbolic acid, which remained there one minute by the watch. This was removed with swabs of cotton, and then the cavity was irrigated with 5 to 7 pints of strong alcohol. Again the cavity was dried and then irrigated with the embalming fluid, consisting of alcohol, ether, iodoform, guaiacol, eucalyptol, and balsam of Peru. The ether acts as a vehicle to carry the antiseptic substances into every corner. After this a permanent dressing was applied, consisting of strips of gauze soaked in solution A, which is ten times stronger than solution B. This dressing is removed twice daily for seven days. The phenolized wound, which appears whitish directly after the carbolic acid is applied, becomes once more red under the influence of the lavage with alcohol. Next day the wound looks more or less blackened with the acid, but it is dry and clean and has lost the nauseous characteristic odour of gas gangrene.

Mencièr claims that most antiseptics act only on the surface, while phenolization acts in the depths of the tissues where the *Bacillus perfringens* becomes harmful.

I can testify to the fact that Mencièr saved many limbs by his method. It is easy to learn and carry out, although rather expensive on account of the large quantity of ether used. Whether we could not obtain equally good results by the deep disinfection of wounds by potassium permanganate, either in powder or in strong solution, I am not prepared to say.

Ulcers and Burns.

Great improvement in the healing of large ulcers or wounds of the feet and legs can be obtained by raising the foot of the bed on two chairs or blocks, so that the wound will be absolutely higher than the patient's nose. Zinc oxide ointment on oilcloth, not oilsilk, but cheap white table oilcloth, is the best treatment for extensive burns such as we had a great many of, due to the explosion of bombs a few feet distant. Some of the men had their trousers burnt off them. Boracic acid causes great pain, and should never be employed, and Carron oil does well; but what is wanted is something thick enough to exclude air, alkaline in reaction, and oily. It must not be spread on lint unless put on very thickly and backed up by oilcloth or jaconet. As lard becomes rancid and intensely acid, it should never be used for ointments; vaseline is cheaper, keeps for ever, and is always bland. I gave all these cases an anodyne the moment they entered the ward, and thus saved them much of the shock generally seen. When these large destructions of dermis occur near a joint it is important to resort to skin grafting on a large scale to avoid cicatricial contraction. Many joints were kept efficient by keeping a weight on until the grafted skin had replaced the destroyed

tissue. I removed strips of skin 4 in. long from the outside of the thighs under an anaesthetic, and stitched them across the centre of the large areas under great aseptic precautions, and on removing the dressing a week later was gratified to see that they were firmly adherent. From each of these strips the skinning over process proceeded rapidly, and in another week the weight was taken off, and there was no tendency to retract. I saw some cases where a good man was lost to the service by retraction of his legs, from burns behind the knees, without weights or skin grafting being used. But they did not occur at Lady Wemyss Hospital.

Heart Surgery.

The most striking experience of my stay in France was while visiting the Hôpital du Panthéon, where I witnessed the removal of a bullet from the pericardium behind the heart by Dr. d'Ardennois. In fifteen minutes the skin and muscle over the heart had been incised and lifted up; the ribs nipped through and lifted up on their joint with the sternum; the heart lifted out of the pericardium, all the time throbbing so strongly as to knock the operator's hand away when he tried to catch it; the bullet found, caught, and wriggled out of its bed; the heart put back, ribs sewed together, muscles readjusted, and skin closed carefully. A lady doctor, herself a doctor's wife, assisted, and the accuracy of the x-ray picture in front and profile showed where the bullet was to a nicety.

As a rule we received our cases the same day that they were wounded. But this was not always the case; sometimes, for various reasons, we did not receive them for a week. Many of these were deep, clean cuts, gaping widely, granulating, and bathed with pus. In these cases it was our invariable rule to thoroughly cleanse them with hydrogen peroxide, which cleanses without harming the granulations, and then to pass a silkworm-gut stitch far back from the edge of the wound and a quarter of an inch under it, and so to embrace the whole raw surface in a series of deep loops. When these were tied, the granulating surfaces were brought firmly together. No bad results followed. There was a little suppuration without temperature, because we drained with a few strands of silkworm-gut at the bottom. The country was saved at least two weeks' loss of each man so treated, for in a few days, or a week at most, the wound was healed, instead of taking a month to fill in with granulations.

FAECAL AND INTESTINAL VOMITING AND JEJUNOSTOMY.

By VICTOR BONNEY, M.S., M.D., B.Sc.LOND.,
F.R.C.S., M.R.C.P.,

ASSISTANT Gynaecological Surgeon to the MIDDLESEX HOSPITAL,
AND SURGEON IN CHARGE OF ITS MILITARY BRANCH AT
CLACTON-ON-SEA; SURGEON TO THE CHELSEA
HOSPITAL FOR WOMEN, ETC.

The obstruction was released, but the vomiting never stopped, and the patient died twenty-four hours later.—
Case Report, any Hospital.

The abdominal distension continued to increase, the patient vomited large quantities of brownish fluid, and the pulse became uncountable.—*Another Case Report, any Hospital.*

In November, 1910, a paper of mine appeared in the *Archives of the Middlesex Hospital* (vol. xxi), entitled "Post-operative paralytic obstruction of the intestine, with special reference to its treatment by jejunostomy." Therein I pointed out that the fatal result in these cases was due to toxic absorption from the upper intestinal tract brought about by an acute ascending infection by *B. coli communis* and other organisms of the lower intestine in a state of exalted virulence and activity.

I further pointed out that in these cases the bowel may be divided into three segments, each of which is in a different condition: (1) A collapsed portion, (2) a portion above it much distended with gas, but containing no fluid matter, and (3) a portion above that distended with gas and fluid matter, the fluid being more or less faeculent in character and identical with that vomited.

I showed that in these cases it was proper to open the upper fluid-containing segment in order to drain the

reservoir of toxicity, and useless to open the middle gas-containing segment.

During the time that has since elapsed my confidence in the correctness of the views then expressed has been strengthened, and I hold strongly that in all cases of paralytic intestinal obstruction (whether primary, or secondary to an organic obstruction or to peritonitis), when advanced to the stage of faecal, or short of faecal, intestinal vomiting, should be treated by jejunostomy.

The Character of the Vomit as Indicating the Condition of the Upper Intestinal Tract.

The character of the vomited matter indicates the condition of the upper part of the intestinal tract, for where the vomit is faecal or intestinal the stomach forms the highest part of the fluid-containing segment. This upper segment does not necessarily reach as high in every case of intestinal obstruction when it first comes under clinical observation, nor need it at first include any part of the small intestine; for if the primary obstruction is situated low down in the large intestine, the total area of distension may not at first extend above the ileo-caecal valve. In such the "segment of toxicity" will comprise the caecum and descending colon. In this phase, however, the vomit is neither faecal nor intestinal, but simply the stomach contents.

In all cases of obstruction, however, the stomach and jejunum will eventually be included in the fluid-containing segment, and so soon as this occurs the fact is made patent by the change in the character of the vomit, which at first becomes intestinal and finally faecal.

This upward extension of the limits of the fluid-containing segment is due to a rapid upwardly extending infection of the canal by organisms of the lower intestine.

The effect of an infection by faecal bacteria on the contents of the small intestine is well illustrated by the following case:

A soldier was sent to the military branch of the Middlesex Hospital at Clacton-on-Sea. He had been kicked by a horse and intestine had been ruptured. Immediate laparotomy was performed, and the bowel anastomosed by means of a Murphy's button. When the man went to Clacton, four weeks afterwards, the button was still *in situ*, and could be well seen with the x rays. The abdominal wound presented a fistula from which typical faecal matter, characteristic in odour and non-irritating to the skin, exuded. Two weeks later, the button not having passed and the man being very ill with signs of intraperitoneal suppuration, I operated.

I found to my surprise that the faecal fistula led down to a coil of small intestine some 3 ft. above the point where the button was lodged, which itself was some 3 ft. or more from the ileo-caecal junction. The button was half in and half outside the bowel, the wall of which at the point was in a state of necrosis, and surrounded by a large pelvic abscess. I excised two portions of the gut and performed a double anastomosis, and the man made a fortunate recovery.

The interest of the case from the point of view of this paper is that the presence of the necrotic area in the vicinity of the button had induced an ascending infection, which extended at least 3 ft. above it, and which converted the odourless ichorous contents of the ileum into a stercoraceous, non-ichorous material, identical with that normally found in the large intestine.

This conversion by bacterial agency of the normal contents of the small intestine into a highly toxic fluid is the essential factor in the production of the symptoms of acute intestinal obstruction. The presence of the toxic substances in the bowel excites the mucosa to exude a copious watery secretion which, mingling with the infected fluid already there, itself undergoes corruption. Thus the upper intestinal tract becomes converted into a great toxic reservoir.

The death of the patient is due to the absorption of this toxic material, and the vomiting is Nature's desperate attempt to rid the organism of the poison.

It is here that surgery should step in and drain the reservoir.

The drainage opening must tap the fluid-containing segment. It is useless to open the segment that lies below it; nothing escapes, and I have on several occasions seen a patient die with great distension and vomiting faecal matter to the last, whilst through a free opening into the caecum or ileum not a drop of fluid, not even a puff of gas came!

On the Place of Caecostomy.

Caecostomy is a most effective operation in those cases in which the caecum and ascending colon form the fluid-containing segment; but it is not indicated when the vomit is faecal or copiously intestinal—that is, when the "segment of toxicity" includes the upper intestinal tract.

Jejunostomy.

By making an opening into the jejunum in a case of faecal or intestinal vomiting the source of the vomit is directly tapped and free drainage of the toxic material is established.

No patient should be allowed to die with faecal vomiting if it is possible to perform this operation. Its effect in my cases has been remarkable; in all of them there has been immediate cessation of the vomiting, and all the patients have recovered.

It is true that after jejunostomy a second operation to close the opening has to be faced, but this is not such a serious undertaking as might at first be thought.

Mr. Sampson Handley, in his paper recently published in this JOURNAL,¹ refers to my original paper on the subject, but doubts whether jejunostomy would be successful in cases of post-operative intestinal paralysis. The cases I am now able to report show that it is most successful. Its object is *drainage*, to which all else for the moment must be subservient. There is no fear that jejunostomy will starve the patient of water. Once the vomiting is stopped, the stomach alone is quite capable of absorbing all the water required, and more can be given by the rectum or under the skin.

Mr. Handley suggests instead short-circuiting the jejunum to the transverse colon and then performing caecostomy. Inasmuch as he opens the jejunum, he does actually perform a jejunostomy, the difference from my procedure being that the jejunum drains through a segment of the colon instead of directly through the abdominal wall.

Which of these two channels of drainage will prove to be the best, experience alone can show. Certainly jejunostomy is the shorter and easier operation, and, in view of the septic condition of the bowel, I opine the safer.

TECHNIQUE OF THE OPERATIONS.

The First Operation.

The abdominal incision should be separate from that made to relieve the obstruction. The latter will usually be in the mid-line below the umbilicus. It may have been primarily made there on account of the obstruction or have been made through the scar of the recent operation that preceded the obstructive symptoms. By making a separate incision for the jejunostomy the healing by first intention of the far larger wound below it will not be jeopardized. An opening about 2 in. long, directly above the umbilicus, having been made, the *highest obtainable coil of jejunum* is pulled up. In most cases the coil immediately below the duodeno-jejunal junction may be deliberately selected; but if there be great distension this may be impossible; and the surgeon must then take at random one of the coils lying in the left hypochondrium. The intestine is fixed in the wound by two stout sutures passed through the skin, then through the thickness of the bowel wall, and then out through the skin again at either end of the wound. The intestine is now opened by a small longitudinal incision, the edges of which on either side are sutured to the skin edges of the abdominal wound with a few stout sutures.

On opening the bowel a quantity of gas escapes, and there may be at once a gush of faeculent fluid, but sometimes the latter does not begin to pour out till a little time has elapsed.

Though the fluid must be highly infective, it does not seem to affect the wound to a marked degree, neither does it interfere with the healing of the second wound if such be present.

It might also be supposed, in view of the loose suturing of the intestine to the edges of the wound, that there would be considerable danger of infection spreading to the peritoneum, but in not one of my cases has this occurred.

Subsequent Progress.

During the next twenty-four hours a copious discharge takes place identical with the fluid the patient was vomiting before the operation. After this, as the intestine clears itself, the discharge becomes thinner and odourless, and increasingly bile-stained until it consists of the normal jejunal contents. At the end of a week, or sooner, undigested food particles appear, and the skin in the vicinity of the opening becomes very red and excoriated. The patient rapidly wastes, and it is now time to consider the closure of the opening.

During this period the treatment should be as follows: For the first forty-eight hours nothing but water should be given by the mouth, to which brandy or whisky may be added as required. The amount of water given should not be stinted. After this the patient should be given easily absorbable meat essences and extracts, freely and at short intervals. It is no use giving food substances which require jejunal digestion, like milk, for instance, which is merely passed in clots out of the jejunal opening. Rectal saline infusions with glucose added should also be given every four or six hours. If the patient's condition is very bad continuous infusion of saline solution into the thighs is the best of all restoratives. Brandy may be added in the proportion of 1 oz. to a quart. For the discharge frequent changing of the dressings is required, and the skin should be protected by smearing it with a thick mixture of castor oil and oxide of zinc.

The Second Operation.

At the end of a week or ten days closure of the jejunal opening has to be undertaken. As by this time the skin is very red and excoriated around the opening, the preparation of the operation area should be limited to the application of iodine solution on the table. It is no use attempting a paring operation, the whole opening must be removed, the bowel sutured end to end, and the abdominal wound separately closed. The skin incision should begin $1\frac{1}{2}$ in. above the opening, and continue downwards until the opening is nearly reached. It should then bifurcate to surround the opening $\frac{1}{2}$ in. outside the muco-cutaneous junction and unite again below it. The peritoneal cavity should now be opened above the adherent bowel, and a finger inserted to make out the limit of its deep attachment. Guided by this finger the bowel is entirely freed, bringing away with it that part of the abdominal wall included in the oval area demarcated by the skin incision. The freed coil having been brought up, a clamp is applied to the intestine on each side of the opening, and about two inches from it, so as prevent the escape of the contents. Sterile towels are now packed round the coil so as to exclude the wound edges and the peritoneum and the previously attached portion is cut away down to the mesenteric attachment. An end-to-end anastomosis is then performed with three layers of sutures for extra security. The bowel is dropped back and the wound in the parietes closed with a single layer of stout sutures.

For the first forty-eight hours after the closure it is better to restrict the patients to water by the mouth, but this may be given freely. Afterwards, and up to the end of the first week, the diet should be limited to easily-absorbable meat extracts and essences.

Report of Cases.

I give below short details of six cases of jejunostomy, five of my own (all I have performed) and one of my colleague's, Mr. Bryden Glendining, which he has very kindly given me leave to publish.

CASE I.

Paralytic obstruction of the last 3 ft. of the ileum and of the caecum and ascending colon forty-eight hours after radical removal of carcinoma of the cervix. Faecal vomiting. Jejunostomy was performed with immediate relief. Jejunal opening closed about a week later. Recovery.

CASE II.

A case in which an ovarian dermoid was forced through the wall of the rectum above the floor of Douglas's pouch by the child's head during labour. Primary operation thirty-six hours later; general peritonitis. It being impossible to suture the bowel, the uterus and broad ligaments were sutured to the back of the pelvis, so as to exclude that cavity. Enormous distension and faecal vomiting. Jejunostomy performed two days later

with immediate relief. Jejunal opening closed about a week later. Recovery.

CASE III.

General peritonitis due to a suppurating ovarian cyst. Cyst removed. Obstructive symptoms appeared with faecal vomiting. Jejunostomy with immediate relief. Jejunal opening closed some days later. Recovery.

CASE IV.

Operation for extrauterine gestation. Patient became distended. Mr. Handley in my absence reopened the wound. Patient greatly relieved for two days. Symptoms of acute obstruction then became manifest, with copious intestinal vomiting. I reopened the wound, and found enormous distension of the upper part of the small intestine. Jejunostomy with immediate relief. Jejunal opening closed a week later. Recovery.

CASE V.

Patient had been operated on for papilliferous ovarian cyst two years before. Admitted for intestinal obstruction and faecal vomiting. Scar reopened; many adhesions and great distension found. Jejunostomy with immediate relief. Jejunal opening closed a week later. Recovery.

CASE VI (Mr. Glendining).

Operation for suppurative disease of the uterine appendages. Seventeen days later wound reopened for further collections of pus in the pelvis. Abdominal distension increased, with faecal vomiting and signs of obstruction. Five days later jejunostomy. Stomach washed out and 1 pint of liquid paraffin poured into the bowel. Six days later excision of piece of jejunum and anastomosis. Recovery.

A CASE OF MARKED TEMPORARY APHASIA AFTER LIGATURE OF THE COMMON CAROTID ARTERY FOR TRAUMATIC ANEURYSM.

By FRANK COLE MADDEN, M.D., M.E.L.B., F.R.C.S. (ENG.),

PROFESSOR OF SURGERY, EGYPTIAN GOVERNMENT SCHOOL
OF MEDICINE; SENIOR SURGEON, KASR-EL-AINY
HOSPITAL, CAIRO.

DURING the year 1915 we treated upwards of 5,000 sick and wounded soldiers—British, Australian, and Turkish—in Kasr-el-Ainy; but with all the chances of damage in many cases of bullet wounds we had only one case of obvious penetration of the large vessels of the neck.

This case, which unfortunately ended fatally, reached us many days after the infliction of the wound, and was that of a British soldier with a bullet which had passed through the upper jaw on the right side, then through the soft palate and side of the pharynx and on down the neck in front of the sterno-mastoid. An x-ray photograph showed the bullet lying in front of the body of the sixth cervical vertebra rather to the right side. A well-marked pulsating swelling was present over the carotid artery, on which we proposed operating when the general condition had improved. Our hands were forced, however, owing to the occurrence of repeated disquieting secondary hæmorrhages from the wound in the pharynx. On the advice and with the kind assistance of the late Colonel Stonham, consulting surgeon to the forces, I cut down in the neck and found a very extensive slitting of the internal jugular vein, pouring blood into a very thin-walled pouch, only very imperfectly delimited from the surrounding tissues. There was no injury to the arteries of the neck. Though we were able to secure the divided ends of the vein, the shock and hæmorrhage at the operation were too great to be borne by an already very enfeebled patient, and he died shortly after the operation.

It remained for our civil patients, who were once again admitted to the hospital after the stress of wounded had passed, to furnish us with a much more perfect case of combined injury to artery and vein in the neck, which, for several reasons, is worth placing on record.

History and Condition on Admission.

He was a young Egyptian carpenter, aged 23, named Mustapha Aly, admitted on February 15th, 1916. He stated that he had been stabbed in the left side of the neck with a chisel three days before. At the time there had been considerable hæmorrhage, which had soon stopped. Very shortly after the blow he noticed a swelling at the site of the wound, which induced him to apply for advice. The external wound was situated over the middle of the left sterno-mastoid, and had almost quite healed, but a large pulsating swelling occupied the space

in front of the muscle, and extended well down the neck and towards the outer margin of the muscle. This had all the characters of an arterio-venous injury, and tended to increase slowly in size in all directions during the few days preceding operation. It appeared to be directly in connexion with the left common carotid artery, pressure on which completely stopped the expansile pulsation of the swelling and considerably reduced its size. Beyond the presence of the swelling and slight interference with the movements of the neck, the patient was not in any way bothered.

Operation.

At the operation, on February 26th, a free incision was made from the upper limits of the swelling along the anterior border of the sterno-mastoid nearly down to the sterno-clavicular articulation. After reflecting the skin, dissection disclosed that the main mass of the pulsating tumour occupied the substance of the left sterno-mastoid muscle, and was exceedingly thin-walled in its upper and outer part. By retracting the muscle backwards it was found that the common carotid formed a kind of neck to the sac, and the internal jugular vein passed straight into it. While attempting to clear the neck of the sac from below it gave way and some haemorrhage occurred, which was immediately controlled by pressure on the artery lower down. The common carotid and the internal jugular vein were then ligatured well below the lower limits of the sac, and the difficult part of the operation appeared to be over. Then the sac burst, and we saw that there was a considerable length of the internal jugular vein split inside it. Haemorrhage was free, and only partially stopped by pressure; and it was not till, after considerable tedious dissection, we had ligatured the internal jugular vein and a large posterior tributary and the external carotid artery above that all bleeding ceased. The sac was then opened up and cleared, and it was seen to be confined to the body of the muscle. Beyond the limits of the muscle there was no definite sac, and it is remarkable that a more extensive and diffuse extravasation of blood had not taken place. The operation took nearly two hours, and the patient, who had been given intravenous saline injection on the table, had a fairly good pulse, and under appropriate treatment soon rallied.

After-History.

But he lay in a dull, heavy, stupid condition for twenty-four hours. After that he gradually seemed to understand what was said to him, but was quite unable to put any of his thoughts into words for several days. His pupils were equal, as were his radial pulses; he swallowed well and, though quite aphasic, was able to make certain grunting noises, which reassured us as to the integrity of his recurrent laryngeal nerve. For two or three days there was a definite paresis of the right side, and the grip of the right hand was appreciably weaker than the left. Rectal and bladder functions were not interfered with in any way after the first twenty-four hours.

The peripheral symptoms very soon passed off, and in ten days' time no difference in the power of the limbs could be distinguished. The mental dullness rapidly improved, but recovery from the aphasia was a much more gradual process. About fourteen days after operation, much to his delight and to our satisfaction, he greeted me by articulating quite distinctly, after one or two false starts, "My name is Mustapha" (in Arabic), and two days later he wished me "Good-morning," without any preliminary bungling. Very gradually his re-education has proceeded, until now, four weeks after operation, he is sufficiently recovered to be able to tell us where he lives and to ask to be discharged.

His wound healed perfectly, and there is only a small hard lump in the muscle. In the left side of the neck no dilatation of veins can be seen, and there is no pulsation to be felt either along the course of the carotid or over the facial or temporal arteries. The radial pulses are the same on both sides.

Every day his aphasia is less, and it is very interesting to note his distress and annoyance at not being able to put his ideas into words, especially now that his mental condition is so thoroughly re-established and his ideas flow so much more readily. So rapid has been his progress in the last few days that I am hopeful he will eventually completely recover without any physical or mental defect.

NOTES ON A FATAL CASE OF ACUTE NEPHRITIS OCCURRING IN THE EXPEDITIONARY FORCE.

By RICHARD C. CLARKE, CAPT. R.A.M.C.(T.F.),
ASSISTANT PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

My reason for publishing these notes on this single and rather incomplete case of nephritis is that I think it of peculiar interest; it gives me at any rate food for thought, and may help to elucidate the problems of this disease. Also, although I am, I admit, out of touch with the literature, I understand that very few complete *post-mortem* examinations on early cases of nephritis occurring in our forces in the field have been made.

Driver L., A.S.C., attached to a field ambulance, was admitted into the clearing station on February 17th, 1916. On January 30th his urine was examined, in course of a routine

examination of his unit by Captain McLeod of a mobile laboratory, and found to be normal. On February 7th he reported sick, and two days after he was admitted into the field ambulance with follicular tonsillitis. The temperature never exceeded 101° F. In two days the fever subsided and the throat cleared up. At this stage a moderate amount of albuminuria was present, but no oedema. For the next three days the temperature kept down, and the only thing which prevented his being returned to duty was the presence of complete anorexia and some vomiting.

On the fifth day in hospital his face was noticed to be puffy, and there was a large amount of albumin in the urine. The next evening the temperature ran up to 102.6° F., and in the morning he was evacuated to the casualty clearing station. He arrived with the convoy at about 2 p.m., and I examined him at 3 p.m. He looked very pale and ill and complained of headache and weakness. There was no marked oedema of the face, though there was some swelling of the ankles and a well-marked lumbar pad. The temperature was 100.5° F., and the tongue furred, brown, and extremely dry. The pulse was 100 and of fair quality. Except that the heart sounds were rapid and slightly feeble and that there were rhonchi at the bases, the examination of the chest was negative. The abdomen was somewhat tumid, and there were signs of moderate ascites. The liver dullness was higher than normal behind, and the edge was felt in front below the costal margin. The spleen was not felt. Examination of the central nervous system elicited nothing unusual. The fundus was not examined. His general condition, though serious, did not lead me to suppose then that he would die. The urine was fairly profuse, pale, and clear. On boiling it was solid with albumin. On spinning the sediment showed hyaline casts, often with polymorphonuclears attached and free polymorphs. There were no epithelial casts, and nothing suggestive of the presence of epithelial cells.

I saw him again in the evening and found him no worse. Towards the morning he had diarrhoea and abdominal pain, and at 8.30 a.m. suddenly collapsed. I saw him shortly after, and found him cold and pulseless, but quite conscious and complaining of abdominal pain. He died an hour later, perfectly conscious to the last; in fact, he dictated a letter home some ten minutes before he died.

Necropsy.

I performed a *post-mortem* examination two hours after death, with Captain McLeod and Dr. Amecielle of the French medical service.

There was no abnormal pericardial fluid. The heart was small and the walls of the left ventricle distinctly thickened. The valves and aorta were normal. There was oedema of the bases of the lungs. The peritoneal cavity contained about 2 pints of opalescent fluid. The intestines were normal.

The liver was somewhat enlarged and fatty. The spleen was enlarged slightly, flabby; no necrotic patches. The kidneys were large, firm, and congested. There was much swelling of the cortex and pyramids, the latter standing out very clearly. The capsule stripped easily. The bladder was normal, as was the pancreas. The suprarenals showed some medullary hypertrophy and medullary haemorrhages. The meninges were slightly injected and the brain a little oedematous.

Blood taken from the vena cava contained 1.80 grams of urea per litre. A blood film taken just before death showed a high polymorphonuclear leucocytosis, estimated at about 40,000.

Bacteriological Data.—The peritoneal fluid yielded on spinning a sediment of leucocytes, mostly polymorphonuclear, amongst which were very numerous streptococcal chains of medium length. No organisms were found in smear preparations of the kidney or spleen pulp, but polymorphonuclear leucocytes were very numerous in the smears from the spleen. A growth of streptococci was obtained both from the kidney and the spleen. The organism had moderate haemolytic power; 5 c.cm. of a thirty-six-hour culture in horse serum bouillon, when injected subcutaneously into a rabbit, did not cause the death of the animal. A control injection into a similar rabbit of a streptococcus taken originally from a wounded French soldier in subculture for five or six months killed the animal. The only other organism isolated from the viscera was a coliform bacillus, which, as it grew from only one of several preparations of the kidney, can, I think, be disregarded as a *post-mortem* examination.

Microscopic sections of the organs showed that in the kidney the main brunt of the attack had fallen on the interstitial tissue. The glomeruli had escaped entirely and most of the tubules. In the interstitial tissue were several areas of acute congestion. In these were foci of polymorphonuclear and large mononuclear renocytes, forming microscopical abscesses. The tubules running through these areas showed some degeneration, but no desquamation of the cells. Moreover diapedesis of polymorphonuclear cells was seen taking place through the basement membrane, and some were seen in the lumen of the tubules. Globules of fat were seen in many of the liver cells. There were a few areas of cellular necrosis in the cortex of the suprarenal. The medulla showed haemorrhages and collections of polymorphonuclear leucocytes, and there was distinct medullary hyperplasia. Lungs showed some foci of congestion and oedema. The spleen was congested with an undue amount of leucocytes. The heart and pancreas were normal.

The actual cause of death in this case was, I think, septicæmia in a patient whose resistance was lowered by a certain amount of uræmia. The slight uræmic symptoms, namely, headache and anorexia, the mode of death

and terminal peritonitis all point to this. The case, however, presents many problems of interest. It started with tonsillitis probably of streptococcal origin, and at that time there was no albuminuria. The question arises, then, Did the tonsillitis pass on to a septicaemia, and cause a streptococcal interstitial nephritis, or did the toxin circulating in the blood from the focus in the throat cause the kidney trouble, leading to a general lowering of resistance, which allowed the streptococcus to get a footing in the general circulation? In other words, was this nephritis of pyaemic or toxic origin?

Personally I am inclined to the former view. I admit that no organism was demonstrable in the sections, and the fact of its growing from the kidney pulp can be explained by a general blood infection. I support my case entirely on the microscopical abscesses in the interstitial tissue of the kidney, and on the clinical course of the case.

My thanks are due to Captain McLeod, R.A.M.C., who did the bacteriological work, and to Dr. Amecielle, of the French medical service, who got the tissues sectioned for me, and gave me his valuable opinion on them.

INJURY TO THE INTERNAL EAR PRESENTING SOME UNUSUAL FEATURES.

BY

CAPTAIN H. LAWSON WHALE, M.D., F.R.C.S.,

R.A.M.C.(T.),

THE BELGIAN FIELD HOSPITAL.

SOLDAT D. was admitted on December 29th, 1915, with a bullet wound of the head.

Entrance wound left frontal eminence. No exit wound. Skiagrams (1) on admission, showed no bullet, but only splintered bone below the wound; (2) on February 2nd, showed no bullet, but a rarefied area, where at operation the bone spicules had been removed.

Treatment.—On admission the patient was anaesthetized and trephined. Fragments of bone were removed from the frontal lobe of the brain and the wound dressed with gauze. There was nothing to suggest a fractured base. There were no signs of focal injury nor of intracranial pressure. As regards his head wound, the patient made an uninterrupted recovery.

Evidence of cerebral irritation (sulkiness, mischievousness, resentment of any one approaching him) persisted for some days, and disappeared with the sudden onset, on January 8th, of escape from the left ear of fluid, which flowed slowly but steadily, was quite clear, and reduced Fehling's solution. With the flow of cerebro-spinal fluid all signs of cerebral irritation ceased. The flow persisted until January 24th.

Otology.—The right ear was normal. In the left ear, half an inch from the external meatus, a sessile swelling of the bony roof bulged downwards, occluding three-quarters of the meatal lumen and preventing inspection of the membrane. It was covered with intact skin, sensitive and stony hard to the probe, and resembled a mental exostosis. It was impossible to be certain that it was the result of the injury. This appearance persisted unchanged as long as the patient was in hospital, so that the membrana tympani was never seen.

Hearing was at first good, and equal on both sides to watch, speech, and whisper; no tuning-fork was then available. The hearing on the right remained normal, while on the left it became progressively worse. On January 26th he heard speech left 18', whisper 4'; on February 6th, speech 2', whisper 3'. On February 24th I obtained a tuning fork (D.V. 512); Weber to right; absolute bone conduction on left—15 secs. On and after March 5th, for speech, watch, and tuning-fork, both air and bone conduction were nil on the left side.

Equilibrium.—As soon as the patient was well enough to be lifted into a sitting position he fell over on to his left side. In a few days he could sit up without support, and walk unsteadily by January 15th. After January 26th he could walk straight with his eyes open; but with eyes shut staggered to the left. He next developed a crab-like gait (with eyes shut), diverging constantly to the left, and crossing the right foot over the left as he walked, to avoid falling to the left. On and after March 5th his gait was normal, with eyes opened or closed.

Evidence as to Cerebellar or Vestibular Lesion.—There was never any asthenia, dysidiadokokinesis, giddiness, vomiting, or nausea. There was no indication for lumbar puncture or examination of optic discs.

Nystagmus.—No galvanic apparatus or rotation-chair was available. Repeated observations were made, with the head in various positions and water at different temperatures; and the ears were irrigated both separately and simultaneously. The mean results obtained were as follows:

Spontaneous Nystagmus.—On deviation to right: Fine, pure horizontal, never of more than first degree. This became progressively less marked, and no nystagmus was obtainable after February 17th. On deviation to left: No nystagmus.

Caloric Response.—Head backwards 60 degrees; water at 90° F. ran in for two minutes. Right: During the persistence of spontaneous nystagmus on deviation this was always made

coarser and raised to third degree. After spontaneous nystagmus had ceased (February 17th), irrigation elicited a similar but less violent normal response. Left: On deviation to this side there was never any response to irrigation. But, for as long as the spontaneous nystagmus to the right persisted, this could always be inhibited for periods varying from two to fifteen minutes by warm irrigation of the left ear.

To test this inhibitory effect of stimulating the left labyrinth on nystagmus to the right, the two ears were simultaneously irrigated several times after February 17th, when spontaneous nystagmus to the right had ceased. But at no time did the irrigation of the left ear have any effect on the nature or duration of the nystagmus obtained by simultaneous irrigation of the right ear.

On his discharge to the base, after ten weeks in hospital, he had on the right side normal caloric labyrinthine response and normal hearing. On the left side, total loss of labyrinthine response and complete deafness. Gait and general health normal.

The signs of cerebral irritation during the early days disappeared suddenly and permanently with the appearance of cerebro-spinal otorrhoea, which again ended spontaneously sixteen days later. Although there had been no classical signs of compression, it seems reasonable to suppose that the irritative stage might have merged into such, and that the cerebro-spinal flow was nature's decompression. The gradual loss of spontaneous nystagmus to the sound side and of a tendency to fall to the injured side, were merely evidence of recovery from partial or complete unilateral loss of labyrinthine function. Since stimulation of the left labyrinth always inhibited any spontaneous nystagmus to the right, but later on failed to inhibit caloric nystagmus to the right, and since also there was a progressive loss of hearing, there was obviously a progressive lesion of cochlear and vestibular apparatus.

The results of caloric tests on the left ear seem puzzling. Whether the lesion was in any part of the left external semicircular canal or in the nervous mechanism proximal to this, it was striking that stimulation should inhibit nystagmus to the right, but never succeed in eliciting nystagmus to the left.

The bullet was never removed from the skull, nor seen in a skiagram. It may never have entered, although the shape of the wound suggested penetration rather than glancing. If it is still in the patient's head, that would not seem to account for the findings here reported.

THE TREATMENT OF DIABETES.

BY

JOHN HUME, M.D., D.P.H.,

PERTH.

The cause of diabetes is looked upon as the result of the faulty action of certain glands, whose action appears to result from, or be aggravated by, absorption of toxic products produced in the alimentary tract.

This statement appears to be borne out by the remarkable improvement which takes place in diabetics when the treatment is directed to controlling toxic production in the bowel. The beneficial effects of removing alimentary toxæmia is fully explained in an article on starvation and purgation by Dr. Guelpa of Paris.¹

There is a variation each day in the amount of sugar in the urine of diabetics which takes place independently of treatment. In my opinion this is due to the condition of the bowel, as I have invariably found the sugar content of the urine high when the bowel was loaded; after it was cleared by aperients a reduction in the amount of sugar was apparent.

As the treatment of diabetes by means of a starch-free diet is very irksome to the patient, and often unsatisfactory, I have for several years treated my diabetic patients by fasting, and cleansing of the alimentary tract, at the same time allowing a diet from which starch was not entirely excluded.

As early as three days after commencing treatment, I have invariably found alleviation of the symptoms, the thirst much less, the craving for food not nearly so pronounced, the pruritus, if present, markedly relieved, and the patient all round much better than on a rigid starch-free diet and opium derivatives.

Mode of Treatment.

I thoroughly inspect the mouth, have any defective teeth removed, and enjoin the necessity of thoroughly cleansing the teeth and washing out the mouth frequently.

The fast I begin with is generally about fourteen hours' duration. The best time to commence is in the evening. I allow a light meal about 5 p.m. Two hours after I give a dose of castor oil. The patient can rinse out the mouth with warm water, if desired, two or three times during the fast, but on no consideration must anything be swallowed, not even water, as I find the results are not so satisfactory when water is allowed. At 9 next morning I give a second dose of castor oil and then no food for two hours. By 11 a.m. the bowels have, as a rule, acted, and I allow the patient to have breakfast. There is therefore a period of absolute fasting between the two medicines. In succeeding fasts salines can be used, the object being to secure a thorough evacuation and to reduce the intestinal flora as far as possible. The patient can easily go through the same routine every second night, and after he has become accustomed to the treatment the duration of the fasts should be prolonged by beginning earlier in the afternoon and extending them next day. At the end of a fortnight a fast of twenty-four hours can easily be done two or three times a week.

It is better in the earlier fasts to keep the patients in bed, as I find they are more easily managed and it is pleasanter for themselves as they can more readily keep warm and do not have the same temptation to stop the fast as they would have if they were going about. In many cases the disappearance of the sugar is complete. I generally recommend, however, that there should be one fast of eighteen hours each week carried out in the same way.

If a small quantity of sugar persists I recommend two fasts each week of about fourteen hours, and find this quite sufficient to prevent the other symptoms of the disease from manifesting themselves and to allow the patient to attend to his duties.

The following four cases, selected at random from my notes, are typical of the results to be obtained:

1. Mrs. H., aged 56, thirst very marked, intense pruritus, specific gravity urine 1024, sugar 8 per cent. Had been under treatment previously to becoming my patient; at end of first week after commencing treatment the thirst was almost nil, there was great improvement in the pruritus, and the sugar was only 5 per cent. At end of first month 1 per cent. and no sugar present at end of six weeks.

This patient has an occasional fast and has been working regularly for three years now.

2. D. McF., aged 49, urine specific gravity 1026, sugar 9 per cent., thirst marked, and a considerable degree of mental disturbance. He had previously been under treatment for four months. In six weeks after commencing treatment he returned to his work. Fourteen months ago he went to America and occupies a good position. He does a fast of about eighteen hours once in ten days.

3. Mrs. J., aged 62. When I first saw her the fourth toe on the left foot was gangrenous. The specific gravity of the urine was 1035 and the sugar 11 per cent. Very great thirst and pruritus were present. The toe was removed and wound healed satisfactorily. At end of four weeks after commencing treatment only 2 per cent. of sugar remained, and at end of six weeks none was present. She does a fast of eighteen hours about every six days.

4. J. D. (male), aged 64, specific gravity urine 1028, sugar 8 per cent., and a trace of albumin was present. At end of six weeks no albumin and only a trace of sugar left. The patient felt much better and returned to work. He has kept well and does one fast of fourteen hours in the fortnight.

¹ BRITISH MEDICAL JOURNAL, October 8th, 1910, p. 1050.

THE British Fire Prevention Committee (8, Waterloo Place, S.W.) has issued a memorandum on the use of a mixture of sawdust and sodium bicarbonate for extinguishing small fires occasioned by the ignition of petrol and other inflammable liquids. The sawdust must be free from shavings and chips, but need not contain added moisture. When applied to the surface of the burning liquid it floats for some time, thus excluding the oxygen of the air and smothering the fire. The addition of sodium bicarbonate is advantageous, for the heat liberates a certain amount of carbon dioxide, which adheres to the sawdust, and slightly assists in extinguishing the fire. The proportion should be about 10 lb. of bicarbonate to one bushel (or, say, 12 lb.) of sawdust. The powder must be applied rapidly and systematically by a sweeping motion of a shovel, so as to cover the whole of the burning surface; the method, it is thought, will prove particularly useful in motor garages and hangars.

NEW FORMS OF PLATING DISHES FOR
THE CULTIVATION OF BACTERIA.

By S. DELÉPINE,

DIRECTOR OF THE PUBLIC HEALTH LABORATORY, MANCHESTER.

OWING to the difficulty of obtaining at the present time suitable dishes for making plate cultures I have adopted several devices.

1. The object of the first was to utilize the stock of Petri dishes which I had in the laboratory, which was insufficient when it became necessary to have some eight hundred dishes available daily in connexion with our military work alone.

I had a number of shallow flat metal lids made to fit the tops and bottoms of the existing dishes, so that each Petri dish could be utilized to make two plates, thus doubling the stock available (Fig. 1). I found that these metal lids when well tinned answered their purpose. They, however, require frequent polishing in order to keep the surface smooth and free from rust.

1 One half of a Petri dish with a metal lid to replace the other half. The unevenness of the bottom of the Petri dish is exaggerated.

2 A plating dish made by forcing a glass plate into a flexible metal rim.

2. I have also made plating dishes by inserting round pieces of plate glass in a thin rim of well tinned metal or waterproofed cardboard, etc. (Fig. 2). These plating dishes are very much cheaper than the old-fashioned Petri dishes, and appear to me to be better, because the glass bottom is perfectly flat and of equal thickness, and permits of the media being more evenly spread. They stand sterilization perfectly well, and the bottom is clearly visible up to the edge. I have by numerous experiments ascertained that tin does not appreciably affect the growth of bacteria; aluminium is less suitable, but duralumin could be used instead of tin, if sufficiently thin rims could be made with this alloy.¹

3. A more expensive form of metal rim has also been made for me, which consists of two concentric rings of well-tinned metal (block tin or duralumin would be better); the inner is screwed into the outer, which is provided with a flange, against which the glass bottom plate is fixed when the inner rim is screwed home (Fig. 3). The advantage of this form, which is more expensive, is that the glass plate can be replaced easily when broken.

3 A "plating dish" made by fixing a glass plate by screwing two metal rings together.

4 A "plating dish" made by fixing a rim of metal to a glass plate by means of coagulated albumin or collodion.

4. A much older design (which I used as far back as 1887, in order to obtain even layers of cultivating media, and plates more suitable for photographic purposes than those made in Petri dishes) is even simpler, but somewhat less convenient than the previous forms. It consists of a square or round tin frame; one surface is perfectly flat, and is fixed to a bottom glass plate by means of coagulated blood serum, collodion, or oxidized linseed oil (Fig. 4).

To make a plating dish with such a frame, a perfectly clean glass plate of suitable size and shape is placed over a metal plate heated to the temperature of boiling water. The surface of the frame which is to be fixed to the glass is painted evenly with fresh blood serum or white of egg. The frame is then pressed with the painted surface against the hot glass, and allowed to remain under slight and even pressure for a quarter of an hour or longer on the hot plate. At the end of that time the albumin is quite coagulated and dry, and the frame is so firmly adherent that sterilization by steam can be carried out several times without causing any separation.

All this apparatus can be obtained from Messrs. Chas. H. Hearson and Co.

MEDICAL, SURGICAL, OBSTETRICAL.

MENTAL SYMPTOMS IN ACUTE TETANUS.

CAPTAIN EVERIDGE'S case of tetanus complicated with mental symptoms (BRITISH MEDICAL JOURNAL, March 25th) reminds me of a very similar case I had under my care in 1891. A negro convict at the Penal Settlement in British Guiana was admitted with tetanus of moderate severity. I treated him with chloral hydrate, giving just sufficient to keep him constantly under its influence.

The case, though not severe, was obstinate, and the total amount of chloral administered was considerable. As he was recovering from the tetanus symptoms almost identical with those described by Captain Everidge developed, hallucinations being very marked. There was no rise of temperature, which had not at any time during the attack been much above normal.

I attributed the mental symptoms to the chloral and discontinued it, and the symptoms gradually passed off. Recovery was complete about a week after the chloral was stopped. In Captain Everidge's case the chloral dosage was large, and in view of my own case I think the mental symptoms might be more rightly attributed to this than to the carbolic acid.

W. F. LAW, Lieutenant (temporary),
Military Hospital, Cork. R.A.M.C.

THE INGUINAL INCISION FOR INTRASCROTAL AFFECTIONS.

It is hardly likely that the proposal to utilize an incision in the inguinal region for dealing with all, or most, affections within the scrotum contains anything particularly novel, but the success which has followed my own efforts tempts me to give it publicity. The chief reason for adopting the incision is to obtain a route into the scrotum that avoids the skin of this region. I doubt if there is any part of the body surface so difficult to sterilize or render aseptic. The anatomical construction of the region largely accounts for this. The skin is in a constantly corrugated condition, and for that reason difficult to cleanse by the ordinary processes of bodily ablution. It possesses an unusually large number of very coarse hairs which implies large hair follicles capable of harbouring various kinds of micro-organisms. Among the ordinary run of hospital patients the skin of the scrotum is frequently deeply ingrained with "dirt." Thus, then, it frequently happens that by none of our ordinary antiseptic applications can we gain that amount of sterilization which will ensure an incision through the scrotal skin remaining aseptic. Another rather striking feature about the skin of the scrotum is the readiness with which it sweats when confined under a dressing. The surface layer of epithelium is cast off, and this, with the exudation, produces a particularly offensive odour. Such a condition readily infects any wound made for dealing with intrascrotal conditions. The difficulty encountered in trying to render the skin surgically clean seems to be due to the peculiar susceptibility it has to either carbolic acid or to iodine. I have often seen the application of either of these agents—and I might add also rectified spirit—lead to an amount of irritation that sometimes presented the red, weeping appearance of an acute eczema. Why this should happen it is difficult to say, except it be that the corrugated condition of the skin creates small recesses in which the solutions lodge, and so have a longer period upon which they can act on the tissue. Apart from all consideration is connected with the difficulty of rendering the skin aseptic, there is another disadvantage, and that is the extreme degree of venous vascularity of the scrotum; this might not in itself be difficult to deal with were it not for the laxity of the tissue in which the many venules are coursing. It is not easy to secure these vessels by ligature; and we have no means of exercising the pressure which it is possible to apply in other parts of the body. The result, too frequently, is oozing into the scrotum and distension of the part with blood clot. All these drawbacks are overcome by approaching the scrotal cavity through an incision made in the inguinal region. When the inguinal canal is freely opened up the contents of the scrotum can be withdrawn into the wound and dealt with

as required. We can thus deal with any condition of the testicle, with hydroceles, and with varicoceles. It is not possible to ensure, when, for instance, we have had to remove the testicle or dissect out the sac of a hydrocele, that no oozing of blood will take place into the lax tissues of the scrotum; for this reason, therefore, it is advisable to pass a drainage tube down to the bottom of the scrotal cavity; as an aid to proper drainage, it is of considerable advantage to raise and support the scrotum on a thin wood or cardboard shelf secured between the legs.

While this particular incision is frequently used for excising a portion of the pampiniform plexus in varicocele by withdrawing the cord with the dilated plexus of veins from the scrotum, I have not seen any mention of its employment for dealing with hydroceles and testicular affections of reasonable proportions. It is more specially for these two latter conditions that the inguinal approach to the scrotal receptacle seems worthy of being more widely known.

A. ERNEST MAYLARD, B.S., M.B.Lond.,
F.R.F.P. and S.,
Surgeon to the Victoria Infirmary, Glasgow.

EARLY DIAGNOSIS OF WHOOPING-COUGH.

THE early diagnosis of whooping-cough is one of the trials of the general practitioner, and, in the absence of an epidemic, one is liable to be misled into allowing a child with an apparently harmless cough to infect others while the unmistakable signs which subsequently develop are still lacking.

During an outbreak last year I had considerable opportunity for observing probable cases in the earliest stages, and I found that every case of suspicious cough which showed marked conjunctival congestion in the region of the external canthus subsequently developed whooping-cough. In examining for the sign one directs the patient to look towards the nasal side of the eye under examination, when, on separating the lids at the external canthus, a tumid, congested mass somewhat resembling a large phlyctenule may appear on the bulbar conjunctiva, just within the external canthus. This swelling may or may not be accompanied by injection of the palpebral conjunctiva, but I have come to regard it as an indication in doubtful cases of this nature.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

KING'S COLLEGE HOSPITAL.

A CASE OF HIATAL OESOPHAGISMUS IN A MAN AGED THIRTY-SIX YEARS.

(Under the care of Mr. BOYCE BARROW.)

[Reported by C. P. G. WAKELEY, M.R.C.S., L.R.C.P.,
House-Surgeon; Temporary Surgeon, R.N.]

E. C. B., aged 36, was admitted to King's College Hospital on October 5th, 1915.

History.

He was healthy up to the age of 20, when he had a bad attack of pleurisy with double pneumonia; soon afterwards he began to vomit after food, and had a cough which kept him awake at night, and persisted until he vomited; then he was able to sleep. This occurred two or three times a week. The vomiting became gradually worse, and the patient developed a feeling of choking after meals, sometimes in the middle of a meal; this condition was relieved by brandy, and the food seemed to pass into the stomach. At the age of 23 he went to Bournemouth for a rest cure; afterwards he was advised to go to the Woking Cottage Hospital, where he was treated for gastric ulcer for six weeks. As his condition did not improve, he was sent to Guy's Hospital; here he was fed by nutrient enemata, and only given fluids to drink, but the vomiting persisted. After this he lived at Mero in Wiltshire for two years; he was under constant supervision, and was given bismuth for the gastric condition. In 1912 a surgeon

told him he was suffering from excess of gastric secretion, and advised him to wash out his stomach every day; the sickness was temporarily relieved by this, but gradually returned. In 1914 another surgeon told the patient that he was suffering from intestinal stasis, and advised resection of the colon. This was refused, and in October, 1915, he was admitted to King's College Hospital under Mr. A. Boyce Barrow.

Condition on Admission.

The patient was very thin and weak-looking; he vomited all food, even fluids, and was fed by nutrient enemata for the first two days in hospital. The stomach was washed out twice a day, but even this did not stop the vomiting. A test meal was given on two occasions; both times the patient vomited the whole meal about three-quarters of an hour afterwards. The report from the clinical laboratory was as follows: Volume, 14 cc.

FIG. 1.—Immediately after meal.

FIG. 2.—Thirty minutes after.

acidity = 0.017 per cent. HCl; no physiological HCl present; lactic acid absent. As this report seemed to indicate disease of the stomach, a bismuth meal was given. The figures, which are tracings taken from the x-ray plates and reduced, show the condition of affairs at various times after the meal. Fig. 1, taken immediately after the meal was finished, shows marked dilatation of the oesophagus to the right side; no food had entered the stomach. Fig. 2, taken thirty minutes after the meal, shows food entering the stomach from the oesophagus and a small portion in the pyloric end of the stomach. Fig. 3, taken an hour and three-quarters after the meal, shows food still in the oesophagus, a small amount in the pyloric end of the stomach, and some in the small intestine. Fig. 4, taken three hours after the meal, shows that the oesophagus still contained food, and was dilated; and Fig. 5, taken six hours after the meal, shows the oesophagus in a similar condition. Fig. 6, taken twenty-three hours after the meal, shows traces of

FIG. 3.—One and three quarter hours after meal.

FIG. 4.—Three hours after.

food in the oesophagus and some in the ileum. Fig. 7, taken thirty-one and a half hours after the meal, still shows bismuth residue in the oesophagus, but some of the food had reached the caecum. Shortly after the last x-ray plate was taken the patient vomited 5½ oz. of food consisting mostly of bismuth. The conclusion to be drawn from these series of x-ray photographs was that there was a condition of cardiospasm of the oesophagus. It was impossible to pass a bougie into the stomach, even when passed down an oesophagoscope. An opaque bismuth bougie was passed as far as possible, and the patient examined by the x rays. The bismuth tube was seen to pass along the upper surface of the diaphragm and lie

beneath the heart; it could not be made to enter the stomach. Fig. 8 is a drawing (reduced) from the x-ray plate.

Operation.

Mr. Barrow decided to operate with the idea of trying to dilate the stricture from the stomach, and, failing this, to perform a gastrostomy. On October 13th an incision was made one inch to the left of the middle line, the rectus muscle exposed and split longitudinally, and the posterior layer of the rectus sheath and peritoneum incised; the stomach was found empty, and in a semi-contracted condition. There was no sign of malignant disease or any thickening in the region of the cardiac orifice, the opening was very small, and could be felt by a finger invaginating the anterior wall of the stomach and pushing this upwards to the cardiac orifice. The rest of

FIG. 5.—Six hours after meal.

FIG. 6.—Twenty-three hours later.

the alimentary canal appeared to be normal. The stricture was dilated to a certain extent by the index finger of the operator being pushed well through the cardiac orifice into the lower end of the oesophagus; adhesions were felt to give way. It was decided to perform a gastrostomy in case the stricture closed again. A portion of the anterior wall of the stomach was attached to the abdominal wall after the manner suggested by Frank, but the viscus was not opened. The abdominal incision was closed.

The patient was very comfortable, and did not experience any anaesthetic vomiting. He was fed on liquids for the first two days, then he was given milk puddings, which kept down; from that he was given fish, chicken, and meat, things he had not been able to eat for sixteen years. The patient left hospital on November 5th. He never vomited once after his operation, and during the last two weeks in hospital gained 5 lb. Since leaving hospital his doctor in Dorset writes: "He has gained over a stone in weight since leaving hospital, and eats all kinds of food with a hearty appetite."

The following points require a little consideration:

1. The test meals which were given undoubtedly never reached the stomach, but remained in the dilated lower

FIG. 7.—Thirty-one and a half hours after meal.

FIG. 8.—Position of oesophageal bougie.

end of the oesophagus, and this explains the fact that there was a total absence of hydrochloric acid; this fact, together with the wasted condition of the patient, suggested gastric carcinoma.

2. The dilatation of the oesophagus was towards the right; the cause of this seems to be the fact that the aorta lying towards the left side and being a resisting structure prevents any dilatation towards the left side.

In conclusion, I should like to express my thanks to Mr. A. Boyce Barrow for allowing me to publish this case, and to Dr. R. Knox, honorary radiographer to King's College Hospital, for his kind help in getting the tracings of the bismuth meal.

Reports of Societies.

THE RATIONALE AND PRACTICE OF CHEMOTHERAPY.

At a meeting of the Dermatological Section of the Royal Society of Medicine on April 13th Mr. J. E. R. McDONAGH gave a summary of his researches on syphilis, culminating in the introduction of some new remedies. The investigation of the chemistry of the parasite showed, he said, that it consisted mainly of lipid-globulin molecules, more resistant to reagents than the lipid-globulin molecules of the host's cells. The conditions leading to infection were conceived to be as follows: Should a spore be able to take some of the oxygen required by the cell it hoped to enter, the normal ratio between the oxygen and the carbon dioxide of that cell would cease to exist, the consequence being that the normal hydrogen ion concentration or the oxidase-reducase system would be temporarily deranged, with the result that the local surface tension of the cell would be such that the spore was easily able to enter it. Defence against the parasites was effected locally by the plasma cells, and generally by the serum antibodies, and was due in both cases to lipid-globulin molecules. The death of the parasites was due to the chemico-physical process of adsorption, and was regulated by three factors: (1) Specificity, which depended on the existence of homologous stereochemical molecular configuration on the part of the molecules of the host and of the parasite; this was regulated mainly by the amino-groups; (2) the high degree of permeability of the adsorbed molecules; and (3) the amount of active oxygen, which depended on an oxidase-reducase system associated with serum complement. Treatment assisted the host's resistance by increasing his amount of active oxygen; this could be effected both by metals and non-metals. They became attached to the lipid-globulin molecules, and acted as catalysts; strongly adsorbed metals (arsenic, aluminium, iron, and possibly antimony and mercury) produced extra active oxygen directly; non-metals (iodine and sulphur) acted indirectly by increasing the production of active hydrogen. These and other considerations led to the investigation of various drugs. A sulphur compound—diortho-aminothiobenzene ("intramine")—was found to act extremely well. It was absolutely non-toxic. The usual dose was 1 gram suspended in 9 c.c.m. of olive oil or liquid paraffin and injected intramuscularly. The pain which followed usually rendered the patient *hors de combat* for a week; but however bad the local reaction, no induration was left. In early syphilis salvarsan should be given first and followed by intramine; the arsenical preparation killed the spirochaete and the sulphur compound killed some of the other phases of the *Leucocytozoon syphilidis*, so that symptoms vanished more quickly than after salvarsan alone. In the recurrent and late stages the effect of intramine was most marked, and late syphilitic lesions, which had remained practically uninfluenced by salvarsan, with mercury and iodides subsequently, had been treated with immediate success. Good results were obtained in syphilitic glossitis of twenty-five years' duration and in degenerative myelitis and encephalitis, also in cerebro-spinal meningitis. Iodine, like intramine, adsorbed hydrogen and hydroxyl ions to form peroxide for the oxidase system, hence its action was more marked in late than in early syphilis. Iodine increased the action of intramine, and should be prescribed before the latter, intravenously in the colloidal form. The effect of intramine in late syphilis could be enhanced by following up with injections of metallic compounds. A striking case was cited by way of illustration of a patient suffering from the depressive type of degenerative encephalitis, who was given two intramuscular injections of intramine; most extraordinary improvement followed. A third injection made the case worse, according to the expectation of Mr. McDonagh, who hazarded the opinion that if a metallic compound were now to be given the improvement would be sudden and greater than on the first occasion. An intravenous injection of galyl was administered, with the result that in forty-eight hours the patient had become a rational individual. Interstitial keratitis, a lesion uninfluenced

by salvarsan, cleared up at once with intramine in a most marvellous way. Intramine might also be employed in the treatment of lupus, chronic gonorrhoea, and chronic ulcers. Ehrlich was led to experiment with arsenical preparations because the disease which he hoped to combat was sleeping sickness and arsenic was the body which appeared to have the greatest influence on that disease. Mr. McDonagh said that he had tested compounds of iron and of aluminium; an organic iron compound, "ferrivine," was non-toxic; a 1 per cent. solution was stable and did not oxidize in air. Occasionally typical shock or collapse followed the injection of 200 or 300 c.c.m. Experience gained with this compound had convinced Mr. McDonagh that the need for the use of a toxic metal like arsenic would soon no longer remain. In general, the symptoms of primary and generalized syphilis disappeared within four days after the second or third intravenous injection. Induration of chancres and dense infiltrated brownish papules resisted ferrivine as they did salvarsan, but disappeared within a fortnight if intramine were prescribed after the second or third injection. The theory of complement fixation was also touched upon, and Mr. McDonagh said that the Wassermann reaction did not afford an indication of the colloidal state of the lipid-globulin molecules or a measure of their number, but this knowledge was necessary both for diagnosis and for regulating treatment; thus it was no certain indication of active syphilis or that the patient required treatment. His emulsoid-suspensoid reaction overcame this difficulty.

On the suggestion of the PRESIDENT, it was decided to confine the discussion in the first instance to the chemical aspect of the work, and to discuss the clinical side later.

Professor BAYLISS asked for fuller explanation and experimental data with respect to a large number of Mr. McDonagh's statements. He considered that it was unfortunate that oxidation and reduction reactions should have been selected as the basis for the theory of chemotherapy. Of all processes taking place in the living body they were those the mechanism of which was most obscure. With regard to the use of the term "oxidase-reducase," it was impossible that the same system should be simultaneously both oxidizing and reducing in its action on a given body, hence the sense in which the expression was used appeared unclear. In speaking of the part played by lipid-globulin molecules, it had been stated that immunity and the formation of antibodies in the host was due to alterations in these molecules, while changes in similar constituents of the parasites led to their being killed. Professor Bayliss wished to know what proof there was of the existence of such changes and what their nature was. It had also been said that the development of immunity was due to an increase in size of these molecules, which increased their adsorptive power; but as adsorption had been shown to depend on surface, such an increase in size of the molecules would tend to diminish their adsorptive power. Professor Bayliss added that he could not follow the statements that specificity depended on amino-groups and that adsorption depended on active oxygen. Again, with reference to Mr. McDonagh's explanations as to why one substance, arsenic, should be toxic and another, sulphur, non-toxic, the speaker pointed out that these were fundamental differences the elucidation of which demanded knowledge not at present available.

Dr. C. H. BROWNING associated himself with Professor Bayliss's views and expressed a doubt whether in their present phase and without experimental proof the theories which had been advanced would contribute materially to the understanding of the subject by others. This, however, did not at all detract from the therapeutic results quoted. To be able to clear up with certainty and rapidly interstitial keratitis by an injection of intramine was an achievement of the first magnitude. It was highly interesting that the therapeutic value of this organic sulphur compound, which had been prepared upwards of thirty years ago, should now for the first time be recognized. The fact that this drug was closely similar to salvarsan in its molecular constitution was a striking testimony to the general soundness of the work of Ehrlich, who had not confined his attention entirely to arsenical compounds; work interrupted by his death had shown that the combination of salvarsan with copper yielded a

substance superior to salvarsan itself in the experiments which had been carried out.

In the course of further discussion Mr. J. WARD quoted investigations on the bactericidal action of various colloidal solutions, arsenic being exceedingly potent; he regarded this as in favour of Mr. McDonagh's theory; and Dr. F. H. TEALE pointed out that lipoids were not essential either to antigens or to antibodies. Sir MALCOLM MORRIS emphasized the necessity for a thorough discussion of the clinical aspect at an early date, in view of the great importance, especially at the present time, of deciding what therapeutic measures were the most efficacious in the treatment of syphilis. Lieutenant-Colonel HARRISON commented on the severe pain which he had observed to follow injections of intramine, and Mr. C. H. MILLS spoke of encapsulation of the unabsorbed drug.

Reviews.

CEREBRO-SPINAL FEVER.

As a result of their experience with cerebro-spinal fever during 1915 at the 1st Eastern General Hospital, Captains MICHAEL FOSTER and J. F. GASKELL have written an excellent practical account of the disease, its pathology, bacteriology, and management.¹

Beginning with a historical account, they note that cerebro-spinal fever made its first recorded appearance in the year 1805—at Geneva. Until 1902 it was comparatively little known in the United Kingdom; studies of its epidemiology emphasize the importance of human carriers in its spread, and Netter has given a most conclusive account of the way in which the disease was carried all over France, from the Pyrenees to the Rhine, by the French 18th Light Infantry during and after 1839.

The onset of the fever is generally marked by a rigor, followed by headache and vomiting in practically all cases; delirium often appears later, with restlessness and floccitation. That the height and duration of the fever give no criterion as to the severity of the case is remarkable; in the fulminating cases urgent dyspnoea is a highly characteristic sign. The authors describe four varieties of rash: a uniform macular rash, a fugitive erythema in different parts of the body, a petechial rash of a purple or copper colour at points of pressure, and a purpuric rash occurring in large purple spots or vibices, such as are common in all profound infections. Herpes was seen in 14 out of 39 patients. Inability to swallow was present in 6 out of 39 cases. The authors attach great diagnostic value to the presence of the sign first described by Kernig of Petrograd in 1884—contracture or flexion of the knee and hip when the patient is caused to assume the sitting posture; this is an early sign, present in all but the fulminating cases within twenty-four hours. Nystagmus was seen in 3 out of 39 cases; iridocyclitis leading to suppurative panophthalmitis occurred once in 91 patients; iridocyclitis was observed by Morax in from 3 to 6 per cent. of the cases in a Parisian epidemic. Implication of the respiratory and circulatory systems is said not to be common; constipation is almost the invariable rule, and haematuria without apparent permanent damage to the kidneys may occur during the acute stage.

Stress is laid upon the importance of early diagnosis. Kernig's sign is of great value here, more particularly as it points to the advisability of performing lumbar puncture. This operation, the authors state, should always be done under a general rather than a local anaesthetic; they find that no harm ever follows the general anaesthesia, but rather good, for the patient often gets several hours of peaceful sleep after it. From two to three ounces of cerebro-spinal fluid may be removed with advantage. When the fluid has been withdrawn, the further diagnosis rests with the bacteriologist.

From the clinical point of view the authors divide cases of cerebro-spinal fever into acute cases ending in death or convalescence within a fortnight, and subacute and chronic cases in which the issue remains doubtful for a longer period. In the chronic cases death, when it occurs, is due

to hydrocephalus, with increasing headache, perhaps a rigor, retention of urine, and unconsciousness. When hydrocephalus supervenes the optic discs show nothing beyond fullness of the retinal veins; Macewen's sign (a more resonant note on percussion of the skull about the pterion) may be of value in diagnosis here. No satisfactory treatment, surgical or otherwise, for this hydrocephalus is known.

As for the period of incubation in cerebro-spinal fever, the authors bring forward reasons for supposing that it does not surpass five days and may last only twenty-four hours. The prognosis is hopeless in fulminating cases; it is better the earlier treatment is instituted, and in patients aged between 23 and 30, and also in the later periods of an epidemic. The remote prognosis is usually good, as sequelae other than those pertaining to the nervous system are practically unknown; sequelae, too, are much rarer nowadays than they were last century. Treatment should consist in the early and daily repeated performance of lumbar puncture, fluid being allowed to run out until it issues at the rate of one drop in two or three seconds. The alleged danger from too rapid lowering of the pressure of the cerebro-spinal fluid may, it is stated, be disregarded. The authors performed lumbar puncture on thirty-two occasions in the course of sixty days in one patient, who made a complete recovery and returned to military duty. They note that the intrathecal injection of antimeningococcal serums has proved disappointing in their hands, as it has in the hands of many others. They have seen no good results from the exhibition of hexamine (urotropine). The headache of cerebro-spinal fever can be relieved by morphine only; there appears to be no danger of forming a morphine habit by giving it for this purpose.

About half the volume is given to the pathology, epidemiology, and bacteriology of the disease, the former being illustrated by eleven excellent plates, eight of them in colour. Many points of obscurity in the epidemiology of cerebro-spinal fever remain to be cleared up. Epidemic outbreaks are common in schools and among troops, but not, apparently, in other communities. In studying an epidemic one of the striking features observed is the disconnected or sporadic way in which the bulk of the cases occur. Infection may spread from case to case directly; more often it appears to be passed on by means of one or more carriers. No doubt the susceptibility of the individual is highly important here; it is also a very variable factor in the same person at different times, and it is often found that some comparatively slight illness (influenza, a sore throat) has preceded an attack of cerebro-spinal meningitis. Among a civilian population age appears to be a highly important factor, children and adolescents being particularly prone to infection; among soldiers fatigue does not seem to predispose to the disease. The disease is essentially one of the winter and spring, connected with rapid changes in the temperature and high winds. The authors come to the conclusion that the meningo-coccus is spread by being carried in the nose and throat of normal individuals, convalescent patients, and patients actually suffering from the disease, and is imparted to others by direct contagion—kissing, coughing, sneezing, and the like. It is impossible in this brief notice to give any account of the precautions to be taken to prevent the spread of cerebro-spinal fever, or of the pathology and bacteriology of the disease; the authors do ample justice to all of these subjects.

The book is excellently arranged, well written, and full of practical details that make it invaluable for the medical man and laboratory workers who have to deal with cases of cerebro-spinal fever. It may be most warmly recommended to their attention.

SWANZY'S OPHTHALMOLOGY.

THERE is, perhaps, no English textbook on the diseases of the eye that has enjoyed a wider popularity, and at the same time given its students a better introduction to the study of ophthalmology, than the work of Swanzy of Dublin.² Through ten editions it passed whilst it was directly the result of Swanzy's labours or in some later editions with the help of his colleague, Dr. Louis Werner.

¹ *Cerebro-spinal Fever*. By M. Foster, M.A., M.D., Captain R.A.M.C.(T.F.), and J. F. Gaskell, M.A., M.D., Captain R.A.M.C.(T.F.). Cambridge: The University Press. 1915. Imp. 8vo, pp. 230; 11 plates, 5 plans, 3 figures. 12s. 6d. net.)

² *Swanzy's Handbook of Diseases of the Eye and their Treatment*, edited by L. Werner, M.B., F.R.C.S.I., Sen. Mod. Univ. Dub. Eleventh edition. London: H. K. Lewis, 1915. (Demy 8vo, pp. 654; 9 plates, 261 figures. 12s. 6d. net.)

Now the eleventh edition is before us, and although the title of the work is the same, the task of editing the new edition has fallen solely to Dr. WERNER. All who knew Swanzy and his work will regret the loss of his genial presence and influence; but in the conduct of his textbook he has found a worthy successor in his former colleague, and the success of the past bids fair to be carried forward into the future. In appearance and general arrangement the new edition does not differ from the last, but much care has been expended on the revision of the work so as to bring it thoroughly abreast of the most recent gains in the diagnosis and treatment of eye conditions.

The chapter on glaucoma shows evidence of much care in revision. There is an excellent description of Schiötz's tonometer and the method of its use in determining the tension of the eye. In the same chapter the accounts of the several operations for chronic glaucoma are given with much lucidity. We particularly commend the manner in which these operations are arranged in chronological order; this has appreciable advantage to the student, who is able to see how the various procedures arose out of each other, one man's discovery leading to the improved technique of another. Not only is there a very real aid to understanding and memory in such a method, but there is the additional advantage that the credit of an advance in method is spread so far as is possible amongst those who helped to bring it about.

The chapters on the diseases of the retina have been rearranged. More attention has been given to the subject of retinal angio-sclerosis, and the result is a section that might well find a place in every textbook of medicine. Too few men in practice realize that there is no better means of determining the arterial condition of their patients than by the direct examination of a fine field of vessels in the fundus oculi. The judgement to be gained from such an examination is at least equal to and often better than that which can be gained by the use of a manometer.

Small details of practical value have not been overlooked by the editor. This is evidenced by the inclusion of a very useful note on the use and care of artificial eyes.

There are few English written books on eye diseases which can be recommended with greater certainty of satisfaction, both to the student and the practitioner, than the new "Swanzy."

NOTES ON BOOKS.

THE eighth edition of Southall's *Organic Materia Medica*³ has been brought up to date and revised by Mr. E. W. MANN, and is in accord with the *British Pharmacopoeia* of 1914. This well known book is designed for the use of teachers and students of pharmacology, chemists and druggists, and is a mine of valuable botanical, pharmacognostic, and chemical information. Dr. William Southall, author of the first edition, died many years ago; in the present edition his name is misspelt on the back cover, half-title page, and title page. *Sic transit!*

It is difficult to see what interest or amusement the general reader can find in an elaborate study of a born-tired, such as is presented by IVAN GONCHAROV in a novel entitled *Oblomov*,⁴ which C. J. Hogarth has been at the pains to translate into English. The thing is no doubt very well done, in that the description is very true to life, but was it worth doing? To study the processes of disease for the purpose of checking and overcoming them is a worthy and laudable occupation, whose repellent character is compensated by the object pursued; but to study the processes of disease for the purpose of depicting them to the morbid curiosity of the public, to revel and wallow in morbidity, is neither pleasant nor profitable, neither amusing nor instructive. If the study of *Oblomov*, if the description of his career from infancy to decrepitude threw any light on the causes of his malady or on the means of treating it, the book would have an undoubted value; but it does not. It is merely descriptive. It is a description of a subject that is morbid and unpleasant from beginning to end; and, worse than this, it commits the unpardonable literary sin—it is tedious. It is clean, indeed, and, as it belongs to the school of Zola, this is a merit to be recorded; but if it is not as dirty as Zola, it is

almost as tedious. There is evidently a market for the book, in Russia at any rate, and we can only say, in the well-worn phrase, that for those who like this kind of thing this is the kind of thing they will like. Incidentally it depicts the narrow, ignorant, limited life of the dwellers in a rural estate in Russia, and the explosion and turmoil that are produced in the family of the squire by the mere reception of a letter about nothing in particular.

In their elementary book on *The Body in Health*⁵ Messrs. O'SHEA and KELLOGG have endeavoured to present modern physiology in a form attractive for pupils in elementary schools. It is written quite clearly, and in a style alternating between that of the popular press on the one hand and the nursery on the other. A special chapter is given to "The Body's Enemies," which are, oddly enough, said to be tobacco and alcohol. Yet this is a book that may be recommended for use in Sunday schools and the like.

MEDICINAL AND DIETETIC PREPARATIONS.

"Intramine" in Syphilis.

As is well known, the late Professor Ehrlich put forward the "side-chain" theory, according to which the reaction between drug and parasite is due to the nature and conformation of portions of the molecules, so that one fits to the other somewhat in the same way as a key fits a lock. Mr. McDonagh dissents from this view, and some account of his views is given in a report of a discussion in the Dermatological Section of the Royal Society of Medicine published at p. 591. It is asserted that oxidizing enzymes have their action increased by metals, but that oxidation can also be increased indirectly by stimulating reduction by means of non-metals. Many of the statements made appear to be highly speculative, and in the present state of our knowledge not capable of proof; the practical outcome is that, in Mr. McDonagh's view, the alternate exhibition of certain metallic and non-metallic compounds may be expected to be a useful means of treating syphilis and some other diseases; in particular, attention is directed to di-ortho-amino-thio-benzene,

a compound to which Mr. McDonagh has given the name "intramine." This is a yellow crystalline powder, which is suspended in oil and injected intramuscularly; it is said to be quite non-toxic, and therefore capable of being given in large doses, and to be more efficient than salvarsan at certain stages in cases of syphilis. Compounds of aluminium and iron, known as "aluvine" and "ferrivine," which may be used alternately with intramine, are also described. In certain cases treatment by intramine is reported to have given excellent results; and the clinical effects of the drug are to be discussed at another meeting of the same section. Intramine is made and sold by the British Drug Houses, Ltd., Graham Street, N., and supplied in ampoules containing 1-gram of the solid in 10 c.cm. ready for injecting. Since it is not affected by the action of the air, it is not necessary for the whole contents of an ampoule to be used up at once.

Sanitas-Sypol.

We have recently received a sample of sanitas-sypol, a disinfectant manufactured by the "Sanitas" Company, Ltd., and intended to replace lysol for use in surgery. It is a clear fluid, perfectly miscible with water to form a bright transparent solution, and containing, according to our analysis:

Combined alkali, calculated as potassium hydroxide	3.32 per cent by weight
Cresols	48.5 per cent by weight.

No free alkali is present. These characters show that it is an excellent preparation, well adapted to the purpose for which it is put forward.

Indian Thymol.

Messrs. Smith, Stanistreet and Co., 9, Dalhousie Square, Calcutta, have submitted to us a sample of Indian thymol, which we understand they are now in a position to produce in large quantity. The sample in question is excellent in colour and odour, complies with

³ Southall's *Organic Materia Medica*. Revised and enlarged by E. W. Mann, B.Sc. Lond., F.I.C. Eighth edition. London: J. and A. Churchill, 1915. (Demy 8vo, pp. 410. 7s. 6d. net.)

⁴ *Oblomov*. By Ivan Goncharov. Translated from the Russian by C. J. Hogarth. London: G. Allen and Unwin, Ltd. 1915. (Cr. 8vo, pp. 317. 6s.)

⁵ *The Body in Health*. By M. V. O'Shea and J. H. Kellogg. Health Series of Physiology and Hygiene. New York: The Macmillan Co. 1915. (Cr. 8vo, pp. 332; illustrated. 3s. 6d. net.)

the requirements of the *British Pharmacopoeia 1914*, and altogether compares very favourably with the German product obtainable before the war. So far as quality is concerned, therefore, the product of this firm should have no difficulty in permanently replacing thymol manufactured in Germany.

MEDICAL AND SURGICAL APPLIANCES.

MR. H. S. SOUTTAR has designed, and Messrs. Allen and Hanburys have made, a glove to maintain the extended position of the hands and fingers in paralysis of the extensor muscles, and the relaxation of those muscles essential to their recovery. A leather armband above the elbow is connected by a detachable leather strap to the

wrist of a stout leather glove. Inside the glove elastic bands pass from the wrist to the top of each finger. On contraction of the flexors the fingers and wrist can be flexed and the hand used.

ROYAL MEDICAL BENEVOLENT FUND.

(Continued from p. 559.)

THE following is a continuation of the summary of cases relieved by the Committee at its meeting in March:

Widow, aged 47, of M.D. Edin. who practised at Glasgow and died in 1912. Applicant was left unprovided for with seven children. The older ones are now married, and unable to help, and the four younger children are at school. Only permanent income £22 from other charities. Tries to supplement this by taking in boarders, but unsuccessfully. Relieved four times, £72. Voted £20 in twelve instalments.

Daughter, aged 65, of M.R.C.S. Eng. who practised in London and died in 1853. Left totally unprovided for, and has worked in various ways to try and support herself, but was unable to provide for her old age. Her income now from a charity and friends totals £28, and she tries to supplement this by poultry-keeping. Relieved three times, £30. Voted £6 in twelve instalments.

Daughter, aged 67, of M.R.C.S. Eng. who practised in North Devon and died in 1903. Was left totally unprovided for, and her health is exceedingly unsatisfactory, which has prevented her from working. Her only income has been a few shillings weekly from friends. Previous help, £14. Voted £12 in twelve instalments.

Widow, aged 46, of L.S.A. Lond. who acted as ship's surgeon and died in 1912. Was left with three children, aged 8 to 24. The eldest is unable to assist, and the others are too young to do anything. Applicant is now working as a typist at £1 a week, but finds it insufficient to keep four persons. Relieved four times, £18. Voted £12 in twelve instalments, and referred to the Guild.

Widow, aged 66, of surgeon in the Army Medical Service who died in 1888. Only income a War Office pension. Was operated upon six years ago for cancer and had breast removed. Has four children, but all married, and none able to help. Wants a little help to furnish spare bedroom, so that she might take in a paying guest. Relieved once, £16. Voted £5, through the Guild.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.

THE ROYAL MEDICAL BENEVOLENT FUND GUILD.

The Royal Medical Benevolent Fund Guild has issued its sixth annual report. It was presented to the annual general meeting at the Mansion House on February 21st by the Lord Mayor, as reported in the *JOURNAL* at the time. All cases helped are either qualified medical men, their widows and children, or unmarried daughters of such practitioners. The Guild not only makes gifts in money and kind when satisfied that they are needed, but also gives personal service, and for the conduct of this part of the work has a special visiting committee. It is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand

clothing and household linen. The class of clothes most wanted are such as are suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

NOTIFICATION OF PREGNANCY.

By J. W. BALLANTYNE, M.D.,

EDINBURGH.

THERE has been some talk of late of the desirability of introducing notification of pregnancy into Great Britain, and there have even been whispers of its being made compulsory. Before, however, any such proposals are accepted by the medical profession, it will be well to inquire what benefits are expected to flow therefrom.

Pros.

I. If the country had a system of compulsory notification of pregnancies it would be put in possession of figures respecting the number of infants on the way, and when these were compared with the number of births of living children, it would be made aware of the antenatal losses incurred. It would know what percentage of the starters in life's antenatal race had failed to breast the tape; it would also, with the help of the returns as to premature births obtained under the Notification of Births Act, have an inkling of the proportion of competitors who fell out before the last lap was entered upon. This information would doubtless come as a shock to some, it would awaken all to a better realization of the amount of potential lives that are being lost annually, and it would enable a few to say, "I told you so."

II. It would impress upon the general public, and perhaps specially upon the woman's part of it, the emphasis which is now at last, after many years, being laid upon pregnancy, for it would be taken for granted that some good purpose was intended to be served, beyond the obtaining of an estimate of the forthcoming crop of babies. It would therefore be necessary to follow on with a clear statement of the advantages which would accrue to the women notifying their pregnancies, of the benefits likely to be conferred upon the infants thus antenatally taken stock of, and of, possibly, some financial aid to be given at or after the confinement, or, better still, during the few weeks which preceded that event.

III. It would undoubtedly be a stimulus to the study of all matters relating to the hygiene and pathology of pregnancy and antenatal life, and if this stimulus produced its expected effect there would be a great increase in the frequency of antenatal treatment, and the scope of pregnancy supervision would be widened. In the long run there would be saving of lives to an unknown but certainly not inconsiderable extent.

IV. In the fourth place, it might serve to check the frequency of abortions and the use of abortifacient means.

Cons.

On the other hand, any such system of notification, especially if it were made compulsory, would arouse opposition and give origin to difficulties of many kinds.

I. The necessity for the preservation of at least a certain amount of privacy in intimate home affairs would be pleaded. During the continuance of the war and with individual responsibility and national success each playing a part, the inhabitants of these islands are prepared to write "*fiction pro tem*," across the adage "an Englishman's house is his castle"; but the compulsory notification of pregnancy would not be proposed as a temporary but as a permanent measure, and in the intimacy of its application it would produce disquiet in the public mind. A public which, in certain places at least, is ready conscientiously to object to vaccination would be with difficulty led to put itself in the hands of the enumerators of this novel census. Neither can it be thought that "the men at the front" would easily be persuaded of the necessity of so great a degree of paternal solicitude on their behalf and in their absence.

II. There would be irritating difficulties in the details and methods of the notification. The diagnosis of early pregnancy is not very easy, and for the notification to be of real value it would require to be made early so as to check third and fourth month abortions. Perhaps it

could be called a provisional diagnosis and notification, but then its value would be greatly lessened, for sufficient care would not be taken to ensure accuracy. Then, again, what harmless and unobjectionable means would be taken to enforce notification, and what penalties would be proposed for non-compliance? Could women doctors be supplied in sufficient numbers to carry out the examinations if a demand was made for them? Would the doctors be asked to do this also gratuitously? And so on.

III. It is unnecessary to force on such legislation and introduce so many new difficulties into health affairs, for events are already spontaneously moving in the direction aimed at. Many of the advantages which may be claimed as likely to flow from compulsory notification are already in process of being gained, slowly, it is true, but surely, and with increasing facility, by means of an education of the public in the nature and hygiene of pregnancy (through the work of the Women's Co-operative Guild, antenatal consultations, books on expectant motherhood, and other bodies or means), in the necessity of propagation in a progressive nation, in the care of young and especially of neonatal life, and in a hundred other matters, amongst which the making plain of the causes, dangers, and prevention of the venereal diseases must be reckoned as an effective part. It may be confidently expected that the present falling birth rate and the rising death-rate (without taking into account the loss of life abroad) will not fail to keep the increased and increasing value of antenatal life prominently in the public mind.

Suggestions.

Let us by all means "lengthen our cords and strengthen our stakes" in every direction in such educational ways and plans. Let us, as a profession, welcome as coadjutors eminently fitted for the task the various women's associations which are imbued with a sense of the value of infantile life and are in touch with women of all classes, but especially of the working and middle; let us as doctors aid them by accepting the responsibility of supervising pregnancies from their earliest weeks, by establishing more and more maternity hospitals, centres, and homes with all the essential component parts of the prematernity system attached thereto, and by putting the best of our special knowledge and skill at the call of the women passing through pathological pregnancies and labours.

Let the midwives act in like fashion.

Let us accept as watchword the Parisian phrase of these days, "Let every necessitous woman who is pregnant or who is nursing a young child have the social, legal, and medical protection to which she is entitled as a member of a civilized society: let no mother be overlooked and no infant forgotten." Let us study what was done by Pinard and others for infant life in Paris, even when the tide of battle was daily rolling nearer and "the Medes were at her gates."

When some eight years ago Mr. Eden Phillpotts asked why we should not have a "State department for the unborn," I heaved a sigh and said to myself, "Because we should only be laughed at for our asking"; I am not so certain of the sequent amusement now. Pinard has said—and it is not unlikely that the phrase may remain after the war is over—"notwithstanding an intensive puericulture, babies are not being made and cared for as are munitions."

If there is to be compulsory notification of pregnancies, let it come spontaneously from the women's organizations; but in the meantime let us, as a medical profession, accept all the voluntary notifications which are made to us by expectant mothers, and watch over the pregnancies thus entrusted to our medical care; let us do our best to popularize correct notions of the nature, risks, and hygiene of pregnancy, and let us freely give our assistance to all agencies which have as their aim the comfort and health of expectant mothers and the welfare of young infants at the breast or in the womb. If the Insurance Commissioners can see their way to make grants to necessitous mothers before their labours, as is being done in Paris, so much the better. But let us be up and doing.

The programme of the *Office central d'assistance maternelle et infantile* in Paris in the early weeks of the war began with these appealing words:

PARISIENS,

LES PÈRES SONT À LA FRONTIÈRE;

DEFENDONS LES MÈRES ET LES PETITS ENFANTS!

À LEUR AIDE ET VITE.

The response was immediate; fresh milk for infants and hospitals through the military authorities; money to enable expectant and nursing and necessitous mothers to rest from hard bodily toil; and a supervision of mothers and infants which caused a decrease in infantile and maternal morbidity and mortality such as could hardly have been thought possible. We are in straits not quite so pressing, but the situation is full of depressing possibilities—

Qui non est hodie,
Cras minus aptus erit.

He who is not ready to-day will be less so to-morrow.

THE OPHTHALMIC HOSPITALS OF EGYPT.

THE third annual report of Mr. A. F. MacCallan, the Director of Ophthalmic Hospitals in Egypt, is a record of steady advance in work of a most excellent character. Not even the sacrifices which the department has made owing to the war has stayed the increase of its activity. Two medical officers left for military service and two fully staffed and equipped tent hospitals, together of 150 beds, were detached for the treatment of wounded Turks on the line of the Suez Canal. Nevertheless, the number of patients increased in the year by 9,456 and the attendances of out-patients by 141,745.

During the ten years ending with 1914 no fewer than sixteen ophthalmic hospitals have been opened; all except two are endowed. Of the total cost of provision of these hospitals only £17,000 has been contributed by the Government, £49,000 was obtained by gift, public subscription, or local taxation. This is apart from the Cassel fund. The hospitals are not costly; for £4,000 a hospital with a commodious out-patient department and beds for 16 patients can be built. This accommodation suffices for a daily clinic of 200 to 300 patients. Besides these there are travelling hospitals, large tents, with accommodation for 6 to 10 in-patients with attendants.

Four provinces still lack hospitals and they are too poor to provide them for themselves. Two of these provinces should have specially built dahabia hospitals, for the terrain is along the river. When a hospital is provided the Government will maintain it.

The outstanding feature of the clinical report is the note on glaucoma. Glaucoma simplex was found to be present in 2.3 per cent. of the patients seen. The cause of this prevalence is as yet undecided, though it is suggested the anatomical condition of the eye among the Egyptians, with frequently a very small cornea, is the predisposing factor. The figures for the three past years are as follows:

	1912.	1913	1914.
Glaucoma:			
Acute	3	12	17
Subacute	10	17	23
Chronic	829	902	574
Absolute	282	217	1,147
Operations for glaucoma:			
Iridectomy	60	28	25
Trephining with iridectomy	152	317	428

Care has been taken to follow up the cases of trephining to note if there is any danger of intraocular infection through the thin conjunctival covering of the new vent; only one case was found, and that in a boy of ten who had suffered from increased tension in an eye with adherent leucoma; even here there was a history of injury to the eye just preceding the final disorganization of the organ.

In the year 7,784 bacteriological examinations for the diagnosis of acute ophthalmias were made. The gonococcus heads the list with 43.6 per cent.; next come the Koch-Weeks bacillus with 19.5, and the Morax-Axenfeld bacillus with 16.6 per cent. Diphtheria accounts for only 0.96, and the streptococcus for 0.03 per cent. Gonococcal conjunctivitis is rarely accompanied by gonorrhoeal

urethritis. Infection appears to be from eye to eye. Chronic attacks are seen in cold weather, the acute being mainly seen in the hot weather. The organism, therefore, persists during the winter months on the conjunctiva of various sufferers without the necessity of a sojourn on the urethral membrane. Interesting charts are given showing the relationship of the incidence of the various forms of conjunctivitis to the meteorological conditions.

In the section dealing with the ophthalmic inspection of schools note is made of the campaign against trachoma. The general incidence in the schools is still high, being given as 92 per cent. Taking the more infective stages of the disease, there has been a distinct reduction in the incidence. From 95.5 per cent. in 1907 it has now been reduced to 11.7 per cent., and at the end of a school session it is brought still lower.

Conjunctivitis accounts for the greater number of blind eyes; 76 per cent. are referable to it either directly or indirectly.

THE EDUCATIONAL MENU CARD.

THE Educational Department of Public Health of the city of New York has opened a lunch-room for its employees at head quarters.

The object of this is primarily to provide a wholesome luncheon at cost price; secondarily, to educate the patrons in the subject of food and nutrition by the objective teaching of the lunch-room. The enterprise is being financed by the employees themselves; the city is put to no expense in its maintenance. The menu for the opening day is before us, and it sets forth not only the dishes but the quantity which is served and the calorie and protein value of each portion. Specimen lunches furnishing a balanced ration are given, one at a low and the other at a high cost.

The low cost luncheon is as follows:

	Price.	Quantity.	Calories.	Protein.
Cream of asparagus soup...	2½d.	½ pint	230	Grams, 7.0
Salade a la Santé ...	4d.	Average helping	370	2.0
Glass of milk ...	2d.	7 oz.	160	7.0
Apple pie ...	2½d.	One-sixth of pie	300	4.0
Whole-wheat bread...	—	2 slices	140	5.5
Butter ...	—	½ oz.	120	—
	11d.	—	1,320	25½

The high cost lunch contained:

	Price.	Quantity.	Calories.	Protein.
Cream of asparagus soup...	2½d.	½ pint	230	Grams, 7.0
Roast beef ...	10d.	4 oz., lean	140	30.0
Mashed potatoes ...	—	Average helping	150	4.0
String beans ...	2½d.	2 h. tbsp.*	110	0.5
Salade a la Santé ...	4d.	Average helping	370	2.0
Apple pie ...	2½d.	One-sixth of pie	300	4.0
Black coffee ...	1½d.	1 cup	—	—
Sugar ...	—	2 cubes	100	—
Whole-meal bread ...	—	2 slices	140	5.5
Butter ...	—	½ oz.	120	—
	1s. 11d.	—	1,520	53.0

* h. tbsp. = heaped tablespoonful.

The articles of food ready every day and those special for each day are set out with cost, quantities, calories, and protein values, so that the guest can select and calculate the nutritious value of his own lunch. We learn the following facts:

	Quantity.	Calories.	Protein.
Ginger bread ...	2 oz.	220	Grams, 3.5
Ice cream ...	2 h. tbsp.*	190	5.0
Tea or coffee with 2 cubes of sugar and milk	1 cup	80	—
Ditto with sugar and 1 oz. cream	"	160	2.3
Cocoa ...	"	185	9.0
Baked apple ...	1 med. size	130	0.5
Ditto with 1½ oz. cream	—	250	2.0
Whole-wheat bread sandwiches with cheese	1½ oz.	340	16.5
Ditto with ham	"	280	16.5
Egg (one) and ham	—	370	23.0
Potatoes (fried)	Average helping	120	3.5
Boiled rice ...	3 h. tbsp.*	330	8.0

The menu card not only gives the guest all this information but affords appropriate mottoes, such as "Since Eve ate apples much depends on dinner" (Byron); and what a subject for conversation it gives! If every hostess would only add the calorie and protein value to her dinner menu card there would be no more trouble in making conversation, and distress for the shy and nervous partner. Discussion as to how we are going to make up our physiological allowance—dare we exceed it and by how many calories? how do the food values compare with those of Mr. Grundy's dinner? is our hostess right in her protein value for the quail? and surely the calorie worth of asparagus is too high for the portion we have been given?

We measure the miles we walk, the temperature of our rooms and bath, the medicine we take, why should not we have the exact measure of the food we eat? The quack pill and salts vendors make their fortunes out of the gross guzzling habits of the nation. Feed up your strength, avoid the slightest exposure to cold—these are tenets held as fast as parts of a religious creed. They lead to digestive disturbances and impoverished health. The metabolism is reduced, excess food is eaten and not utilized, and the bowels become the seat of bacterial fermentations, which lead to chronic intoxication and a host of complaints.

How many clerks, shopmen, etc., have in the last nine months been changed by military service from pale, dyspeptic men, below par, unjoyous, into magnificent healthy soldiers full of the perfect enjoyment of life? This is due to hard physical labour, and exposure to cold and wind, which enormously increases the metabolism and the appetite and favours the complete digestion and utilization of the food. For many sedentary workers the appetite overruns the bodily needs. For these the menu card, with the calorie and protein values set out, would be useful. Not only does the over-eating work much harm to the national health, but the economic waste is enormous. Let us, then, in these scarce and dear times of war, spread the use of the Educational Menu Card.

LARVA MIGRANS, a creeping eruption of the skin, first reported by Robert Lee in 1874 and investigated by Dickinson, Tilbury Fox, and Duckworth, was traced by Sokolow to the *Gastrophilus haemorrhoidalis*, a horse fly. Dr. F. C. Knowles, of the University of Pennsylvania, has demonstrated (*Journ. Amer. Med. Assoc.*, January 15th, 1916) its histologic features and followed up the burrow and the larva in the epidermis. One of the two cases he records occurred in a girl aged 20 months; there were areas of the size of a palm of serpiginous gyrating lines on both nates and on the pubes. Treatment with nitric acid having failed, all three tracts were excised. The larva, however, made a fresh progression four days later at the edge of the excision on the left buttock, and in twenty-four hours advanced 2 in., burrowing down towards the lower edge of the mons veneris on the left side. A second excision was followed by permanent cure. The tracts differed from those seen in scabies. Under the microscope the burrows were explored and at some points the larva was detected. In almost all cases these passages ran in the upper portion of the rete, and the diameter of the burrow varied from 0.25 mm. to 0.75 mm.

British Medical Journal.

SATURDAY, APRIL 22ND, 1916.

THE CONTROL OF VENEREAL DISEASES.

On April 14th the President of the Local Government Board informed a deputation from the National Council for Combating Venereal Diseases that the Treasury was prepared to provide the necessary grant to carry out the recommendations of the Royal Commission with regard to the provision of facilities for diagnosis and treatment. The grants would cover 75 per cent. of the cost incurred by local authorities. It was not proposed to create special hospitals for the treatment of venereal diseases, as it was felt that treatment would be carried out more efficiently and with less danger of prejudice at the existing general hospitals.

The Royal Commission on Venereal Diseases entertained the hope that benefit would be derived from a wide public knowledge of the dangers of untreated venereal disease and the certainty of a real cure if the treatment of the disease was undertaken at the earliest stage of the infection. The Commission, indeed, laid great stress on its expectation that the report would give this desirable publicity. The hope is in process of realization. In the current issue of the *Edinburgh Review* (April, 1916) is an article which deals with the Report and the evidence given to the Commission in a broad-minded fashion. In quoting from the article we confine our attention to parts which emphasize certain findings of the Commission and certain points as to which there was some disagreement or total silence.

The article sets out with a statement emphasizing the urgency of dealing with these grave evils. Its opening sentence is: "The issue of the final Report of the Royal Commission on Venereal Diseases is an event of national importance, deserving the attention of all well-wishers of humanity, even in the stress and strain of a world-war. It may be doubted whether even this war at its finish will have shortened a larger number of lives and decreased the physical and mental efficiency of a larger number of persons than has venereal diseases during a single generation." Such a statement in such a place may help the nation to realize the urgency of the need for dealing with the evil. The stringent comment of the report on the evils of quack treatment is pointed by a quotation from the evidence of Dr. Johnstone, a medical inspector of the Local Government Board, who stated "that medical men in various parts of the country informed him that they were rarely consulted until the patient had spent some weeks in the hands of a herbalist or chemist, or in trying some advertised cure." Exception was taken by one at least of the Commissioners to the proposal to keep infected patients in Poor Law infirmaries until they are cured. On this the article makes the following comment: "The patients in question are usually inveterate prostitutes who have become diseased to an extent which disqualifies them from plying their unhappy traffic, and who consequently are destitute. Even with the knowledge that they will be detained until well, such women must enter the infirmary; and persons of practical experience appear to regard it as

certain that the exercise of powers of compulsory detention would not be likely to have a deterrent effect in preventing these women from accepting treatment. Such 'ins' and 'outs' at present are a serious scourge to the community. In maritime towns, for instance, such women, when still highly infectious, 'take their discharge' when a large ship arrives in port, returning as soon as their horrible business slackens! The amount of mischief thus done is incredible to those who have not come into actual contact with it; and at present there is no effectual remedy for it."

The final paragraphs of the article deal with prophylaxis. The report proper did not mention this matter, but a reference to it appears in an appendix. The article reads: "It is well known that the use of simple measures within one or two hours after exposure to infection will, in most instances, prevent the occurrence of the disease. . . . The Commission carefully refrained from expressing any opinion upon either method of guarding against the disease. The importance of the matter cannot, however, be ignored. Both at home and abroad our soldiers are grievously infected with venereal disease. . . . Short of imprisoning every woman who approaches a military camp and absolutely cancelling all military leave, it is impossible to begin to prevent soldiers from running the risk of venereal infection. Nor would even these impossibly drastic measures touch the case of soldiers living in billets. The seriousness of the matter is fully recognized by the military authorities, and lectures are given on the horrible character of the risks that a man runs in consorting with immoral women, but the results are disappointing. Therefore the question arises whether, in the interests of their health, of the health of their wives and of their unborn children, and also of the military strength of the nation, it is not desirable to give our soldiers the opportunity of guarding themselves against disease. It is not suggested that the soldiers should be in any way encouraged to indulge in irregular intercourse, or that anything should be done which would give them the idea that the military authorities look with tolerance upon irregularities. But the evil is so grave that the case is very strong indeed for putting into the hands of the soldier the means which will enable him to protect himself."

In another part of the article we find the following: "The experience of the world proves conclusively that in no country has the dread of venereal diseases ever prevented the existence of irregular sexual relationships. Few people who are able to look facts in the face can hold the belief that the world will ever reach a stage when the rules of monogamy are strictly and universally observed. But if that stage should ever be reached it is certain that the change will be due to moral causes, not to materialistic fear of specific diseases." Do the people who refuse to 'condone vice' really think that it is justifiable to allow the race to be saturated with syphilis while waiting for an epoch of universal purity?"

One more paragraph we will quote for its bearing on the present difficulties of the country: "Venereal diseases form a scourge which, with the possible exception of tuberculosis and cancer, in time of peace is chief among the Captains of Death and Disease. In war the ravages of venereal diseases form an even more serious calamity. Large numbers of our soldiers are rendered inefficient for considerable periods by these diseases, and this to an extent which seriously handicaps our military position. So far no recent figures as to the amount of these diseases among our troops have been published, but it is well known that the amount is serious, and that in several parts of the

country there are large hospitals which contain no patients except venereal patients."

We have preferred to deal with this important article mainly by way of quotation because we think that by the publication of the report of the Royal Commission the matter has now been put into the hands of the public and of Parliament to find solutions for the problems raised. As to the seriousness of the effects of these diseases there are no two opinions among members of the medical profession, who would probably generally accept the truth of the opinion Sir William Osler expressed on the Commission that "of the killing diseases syphilis comes third or fourth." If to this we added a mental estimate of the number of conceptions prevented by the consequences of gonorrhoea we might be justified in promoting venereal diseases to a worse eminence.

PILIMICTIION.

PILIMICTIION, or the passage of true hairs in the urine, is a phenomenon of very rare occurrence. It was noted by Hippocrates in his *Aphorisms*, with the erroneous explanation that the hairs were excreted by the kidneys. Galen and many medical writers after his day referred to pilimiction, often adding strange hypotheses or theories to account for the production of the hairs passed. It was not until 1849 that the true explanation was given, by the French surgeon Reyer. He found that the hairs originated in dermoid cysts, and reached the urine by the rupture of such cysts into the bladder. Naturally the other contents of the cysts would enter the bladder, so that teeth, carious teeth, bones, and fragments of other tissues might be found in it; but these do not seem, as a rule, to be passed in the urine by the patients to whom this unusual accident has occurred. Carraro¹ quotes from the literature to show that 56 cases have been recorded in which a dermoid cyst ruptured into the bladder—40 in women, 16 in men. Pilimiction was observed in 27 of these—16 of them women, 11 men; but owing to imperfection in the records considerable doubt exists with regard to the propriety of including 6 of these 27. In 21 of those without pilimiction, hairs were found inside the bladder. The patients varied in age between 2 months and 71 years; the hairs passed might be as much as 6 in. in length. The origin of the dermoid cyst in many of the patients remains wrapped in mystery for want of thorough examination either by laparotomy or obduction. In the case of the female patients, however, there is good reason for believing that the cysts almost always originated in the ovary. Exceptionally the dermoid cysts may have originated in the wall of the bladder itself, which is very rare, or, more probably, in the paravesical tissue and rectovesical ligaments. In any case these cysts grow within the pelvis, and by processes of growth, inflammation, and degeneration become adherent to the adjacent wall of the bladder, and finally rupture and discharge their contents into that organ. Carraro passes lightly over the vexed question of the mode in which such dermoid cysts come into existence. Some, at any rate, appear to be embryonic inclusions, the result of the cutting off of epidermal structures by maldevelopment and their inclusion deep inside the body. Others, particularly those containing mesodermal and endodermal as well as ectodermal tissues, represent fetuses (teratomas or embryomas) that are really abortive twins of the patients unknowingly harbouring them.

Whatever its origin, the cyst may become infected with bacteria by way of the blood or the lymph stream; it is thought that the gonococcus is often the infecting agent in these cases, but in Werth's patient it was proved to be the *Bacillus typhosus*. Rupture of the inflamed dermoid cyst into the bladder naturally gives rise to cystitis, with its train of local and general symptoms and its disturbance of micturition; a simultaneous rupture into the peritoneal cavity may take place, and even septicaemia or pyaemia may be set on foot. Carraro gives a full account of a case of pilimiction under his own observation. It occurred in an otherwise healthy stout married woman of 40. For a few months before she presented herself at the hospital she had complained of painful and increasingly frequent micturition. She came into hospital with acute fetid cystitis and incontinence of urine; a stone was found in the much-contracted bladder, and was removed under local anaesthesia by suprapubic cystotomy. It was the size of a walnut, and composed of short reddish hairs 1 or 2 cm. long, surrounded and bound together by calcareous matter. The woman had anuria for three days after the operation, and faeces appeared in the purulent urine on the sixth day, but this soon cleared up. A fortnight after the operation short hairs thickly incrustated with lime salts were being passed in the urine, and the cystitis reappeared. Cystoscopy showed that the dermoid tumour opened into the lower surface of the bladder to the left of the middle line. A few weeks later the bladder was opened again under spinal anaesthesia, and the dermoid cyst excised; a month after this second operation the patient was discharged cured. The tumour, 6 cm. long and from 1 to 2 cm. thick, consisted of typical hairy skin and subcutaneous connective tissue, with many vessels and very large sweat glands in it, some of the ducts having developed into hydrocystomas; both dermis and epidermis showed oedema and inflammatory infiltration. Carraro points out that there was nothing in the history of the case to show either whether pilimiction had actually occurred before the patient entered hospital, or how the acute cystitis originally arose; it may have been primary and have set up the infection of the dermoid cyst, or it may have been secondary to infection of the cyst from elsewhere. He believes that the communication between the cyst and the rectum had been established before the patient came to the hospital. He concludes his paper with four pages of advice to surgeons who may in the future be confronted by cases of pilimiction.

THE HORRORS OF WITTENBERG.

It was to be expected that an attempt would be made by the German Government to nullify the effect of the exposure of the horrors of the Wittenberg prison camp contained in the report issued by the British Foreign Office last week. A semi-official telegram from Berlin says that "the report is a repetition of former charges which were refuted when a committee of American doctors gave expression to their satisfaction at the sanitary and hygienic conditions of the camp." On April 13th Sir Edward Grey said in the House of Commons that, according to a statement of the Prussian Ministry of War issued to the press on February 14th, nearly all the camps in Germany had been visited on behalf of the United States Embassy and reports issued as soon as they were received. The staff of the Embassy had, it was added, been increased by four medical men to enable more frequent visits to be made to the camp. This, it may be presumed, is the "committee" referred to in the German denial.

¹ N. Carraro, *Il Morgagni*, Milan, 1915, Arch. ivii, 247.

But, as it is expressly stated that they were not allowed to visit the Wittenberg camp during the period covered by the recent report, the evidence of the American doctors, assuming that its purport is correctly given, cannot be accepted as a refutation of the charges made by the British Committee. We have strong proof of the truth of the charges in a report by Dr. Bert W. Caldwell, Director of the American Red Cross Sanitary Mission to the German prison camps, who, at the request of the United States Ambassador at Berlin, with the official approval of the German Government, made a thorough inspection of the camps at Münster, Wittenberg, Altdam and Gutersloh in November, 1915. His evidence is all the more convincing as his report, which is published in the March number of the *Military Surgeon*, the organ of the Association of Military Surgeons of the United States, is very favourable to the German authorities. Dr. Caldwell found the administration of the prison camps "humane, just, and of high order." But there was one exception. The name of the camp is not given, but there can be no difficulty in identifying it from the following description: "Typhus exanthematicus made its appearance in two or three of the camps, causing frightful morbidity and mortality in one. This regrettable occurrence was due to the inhumanity of the prison commandant, who, when typhus broke out in the barracks among the Russian prisoners, insisted upon the English, French, and other prisoners occupying the same barracks with the infected Russians, until some 800 of the prisoners became infected with the disease, and about 300 of them died. This epidemic, when the commandant was shorn of a part of his authority and effective measures were established within the camp was soon controlled." The epidemic came to an end in July, and Dr. Caldwell's inspection was made in November, when it is admitted that the state of things had greatly improved. But, as we said last week, as long as the care of sick prisoners is left to the tender mercies of a medical officer who has shown himself so inhumane as Oberstabsarzt Dr. Aschenbach we must feel misgivings as to their treatment. Every man of proper feeling will share the indignation expressed by Sir William Milligan in the letter published at p. 606, and we hope that a time will come when fitting punishment will be meted out to a man who has disgraced a profession of mercy in a manner which has excited the abhorrence of the civilized world. We are doubtful, however, whether the wholesale expulsion of Dr. Aschenbach's fellow countrymen from the honorary membership of our societies would be the most dignified or the most effective way of punishment for a man so destitute of decent feeling. Moreover, although German "intellectuals" have cut a sorry figure in the eyes of those of other countries, there is evidence that many members of the profession who have the misfortune to belong to that nationality have shown all the best qualities which are expected in the doctor in their treatment of wounded and sick enemies. In regard to the inspection of prison camps, we cannot help sharing the suspicion expressed by Professor J. A. Morgan that the Germans have hoodwinked the American Ambassador. "They stamp out the horrors in one camp and let him see it; and meanwhile these horrors break out in another camp, which he does not see." Unhappily the British Government, with all the experience of the last twenty months before it, does not seem even now to have learnt how the Germans make war. On April 17th Sir Edward Grey expressed regret that he and his colleagues had underestimated the brutality of our enemies. They had no suspicion of the horrors of the Wittenberg Camp, or of the gross and criminal cowardice of the German medical staff in abandoning their duties to those under their charge. So confiding were they that they did not think of demanding an independent examination of the camp. It is pretty certain that such a demand would have been met with a refusal, for during the prevalence of the epidemic

the Germans allowed no kind of communication as to the conditions existing at Wittenberg. There was too much they could not conveniently allow the outside world to know. Sir Edward Grey added that the Government had no reason to suppose that other typhus-infected camps in Germany were treated in the same way. It is deplorable that they should not have informed themselves more fully as to a matter so directly affecting the welfare of British prisoners. The evidence comes from too many sides and is too uniform in purport to be set aside by any semi-official denial. We need only refer to the account of the typhus-outbreak at Gardelegen given by Major P. C. Davy and Captain A. J. Brown in the *BRITISH MEDICAL JOURNAL* of November 20th, 1915, and to Dr. F. Léonetti's record of his experiences during similar epidemics at Cassel and Langensalza, a summary of which was given in the *JOURNAL* of March 18th, p. 421.

INFANT AND MATERNAL WELFARE.

THE Carnegie United Kingdom Trust proposes to prepare a comprehensive report upon the present position in regard to infant and maternal welfare, with special reference to the provision made or in immediate contemplation in various sanitary areas. To this end a schedule of questions has been drawn up and is being issued to medical officers of health of the larger districts of England and Wales. It has been drafted in a form which, it is hoped, will minimize trouble for each medical officer in preparing the information relating to his district. The schedule is on large paper, with room for the answers, and is divided into seven main sections. In Section A (general condition of the area) it is asked that statistical and other data may be given under a number of heads, including housing accommodation, birth-rate and infant mortality-rate, the diseases most fatal to infants, and maternal mortality. Section B refers to activities of local sanitary authorities and asks for particulars as to the staff of the M.O.H., the administration of maternity benefit and of the Children's Act, and as to the organization of infant welfare and maternity hygiene under the heads of "ante-natal," "natal," and "post-natal." Section C asks for particulars with regard to voluntary agencies, such as infant welfare centres, schools for mothers, hospital provision, and district nursing associations. Section D (Poor Law) asks for facts as to lying-in accommodation, and Section E (midwives) for particulars as to the relation with the municipality and the municipal staff and with voluntary agencies. Section F inquires how education in mothercraft is dealt with, whether by the education authority or by voluntary agencies, and how it is given to mothers, to young women, to schoolgirls, in school, and at day nurseries. Finally, there is a blank sheet for general observations by the M.O.H. We have endeavoured to give a general notion of the scope of the inquiry, but have not sought to enumerate every heading. The trustees desire to obtain the fullest information, in order that they may be in a position to decide what steps, if any, can be taken by the Carnegie Trust, and generally to assist in the solution of the problems which arise. The forms and all correspondence should be addressed to Dr. E. W. Hope at the offices of the Public Health Department, Municipal Buildings, Liverpool. We have no doubt that, if the inquiry is welcomed by the medical officers of health, as it ought to be, and as we feel sure as a rule it will be, a great deal of useful information will be brought together, and it is certain that under Dr. Hope's supervision it will be analysed in the very best possible manner, and the conclusions to be drawn from it judiciously worked out. The questions as to antenatal organization are full, and this fact is proof of the growing importance attached to this department of preventive medicine. It is asked, for instance, whether any special plan exists in a district for ensuring provision of medical advice for expectant mothers

at, for example, antenatal clinics conducted by gynaecological specialists, by ordinary medical practitioners, or by nurses, and it is also asked whether facilities exist for pathological and bacteriological examinations in relation to ophthalmia neonatorum, syphilis, and abnormalities. Under the heading "natal" there are questions as to the existence of any scheme in operation to provide for medical help in emergencies under the Midwives Act, and what provision is made for nursing cases of puerperal fever at home or in institutions.

THE CAMPAIGN AGAINST VENEREAL DISEASE IN GERMANY.

THE numerous articles on venereal diseases which have recently appeared in the German medical press fall into two groups—those that deal with preventive, social, and legal methods, and those that confine themselves to the purely medical aspects. Dr. F. Schaefer has discussed¹ the possibilities of continuing after the war the drastic regulations introduced on April 1st, 1915, by Hindenburg, who made it an offence in his army, punishable with two to twelve months' imprisonment, for women, whether they were prostitutes or not, who knew they were suffering from venereal disease, to engage in sexual intercourse with civilians or the military. Proof that they had exposed others to this danger was sufficient to ensure a conviction, even though their conduct had not actually led to spread of the disease. Dr. Schaefer expressed the opinion that, though in practice convictions would seldom be secured except when venereal disease had been conveyed, the threat of punishment, even when there was no proof that infection had occurred, would be a powerful deterrent to many women. He suggested that this regulation should be legalized after the war, and extended to include male as well as female offenders. Professor Blaschko has drawn attention² to the Danish and Norwegian practice, according to which medical men are prompted to induce their patients to sign a paper acknowledging that they have been informed as to the nature of the disease from which they are suffering, so that they may not afterwards plead ignorance should they convey the disease to others. Professor Blaschko has elaborated the scheme he put forward at the XIIIth International Medical Congress in London. He is not in favour of fines and imprisonment so much as of enforced medical control and treatment. Under the heading, "Is it really quite impossible to render prostitution physically harmless?" Professor Neisser has dealt³ at considerable length with various reforms he would like to see introduced in the regulation of prostitution and the prevention of venereal disease. Among many other suggestions he advocates more compulsory medical supervision and treatment and less police supervision, which is apt to entail unnecessary hardship. In dealing with the medical aspects of venereal disease Professor Zeissl⁴ has urged the early abortive treatment of syphilis by the combined use of salvarsan and mercury. In twenty-seven cases he succeeded in aborting primary syphilis completely. In view of the frequency of venereal disease among German soldiers on active service, he anticipates extensive infection of the civilian population when the soldiers are discharged after the war. To prevent this disaster he considers that before any soldier is sent home Wassermann's reaction should be applied, and a bacteriological examination made of any urethral discharge. Only when the absence of venereal disease was established by a medical expert should he be allowed to return home. Evidently Professor Zeissl would insist on compulsory treatment for the soldiers found suffering from venereal disease, but on this point he is not explicit.

TUNGSTEN.

THREE is considerable fascination in tracing the widening uses to which metals are put in the service of man. Tungsten affords a good example of fresh virtues being discovered in a very old servant. For many years tungsten has been mined in various parts of the world, and the powdered metal was mainly utilized in the processes of steel hardening, more especially for what are known as high-speed tools. The ultimate refining of the metal presents no particular difficulties, yet it appears that almost all the refining has in recent years been done in Germany. Mr. Hughes has recently driven home the lesson to be learnt by any industry which is dependent upon other countries for its necessities, and the criminality of such a procedure for the people of an empire which lacks nothing beneath the sun. Tungsten is a widely distributed element, and occurs chiefly in the ores wolfram or scheelite; to this latter mineral the name tungsten, signifying heavy stone, was given by the Swedes. We gather some interesting data as to the world's output of this material from a recent memoir of the geological survey on tungsten and manganese ores, the first of a series of *Special Reports on the Mineral Resources of Great Britain*. From it we learn that the total output of tungsten ores the year before the war was about 8,000 tons; Australasia, Europe, America, and Asia (Burma and Japan) all contributed, the last named accounting for about one-third of the total output. The quantity mined in England, chiefly in Cornwall, is roughly about 200 tons a year. Some of the new uses found for tungsten may be very briefly mentioned. The discovery of a successful method of welding the metal opened the way to the modern wire filament lamp, for by this process the metal, usually very brittle, is rendered quite ductile. This invention, which was made by Dr. Coolidge, led him to make further investigations, and the happy result was the new x-ray tube which bears his name. The novel features of this tube are not, of course, dependent upon the materials used, but some recent endurance tests on the tube described by Dr. Coolidge show to what a degree the qualities of tungsten contributed to the remarkable results recorded. To cite but one performance, we may note that the tube was allowed to run continuously for forty-two hours at 70,000 volts and a current of 100 milliampères, the heating current through the tungsten spiral only varying from 4.50 to 4.58 ampères. Its very high melting point and high atomic weight render tungsten the metal of choice as the anticathode of x-ray tubes, and the use of it in this connexion is increasing. In common with many other metals the open arc of tungsten is rich in ultra-violet radiation, and it may prove a useful addition to the other sources of this type of radiation which are already at the disposal of the medical profession. It is satisfactory to learn that the world-patents for the welding of tungsten are in the hands of a British firm, the British Thomson-Houston Company, Ltd.

THE HEALTH OF GERMAN EAST AFRICA.

THE German Colonial Office in Berlin published last year medical reports of all the German protectorates for the year 1911-12.¹ The sanitary staff in German East Africa consisted of 44 sanitary officers, 3 Government doctors, 11 sisters, and 68 junior sanitary officers. Thanks to the vaccination during the three previous years of nearly two and a half million persons, that is, about a third of the total population of the colony, only sporadic cases and slight epidemics of small-pox occurred. Plague was imported into the colony through Zanzibar, but was limited to a few cases. Other cases were, however, observed in the interior, which somewhat resembled plague, but their nature was obscure. Towards the end of the year under review plague broke out in a malignant form in one district. The war

² *Deut. med. Woch.*, January 6th, 1916.

³ *Ibid.*, No. 47, 1916.

⁴ *Berl. klin. Woch.*, January 10th, 1916.

¹ *Muench. med. Woch.*, February 1st, 1916.

against rats was carried on by putting a price on their heads, by the employment of rat catchers, and by a liberal use of poison. There was considerable rise in the incidence of malaria, and among Europeans malaria and blackwater fever accounted for a third of all the diseases treated and for a sixth of all the deaths. The sum of 350,000 marks was spent on sleeping sickness. The original plan of concentrating the sufferers in permanent camps had gradually to be abandoned, and efforts were concentrated on disinfecting the infected districts. Atoxyl was found to be the most potent drug, and was curative in about 15 to 20 per cent. The arrest of this disease in the district of Lake Victoria was traced by the medical authorities to the measures they had adopted. About Lake Tanganyika, however, the state of affairs was far less satisfactory. There was no change in the incidence of leprosy, typhoid fever, dysentery, and relapsing fever, but in the northern district small epidemics of cerebro-spinal meningitis occurred. Whooping-cough was also prevalent in some districts, and tuberculosis, which had previously been almost unknown, showed an alarming increase, especially in the coastal towns and commercial stations of the interior. Bilharziosis was prevalent in the southern area. The control of prostitution had failed to reduce the incidence of venereal disease.

A WORTHY MEMORIAL.

EXTENSIVE alterations and additions have been in progress at the Chester Royal Infirmary for some years, and on April 15th Lord Bryce opened an ophthalmic theatre and two adjoining wards, for which tenants on the Hawarden estate and friends had subscribed, as a memorial of the late Lieutenant William Glynn Charles Gladstone, squire of Hawarden, Lord Lieutenant of Flintshire, and M.P. for Kilmarnock Burghs, who was killed in the trenches in France on April 13th, 1915. Lord Bryce said that Mr. Gladstone, as Lord Lieutenant of the county when war broke out, had devoted himself with earnestness to recruiting, and in the course of doing so it was borne in upon him that when he was urging others to come forward to save their country he ought not to stay behind himself. He trained himself to be an officer, went as lieutenant to France, and within a fortnight the end came. "Never," Lord Bryce went on, "was there a time when so many of our best and noblest young men have gone from us, willingly, because they felt it to be their duty, and never was there a time when their parents had shown such an example of uncomplaining patience. Never had England shown herself worthier of the greatest tradition of her greatest days than she had in these last months. An England that could do this was an England worth fighting for. One of the most famous men of antiquity, in pronouncing a funeral oration over his Athenian fellow-citizens who had been killed in war, said: 'When the young men are taken out of the city spring is taken out of the year.'"

ANNUAL CONGRESS OF THE OPHTHALMOLOGICAL SOCIETY.

THE annual congress of the Ophthalmological Society of the United Kingdom, the mother of all ophthalmological societies in the world, will be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W., on the last three days of the first week in May. On Thursday, May 4th, the president, Mr. Walter H. Jessop, will give the opening address at 10 a.m., and afterwards various papers will be read. Among them we notice one by Mr. Affleck Greeves, which will contain observations on a series of trephined eyes examined microscopically; another by Mr. Richardson Cross on severe kerato-iritis cured by tuberculin; and a third by Mr. J. B. Story on implantation of fat after enucleation. In the afternoon a discussion will be opened at 2.30, by Mr. Herbert Parsons and Mr. A. L. Whitehead, on foreign bodies in the eye and orbit, with

special reference to prognosis and treatment. On Friday morning, May 5th, at 10 a.m., Mr. J. B. Lawford and Mr. S. H. Browning will open a discussion on the treatment of syphilitic eye affections by the newer methods, and in the afternoon there will be a clinical meeting at the Central London Ophthalmic Hospital, Judd Street, W.C., when a number of interesting cases will be demonstrated, including one by Dr. N. Finzi, in which recurrent sarcoma of the orbit was successfully treated by radium. On Saturday morning, May 6th, other papers will be read. During the congress a collection of drawings, pathological specimens, etc., will be on view in the Bowman Library at the Royal Society of Medicine, and members desirous of exhibiting are requested to communicate with Mr. Stephen Mayou, 30, Cavendish Square, W. Members wishing to read papers, show cases, or take part in discussions, are asked to communicate as soon as possible with Mr. Elmore Brewerton, 84, Wimpole Street, W.

Medical Notes in Parliament.

War.

German Treatment of British Prisoners.

ON April 17th Captain Douglas Hall asked a question with regard to the treatment of Private A. C. Tulley, Royal Marines, with ten years' service, who died at Millbank, weighing only 5 stone. The Home Secretary said that there was no record of Private Tulley's weight at the time of his death, but it appeared from his statements that he was confined in the camp at Döberitz, where the men were covered with lice, and that after working in the wet he had no means of drying his clothes and could get no underclothes. In July, 1915, he got rheumatic fever through going on daily fatigue duty, getting wet through, and having no change. He was sent to hospital, and after five weeks was convalescent. He was sent to another camp, Dyrotz, about 7 kilometres from Döberitz. He had to carry all his kit on the march, and broke down and was never well afterwards. A little later he was put into hospital at Döberitz, where he had no treatment at all, and had to depend upon an English prisoner, one of the patients. They had no drugs. When he arrived in this country he was in an advanced stage of consumption and extremely emaciated. He died in hospital a fortnight after his arrival. The medical board which reported upon his condition stated that it was due to exposure, insufficient food and clothing whilst a prisoner in Germany. Tulley himself stated that the conditions in the camp had much improved before he left it, and other reports confirmed this. Improvements seemed to have resulted from the efforts of the American Ambassador. There was no record of any other prisoners of war released from Döberitz camp having died since their return to this country.

In a written reply to Mr. Malcolm, on April 17th, Sir Edward Grey said that the Germans permitted no kind of communication, either by letter or orally, as to the condition of Wittenberg camp during the many months that the camp remain unvisited, owing to the prevalence of typhus, by the American Ambassador at Berlin or by any of his staff. The British Government had no suspicion of the horrors that were going on there, or of the gross and criminal cowardice of the German medical staff in abandoning the duties they owed to those under their charge. Neither our allies—whose prisoners in the camp were far more numerous than ours—nor we demanded independent medical examination of the camp, and on behalf of the Government he could only express profound regret that it had so underestimated the brutality of our enemies. It was only right to add that the Government had no reason to suppose that other typhus infected camps in Germany were treated in the same way.

Steel Helmets.

In reply to Colonel McCalmont, who asked how soon a sufficient number of steel helmets would be available for every soldier whose duty took him into the trenches, Mr. Tennant said, on April 13th, that he had acquainted himself with the state of the supply, but did not propose to inform the House or the enemy about it in

detail. The active resumption of hostilities would not find the troops in the trenches unprovided in this respect. Not only had there been no diminution in the supply, but it was being accelerated. In a written answer to Mr. Annan Bryce, on April 17th, Dr. Addison said that the steel helmets (of which large quantities had already been supplied to the British troops in France and of which adequate supplies were assured) possessed higher protective properties than the French pattern. It was desirable that a uniform design should be adhered to, and it was not considered advisable to place orders in France because it was not known that steel of the requisite standard could be obtained in France; it was most important to maintain the reliance which, he was informed, our troops now placed in the helmets.

Army Medical Service.

On April 12th Mr. McNeill asked whether some of the most eminent specialists in the various branches of surgery had been for a long time during the war employed in field ambulances or otherwise where their special qualifications were wasted; and whether it was proposed to take steps to insure that doctors with special experience in different branches of medicine and surgery who had joined the R.A.M.C. should be utilized to the best advantage. Mr. Tennant said that the supply of efficient operating surgeons in military hospitals at home and abroad was fully adequate. It was necessary that a certain number of younger surgeons should be employed with field ambulances. Every effort was made to use the services of medical men joining the R.A.M.C. for such duties as their special acquirements and professional limitations best fitted them, but it was impossible to allow each individual to select the work which he considered himself most competent to undertake. Mr. McNeill suggested that Mr. Tennant had not observed that his question referred to eminent specialists and not to younger officers, and inquired whether Mr. Tennant was prepared to deny that eminent specialists in surgery had been employed in very inferior work. Mr. Tennant said that he was quite prepared to believe that eminent specialists had occasionally, when they were employed abroad, to do somewhat trivial duties. That must be part of every campaign; whereupon Mr. McNeill exclaimed "Not at all," but Mr. Tennant said that he did not agree. He thought it was inevitable in the ordinary routine of carrying on a great campaign that it might fall to the lot of the most eminent to do the most trivial duties. The army retained the services of these most eminent specialists, and if they had to employ them in that way occasionally he was very sorry, but it was part and parcel of the difficulty of carrying on a great campaign. Mr. McNeill next asked whether, with a view to economizing the supply of medical men available for the army, steps would be taken to provide that general practitioners should be, so far as possible, employed in part-time work in hospitals, or in looking after the health of troops quartered in the neighbourhoods where such practitioners lived, so as to release for duty men who had volunteered for whole-time service, thus obviating the necessity of asking an unnecessary number of men to take commissions in the R.A.M.C., whereby the supply of doctors for the civil population at home was in danger of being unduly depleted. Mr. Tennant said, in reply, that general practitioners were already being largely employed in local military work. Every effort was made to protect the needs of the civil population for adequate medical attendance, and the War Office was receiving in this connexion the advice and assistance of representatives of the civil medical profession and of the various Government departments concerned.

Pensions and Grants: Temporary Rank.

Mr. Tennant stated, on April 13th, that in the case of an officer having permanent rank and higher temporary rank, his widow got the benefit of the temporary rank should the officer die from wounds.

Weekly Rest for Munition Workers.—In reply to a question by Mr. Pratt, on April 17th, Dr. Addison said that Mr. Lloyd George was keenly alive to the importance of securing to munition workers an unbroken rest period of not less than twenty-four hours weekly. A circular recommending this weekly rest period (preferably on Sundays) had been sent out on December 7th, 1915, to all controlled establishments. This was followed by an inquiry addressed to each establishment, and a committee

was appointed to deal systematically with the subject. There were many practical difficulties in the way of securing entire abolition of Sunday labour, but substantial progress had been made, and out of 2,383 firms from whom particulars had been obtained, 1,440 were not now employing any Sunday labour. Of the firms which worked on Sundays, 60 had notified the department that all workers were provided with a rest period of at least continuously twenty-four hours each week. Constant and pressing attention was being given to the matter, and it was hoped that the number of firms employing no Sunday labour would shortly be largely increased.

Massage in Military Hospitals.—In reply to Major Chapple, Mr. Tennant, on April 12th, said that specialists in massage who held colonial qualifications were not being denied employment in military hospitals because they did not hold an Almeric Paget diploma; in fact, he was informed that there was no such thing as an Almeric Paget diploma. Six months' training was required before a masseuse could be accepted, unless her education took place some time ago. This was the rule for the qualification of masseuses in civil life.

Verandahs for Consumption.—On April 13th Major Astor asked how many military and Territorial hospitals had verandahs for the purpose, *inter alia*, of providing treatment for consumptive soldiers, and approximately the number of soldiers who could be accommodated and treated on these verandahs. Mr. Tennant replied that soldiers suffering from pulmonary tuberculosis were discharged from the service and admitted to sanatoriums under arrangements made with the Insurance Commissioners and the Local Government Board. It was true that a special type of hut had been designed with verandahs for the treatment of some cases, though not necessarily for consumptive patients. No data as to the number of patients who could be accommodated in existing verandahs were available.

Duration of Treatment in Military Hospitals.—In reply to Major Astor, Mr. Tennant said on April 12th that hospital treatment was continued until a cure was effected, or until it was obvious that the soldier would not be medically fit to remain in the service. In no circumstances was a soldier discharged from hospital (except to special institutions) unless he was able to leave without detriment to his health.

Hernia.—In reply to Mr. Jowett, Mr. Tennant stated, on April 12th, that carefully selected men suffering from slight hernia, if properly fitted with a truss, might be passed for general service. It was not anticipated that active service would incapacitate or harm these men.

Infant Welfare.—On April 13th Mr. King asked the President of the Local Government Board if he would issue instructions to local authorities that an expenditure not exceeding £d. in the £ might be judiciously undertaken, even in war time, on promoting infant welfare and combating infant mortality; and whether the Government was prepared to supplement such expenditure when efficiently carried out on approved lines. Mr. Long replied that he had already encouraged local authorities to undertake work for the promotion of infant welfare, and Parliament had been asked to vote money for furthering their efforts. He did not think that anything could be gained by an instruction of the kind suggested. Mr. King then asked whether it could be suggested to local authorities that health visitors should be, as far as possible, employed by local authorities in the proportion of not less than two for every 1,000 births; and whether provision was being made for the 1,600 health visitors who, under such arrangements, would be necessary to carry through a national policy of preserving infant life. Mr. Long said that the suggestion was included in a memorandum which had been circulated to all the medical officers of health. In a written answer to Mr. King, on April 17th, the President of the Local Government Board stated that the amount of the grant distributed in aid of maternity and child welfare work in 1915-16 to towns with a population over 250,000, including London, was £15,404 to local authorities and £4,809 to voluntary agencies. Grants amounting to £351 were paid to rural district councils, and a great deal of the sums of £6,130 paid to county councils and £2,475 paid to voluntary agencies in counties were for the benefit of rural areas. Grants were paid in 1915-16 to 308 local authorities in respect of expenditure on schemes for maternity and infant welfare incurred in the financial year ended March 31st, 1915. Since that date several new schemes and additions to existing schemes had been approved, but the actual number was not readily available.

MR. ARTHUR DU CROS, M.P. for Hastings, has generously promised a gift of £7,000 to the Extension Fund of the London (Royal Free Hospital) School of Medicine for Women, thus completing the £30,000 for which appeal was made.

THE WAR.

ARMOUR.

(From a Correspondent in Northern France.)

It must be at least ten months since the French first began to use helmets, and quite six since the appearance of a *poultu* in a helmet ceased to excite any attention, even at places far distant from the front. It is, in fact, rather the other way. The majority of all French soldiers seem now to wear helmets, the chief exception being certain classes of men rarely if ever employed in the fighting line, and those belonging to regiments provided with a cap which is a badge of national import. Of the latter the *Chasseurs d'Afrique*, who wear a kind of high, straight-sided, woolly fez, are a good example.

The helmet is made of thin steel enamelled a dull blue, and presents an outline which suits the majority of French faces. It is surprisingly light, and makes quite a comfortable headdress. That this is the case may be concluded not only from what the men themselves say, but also from the fact that they do not hasten to take off their helmets when sitting about off duty in cafés and elsewhere.

Among British troops the use of helmets has only recently become other than tentative, and it is still mainly at certain parts of the line that they are to be seen in any considerable number. It has been arranged now to issue them wholesale as rapidly as possible, but even when this has been done it seems likely that the British helmet will, like trench boots, remain for the most part a front line article of attire. It lacks the grace of the French helmet, and is too heavy to be willingly worn on all occasions.

On the other hand, the British helmet is considered to be better designed to meet its direct purpose than is the French; it has a wide downward sloping brim, and thus protects the side and back of the neck and the temples and upper part of the face as well as the top and sides of the head.

This breadth of brim makes the crown look shallower than that of the French helmet, but a more real difference is that the British helmet has a smooth round top, while the crown of the French presents a prominent ridge tapering centrally backwards. This ridge was initially intended to strengthen the helmet, but being hollow and open at one end it also provides a means of ventilating its interior. In addition, it adds to the headdress a style that the English helmet lacks. But it is open to question whether these advantages are not fully outweighed by the fact that a fragment which would glance harmlessly off the smooth round British crown, might be stopped by this ridge on the French helmet, and inflict on the wearer a stunning jar, if not worse.

Unlike the French helmet, the British recalls nothing ever seen in collections of the armour worn in early European warfare. It does, however, bring to mind the pith hats worn by civilians in certain parts of India, and resembles these all the more closely because like them it does not fit close. It stands away from the head about one third of an inch all round, the weight being borne by a padded leather band fixed to the inner side of the surrounding steel by a series of indiarubber buffers, each about the thickness of a lead pencil, and about 1 in. long. This detail of construction constitutes perhaps the most important difference between the British and French helmets. The buffers are capable of diffusing and neutralizing the force of a blow, which, falling on the closely-fitting French helmet, would be conducted direct to the brain-pan.

The heaviness of the British helmet is a drawback, and it is possible that its protective effect would be increased by lowering the brim still further, so as to guard against bomb fragments or other missiles rising upwards from a point within a yard or two of the wearer, but there is already clear evidence that its introduction is a step of great value.

On the basis of the experience of some recent wars head wounds have been written down as accounting for 15 per cent. of all casualties, but data obtained a month or two ago by the medical authorities out here suggest that in trench fights, at any rate, the numerical importance of head wounds really is considerably greater. The figures indicated, in fact, that even when cases surviving long enough to reach the casualty clearing stations are alone

taken into account the proportion of wounds of the head, neck, and face to all wounds must be in the neighbourhood of 25 per cent.

Consequently there can be no doubt of the military value of any measure proved to be capable of reducing that ratio materially without interfering with the fighting capacity of the men.

One of the measures tentatively adopted has been the use of helmets, and its efficacy has been put beyond doubt by some other figures that the medical authorities secured in connexion with a fight of some magnitude about the beginning of March, when the British troops engaged were wearing helmets. All the cases admitted at one particular casualty clearing station were analysed, and the resulting figures show that the number of penetrating gunshot wounds of the head was equal to less than $\frac{1}{4}$ per cent., while the total number of fractures of the skull was well under 1 per cent. of all injuries.

The number of casualties on which these percentages are calculated was in the neighbourhood of 1,000—a total sufficiently large to exclude the inference that the paucity of fractures of the skull was merely an accidental circumstance.

Furthermore, there was the direct evidence supplied by the helmets of a number of men who had been struck on the head by missiles of various kinds, but who had nevertheless sustained no injury more serious than a scalp wound. Indeed, some men whose helmets had been dented or pierced or broken were not even aware they had been struck on the head. It was clear, in short, that though the helmets were by no means bullet-proof, they commonly offered such resistance that a missile which succeeded in penetrating them thereby lost most of its force.

The success of these helmets seems to open up the question whether other armour formerly used could be usefully reintroduced. To settle this it must first be decided how much additional weight an average soldier can carry without materially lessening his activity, and what part of the body other than the head most requires protection. In this connexion it is to be remembered that a missile which anywhere else in the body or limbs would produce nothing more than an unimportant flesh wound might easily bring about a rapidly fatal result if it struck a man anywhere between the xiphoid cartilage and the pubes.

EYE INJURIES AND BLINDNESS IN THE GERMAN ARMY.

Eye Injuries and Diseases.

DR. W. UHTHOFF, consulting ophthalmologist to the 6th German Army Corps,¹ has analysed the statistics of about 600 eye casualties in a reserve hospital to which he was attached as consulting ophthalmologist. The proportion of non-traumatic to traumatic casualties was as 1 to 1.7. The most common of the inflammatory lesions of the cornea was keratitis dendritica—a herpetic condition; it constituted 25 per cent. of all the inflammatory diseases of the cornea, and was attributed to the strain and exhaustion of war. Though these patients remained long under treatment, the ultimate results were usually good; in some cases ordinary treatment was supplemented by superficial cauterization of the diseased cornea. In few cases was the disease apparently due to traumatism. *Ulcus serpens* was observed only in about 1 per cent., and the relative rarity of this disease was, no doubt, due to the soldiers being in the prime of life, and free from such complaints at the time of mobilization. Another disease found to be unexpectedly rare was gonorrhoeal conjunctivitis, only one case of which came under Dr. Uthoff's care. Yet, of other gonorrhoeal complications there was an abundance in the neighbourhood. Trachoma accounted for only 5 per cent. of the 600 cases, although the territory (Russia and Galicia) from which Dr. Uthoff drew his patients was supposed to be extensively infected with this disease; from the amount of scarring present in most cases it was judged that the condition must have been of old standing. This relative rarity of trachoma was also noted by Dr. Uthoff's colleagues, and he attributes it largely to the high standard of efficiency in the Army Medical Service. Iritis, which constituted about 8 per cent. of all the non-traumatic

¹ *Berliner klinische Wochenschrift*, January 3rd, 1916.

diseases of the eye, was due to syphilis in every third case, to rheumatism in every third case, and to unknown factors in the remaining third. Cases of nyctalopia represented about 3 per cent. of the non-traumatic diseases of the eye; they could also be grouped in three equally large classes: nyctalopia due to organic disease of the retina, and hereditary and idiopathic nyctalopia. There were 252 cases of direct injury to the eye, and the sight of one eye was totally lost in 46 per cent. The proportion of total blindness to blindness on one side only was as 1 to 10.

Care of Blind Soldiers.

Dr. Unthoff has dealt with the care and education of blinded soldiers in another article.² He expressed the opinion that the wisest and ultimately the most humane course was to keep them for a time in skilled hands and in surroundings calculated to stimulate them to build up a new mode of life which would give them occupation and relative financial independence. He thought it probable that the institutions established before the war would be able to cope with the demands of the army by a system of extension if every district undertook the care of its own men. He insisted that it would be folly to squander large sums, voluntarily subscribed, on new palatial residences, when so much more could be done by leaving the matter in the hands of district institutions already familiar with the education of the blind. He also objected strongly to the slipshod management of homes for the blind by amateurs incapable of carrying out a systematic course of education. It was all very well for these philanthropists to pamper blinded soldiers with concerts, lectures, and other festivities, but the time would come, after the war, when enthusiasm for the blind would die out, leaving them dependent on others' efforts for amusement and occupation. Dr. Unthoff considered it inadvisable to educate blinded officers together with their subordinates; and as the pensions for officers were as much as eight times as large as those given to privates, the former were not so dependent on education in an institution as privates. In the case of married privates, the best plan would be for their homes to be near an institution in which they could benefit from systematic teaching while living at home. Dr. Unthoff touched on the subject of the marriage of blinded soldiers by patriotic, tender-hearted women with great sympathy, and he also urged on his audience the need for providing the blind with large Braille libraries.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

Lieutenant-Colonel Cedric Barkley Prall, Bengal Medical Service, died at Mhow, Central India, on April 5th. He was the youngest son of the late Richard Prall, town clerk of Rochester, born on March 8th, 1870, was educated at St. Thomas's Hospital, and qualified as M.R.C.S. and L.R.C.P.Lond. in 1892. Entering the L.M.S. as surgeon-lieutenant on January 30th, 1893, he became surgeon-captain on January 30th, 1896, major on January 30th, 1905, and lieutenant-colonel on January 30th, 1913. He served on the north-west frontier of India in the campaign of 1897-98, when he was present in the operations at the Samana range and in the Kurram Valley during August and September, 1897, and in the defence of Fort Gulistan, being mentioned in despatches in G.C.O. No. 1417 of 1897; also in the Tirah campaign of the same years, when he took part in the actions of Chagru Kotai and of the Sampagha and Arhanga passes, the reconnaissance of the Saran Sar and action of November 9th, 1897, the operations in the Waran Valley and action of November 16th, in the operations at and around Dwatoi and action of November 24th, and in the operations in the Bara Valley, December 7th to 14th, 1897, receiving the frontier medal with three clasps.

Major Ernest Brice, R.A.M.C.(T.F.), died at Swansea on April 5th. He was educated at Mason College, Birmingham, and took the Scottish triple qualification in 1896. After serving for some time as a medical inspector of schools he went into practice at Swansea, where he was medical officer and public vaccinator of No. 5 district, Swansea Union. He was an examiner, lecturer, and honorary life member of the St. John Ambulance Association, also of the British Red Cross Society, medical

referee to several insurance companies, and honorary secretary of the Swansea Medical Society. On December 25th, 1911, he took a commission as captain in the 3rd Welsh Field Ambulance, was promoted to major last year, and was in command of the 3/3rd Welsh Field Ambulance.

Lieutenant John James Mackintosh, R.A.M.C., has died of gastritis at the age of 31. He was the eldest son of the late Mr. Donald Mackintosh of Stornoway and Mrs. Mackintosh of Inverness. He received his medical education at the University of Glasgow, and took the M.B., Ch.B. in 1908. When war was declared he was in practice in Johannesburg, Africa, and served with General Botha's forces in the South-West African campaign. He subsequently returned to this country and received a commission in the R.A.M.C.

Died of Wounds.

Lieutenant Malcolm Edward Ball, R.A.M.C., is reported as having died of wounds on April 10th. He was the fourth son of Edward Ball of Lewisham Hill, Blackheath, was educated at Guy's, and took the M.R.C.S. and L.R.C.P.Lond. in 1908 and the M.B. and B.S.Lond. in 1909. After filling the posts of clinical assistant, assistant house-surgeon, out-patient officer, and house-physician at Guy's he went into practice at Emsworth, in Hants, where he was honorary medical officer of the Emsworth Victoria Cottage Hospital and surgeon to the Havant Red Cross Hospital. He joined the army as a temporary lieutenant in September last.

Wounded.

Captain C. R. Woodruff, R.A.M.C.(T.F.).
Captain H. W. Greig, R.A.M.C.(T.F.).
Captain J. M. McKerchar, R.A.M.C., Special Reserve.
Captain G. J. Bowen, R.A.M.C. (temporary).
Lieutenant J. Coutts, R.A.M.C. (temporary).
Lieutenant W. G. Macdonald, R.A.M.C. (temporary).
Lieutenant J. M. Mackenzie, R.A.M.C. (temporary).
Lieutenant M. G. Pettigrew, R.A.M.C. (temporary).
Lieutenant R. R. Pirrie, R.A.M.C. (temporary).
Lieutenant N. McCall Smith, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Dobie, William Murray, Lieutenant Royal West Kent Regiment, son of Dr. Herbert Dobie, of Chester, killed in action on April 9th, aged 19. He was educated at Marlborough and at Caius College, Cambridge, got a commission on October 3rd, 1914, and had been at the front since last May.

Dobson, Harold Pierce, Captain Worcestershire Regiment, third son of Mr. Nelson C. Dobson, F.R.C.S., of Clifton, reported killed in the casualty list published on April 15th, aged 34. He got his commission in 1903, served in Ireland, Ceylon, South Africa, and India, was for three years adjutant of the second battalion, and for three years adjutant of the Simla Volunteers, becoming captain on September 22nd, 1914. He married in India the eldest daughter of Colonel Hore. His brother, Major M. C. Dobson, was killed at Loos last September.

Gross, Geoffrey Yates, Captain Royal West Kent Regiment, second son of the late Charles Gross, F.R.C.S., killed in action on April 9th. He was educated at Clifton College and at Oxford, and joined the army as second lieutenant on August 15th, 1914, became lieutenant on March 23rd, 1915, and captain last December.

Powell, Scott, Captain Royal Welsh Fusiliers, youngest son of Sir Richard Douglas Powell, K.C.V.O., M.D., died of wounds on April 4th, aged 30. He was educated at Charterhouse and at Christ Church College, Oxford, where he took the B.A., and was admitted a solicitor in 1912. He joined the Inns of Court O.T.C. before the beginning of the war, got a commission on August 22nd, 1914, and was promoted to captain on January 15th, 1915. He had served in Gallipoli from June till the end, and took part in the withdrawal from both Anzac and Cape Helles.

Nichol, John, Lieutenant Royal Scots Fusiliers, and Flying Officer, Royal Flying Corps, second son of Dr. Nichol of Margate, accidentally killed while flying on April 5th, aged 22. He was educated at Charterhouse, got his first commission in 1912, and joined his regiment at Pretoria. He was promoted to lieutenant on November 12th, 1914, served at the front from February to October, 1915, and then went through the training for the Flying Corps, qualifying as flying officer in January last.

NOTES.

HONOURS.

THE King has appointed the undermentioned medical officers to the Orders stated in recognition of their devotion to duty at the camp at Wittenberg, Germany, during the typhus epidemic which prevailed there from February to June, 1915:

C.M.G.—Major Harold Edgar Priestley, R.A.M.C.

D.S.O.—Captain Alan Cunliffe Vidal, R.A.M.C.; Temporary Captain James La Fayette Lauder, R.A.M.C.

² Berl. Klin. Woch., January 24th.

The President of the Scottish Women's Hospitals for Foreign Services has received intimation that the Crown Prince of Serbia, during his recent visit to London, had bestowed decorations upon the chiefs of the units who stayed behind with the wounded Serbian soldiers in Serbia, including the following:

Order of the White Eagle, Fifth Class: Dr. Elsie Inglis.
Order of Saint Sava, Third Class: Dr. A. Hutchison and Dr. Holloway.

Various grades of the latter order are bestowed upon the president, the treasurer, and chairmen of various committees.

Dr. E. Inglis, upon whom the Order of Saint Sava, Third Class, was bestowed during her work in Serbia, is the first woman decorated with the Order of the White Eagle.

The *London Gazette* of April 15th announces the grant of a number of decorations and brevet promotions, all dated January 1st. Among them were the following medical officers:

C.B.—Colonel H. M. Adamson, A.M.S., Lieutenant-Colonel J. F. Donegan, R.A.M.C.

D.S.O.—Captain P. B. Bharucha, I.M.S.

Military Cross.—Captain R. C. Clifford, I.M.S., Captain F. A. Robinson, R.A.M.C., Lieutenant (temporary) F. T. Simpson, R.A.M.C.

Brevet-Colonel.—Lieutenant-Colonel E. Jennings, I.M.S.

Brevet Lieutenant-Colonel.—Major S. Anderson, I.M.S.

The War Office announced on April 15th the grant of 11 D.S.O.'s, 37 Military Crosses, and 138 Distinguished Conduct Medals for gallantry and devotion to duty in the field. Among the recipients are three men of the R.A.M.C.: Sergeant H. Langley, 38th Field Ambulance, and Privates S. Mackenna and S. A. Smith, both of the 37th Field Ambulance.

Ireland.

Owing to the large number of children unvaccinated in the Athy Union, the guardians decided last week to direct the officials to issue summonses against a number of the parents.

The Local Government Board have, after a long correspondence, yielded to the wishes of the Swinford Board of Guardians and sanctioned the temporary appointment of Dr. Sweeney as medical officer of the Charlestown dispensary district.

ROYAL VICTORIA HOSPITAL, BELFAST.

At the annual meeting of this institution, held in the Central Hall of the King Edward Memorial Building of the hospital, the president, Lady Pirrie, occupied the chair, and there was a large attendance. The finances are in a sound condition, although the excess of expenditure over receipts amounted to £2,157, owing to the increased cost of supplies and to the opening of the unused wards and of the Memorial Hall. Mr. R. J. Johnstone, F.R.C.S. Eng., honorary secretary of the medical and surgical staff, proposed the adoption of its report. A number of the full and of the auxiliary staff, he said, were serving in either East or West; the staff, therefore, was short-handed, and he desired to express gratitude to those medical men who had filled to a very large extent the places of those of the staff who were away. During the year 2,404 surgical and 785 medical cases had been admitted and 1,598 operations had been performed. Dr. W. Calwell seconded, and the motion was carried.

Scotland.

THE LATE SIR ALEXANDER SIMPSON.

At the meeting of the managers of the Edinburgh Royal Infirmary on April 10th Dr. MacGillivray, the convener of the medical managers' committee, said that Sir Alexander Simpson's distinguished career, and the worthy manner in which he maintained the reputation of the name of Simpson in the Edinburgh medical school had been expressed in the appreciation presented to the board on his retirement from active work in the infirmary in 1905. It remained for the managers to convey to his family an expression of their sorrow and sympathy with them in the sudden loss they had sustained. Sir Alexander Simpson has by his will left the museum of his uncle, Sir James Y. Simpson, to the University. He gave his own library and his uncle's to the Royal College of Physicians.

England and Wales.

At the annual meeting of the County of London Branch of the British Red Cross Society on April 13th, Mr. Martin Holland, C.B., who was in the chair, said that sixteen V.A.D. hospitals (soon to be increased to twenty-three), with 600 beds, had been established by the branch since November, 1914, and the thanks of the meeting were accorded to the various medical officers who had given their services to the hospitals. Colonel James Cantlie, F.R.C.S., vigorously defended his action in organizing emergency classes for first-aid immediately on the outbreak of the war. He drew a sharp distinction between Red Cross work and hospital work. The place for Red Cross work, he said, was along the lines of communications, and not in the hospitals.

In a leading article published last August we referred to the scheme for the educative convalescence of crippled soldiers, initiated last midsummer in the Princess Louise Military Wards at Chailey. In this Sussex village there is established a centre for the training of crippled children in various handicrafts, and the new idea has been to introduce wounded soldiers into this environment, so that, under the influence of children similarly afflicted, the men may learn more readily to accustom themselves to their privations, and to engage in such tasks as bookbinding, carpentry, and basket work. At a meeting at Carpenters' Hall, London, to further the repetition of the experiment this year, Mrs. G. T. Kimmins showed a large number of lantern slides of the work at Chailey, and Bishop Forrest Browne made an appeal for funds. He said that to equip the schools for this enterprise anything from £2,000 to £4,000 would be needed, but any building put up, after serving its immediate purpose, would remain for the benefit of crippled children, who would receive more intelligent and scientific care than had been the case in the past. Some gratifying donations were announced.

Correspondence.

THE "SOLDIER'S HEART" AND ITS RELATION TO THYROIDISM.

SIR,—In his valuable paper under the above title Sir James Barr deals with a subject of considerable importance—namely, the part played by morbid blood plasma in the causation of functional nervous disorders. His observations suggest that many of the symptoms of the war neuroses, hitherto thought to be immediately due to injury of the nervous system, may be the result rather of the action upon the nervous system of a morbid condition of the blood consequent upon the stress and strain of active warfare.

That the blood can be morbidly affected through the nervous system there can be no doubt, and it is equally certain that a morbid blood plasma is capable of giving rise to wellnigh every known variety of functional nervous disturbance, from the mildest neurasthenia to the most virulent type of insanity. Consider the manifold nervous symptoms which arise from the various toxæmias, such as those due to drugs, defective digestion (in the widest sense), pathogenic bacteria, and metabolic disorders, such as diabetes, nephritis, and malignant jaundice. Consider, again, the profound nervous disturbances which result from abnormalities as regards hormonal activity. Now we know that the hormonal tissues (for example, the thyroid and adrenal glands) are highly susceptible to nervous influence, and I have no doubt that Sir James Barr is correct in attributing many of the phenomena of the war neuroses to disordered activity of these tissues. Certain of the symptoms of Graves's disease (for example, tachycardia, tremor, sweating, extreme nervous agitation) are common among soldiers invalided from the front—a fact which has been commented upon by more than one French physician; but I am not aware that the possibility of these symptoms actually being hormonal in origin has been previously suggested. Sir James Barr's observation on the condition of the thyroid in soldiers suffering from irritable heart is of great interest in this connexion.

We meet with all sorts of anomalous vasomotor and secretory disturbances in soldiers suffering from war neuroses, and it seems highly probable that many of these are the result of disordered hormonal function.—I am, etc.,

London, W., April 16th.

HARRY CAMPBELL.

SIR,—The paper of Sir James Barr is very interesting and useful; but without the fact that thyroidism itself is due to a toxic cause or to some deficiency in diet, hardly appears to cover the whole ground.

For instance, whilst a civil surgeon in the South African war, I was aware that men were occasionally in the habit of chewing cordite, with the idea of getting a rest in hospital owing to weak cardiac action. Lately I saw a pronounced case of irregular heart action due—according to the man's own opinion—to his being an habitual taker of small doses of cocaine. I have seen two similar cases due to the action of veronal taken in large doses. Tobacco is admittedly a common cause. Tea is also a cause, which any practitioner who has treated charwomen and washerwomen in faints will probably have guessed. In scurvy and beri-beri heart failure is the usual cause of a fatal ending; and in my opinion a good deal of the excessive mortality amongst artificially fed children is due to a minor degree of scurvy causing the heart and nervous systems to be unable to withstand the strain of minor infantile ailments.

Now soldiers are exposed to nitrite fumes, they smoke too much, their diet consists for long periods principally of preserved meat, white bread, and biscuits, and tea taken from early morning until late at night, owing to water, unboiled, being taboo.

I have used calcium for many years, probably because I was formerly house-physician to Sir James Barr, and can witness to its efficacy. The breakfast tea should be discontinued, as well as smoking before lunch, and all inhaling particularly. Brown bread and oatmeal porridge with fruit and vegetables materially assist.—I am, etc.,

Wallasey, April 16th.

F. WILLIAM INMAN, M.B.

THE HORRORS OF WITTENBERG CAMP.

SIR,—The horrible and ghastly tale of the inhuman conduct of Dr. Aschenbach, the medical officer in charge of the Wittenberg prisoners of war camp, as reported by the Government Committee on the treatment by the enemy of British prisoners of war, is only one more illustration of the infamous effects of German Kultur.

I doubt if the medical profession of any country in the world could produce such a specimen of depravity as this inhuman beast, to whom the Kaiser has presented that, to our minds, symbol of infamy, the Iron Cross, as a reward for the perpetration of systematized murder on a colossal scale.

It is time, Sir, that the medical profession in this country raised its voice in abhorrence and in condemnation of the conduct of a confrère who, trusted with the care of suffering and defenceless prisoners of war, so betrays his trust as to be capable of such cowardly and devilish barbarity as this traitor to our profession.

Man's inhumanity to man
Makes countless thousands mourn.

To mark the feelings of indignation and disgust shared by the medical profession of the British Empire I beg to suggest that the councils of the various sections of the Royal Society of Medicine forthwith delete from their list of honorary or corresponding members the name of any German physician, surgeon, or specialist who may have, in our hour of illusion and delusion, been accorded this honour.

I may say that I have given notice of a resolution on these lines to the secretary of the Laryngological Section and of the Otological Section of the Royal Society of Medicine for discussion at the first possible opportunity.—I am, etc.,

Manchester, April 17th.

WILLIAM MILLIGAN.

PERNICIOUS ANAEMIA AND ERYTHRAEMIA.

SIR,—The treatment of pernicious anaemia by injection of polycythaemic blood, recorded by Dr. O. Leyton in the BRITISH MEDICAL JOURNAL for April 1st, 1916, p. 484, had

also been tried, as Dr. Leyton thought it might have been, some years previously. Walter recorded a case of pernicious anaemia treated by injections of polycythaemic blood in which the effect on the patient's blood state, etc., was satisfactory—that is to say, a very great improvement followed the injections. I do not know whether details as to relapses were published later. I am inclined to think that similar therapeutic trials have been made both in Germany and France. Treatment by normal blood (intramuscular injections, etc.) has, of course, been tried repeatedly.—I am, etc.,

London, W., April 15th.

F. PARKES WEBER.

Obituary.

JOHN KENT SPENDER, M.D.LOND.,

LATE PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH.

DR. J. K. SPENDER, who died on April 14th, was the last of the generation of physicians who laid the foundation of modern Bath as a health resort.

He was the son of the late Mr. J. C. Spender, who practised at 36, Gay Street. Dr. Spender's medical education began there in a little dissecting-room at the bottom of the garden, and he also attended, in 1846, a private institution for diseases of the chest in Chatham Row, Bath, where the late Dr. James Watson, of 13, The Circus, the Nestor of the local profession, taught him the elements of auscultation. On October 1st, 1848, he entered as a student at King's College, London, took the diplomas of M.R.C.S. and L.S.A. in 1852, and later on, in 1868, while in the midst of a busy practice, graduated M.D.Lond. On returning to Bath, he joined his father, on April 21st, 1852, residing at 37, Gay Street. On January 1st of the following year he was elected a member of the local Branch of the British Medical Association, of which he lived to be the oldest member. He had also, we believe, been, although it has not been possible definitely to verify the fact, a member of the Association for a longer period than any other person. He was always an energetic supporter of and regular attendant at the Bath and Bristol meetings. In describing the annual meeting of 1854 he says: "It was held in a small room at the Castle Hotel, and we sat down afterwards to dinner, about 10 all told. The late Dr. Wm. Davies, of 10, Gay Street, presided, and we were a merry lot." It was in consequence of Dr. Spender's efforts that the annual meeting of the Association was held in Bath in the year 1878. The benefit derived by the city as a health resort is very generally recognized. In 1882 Dr. Spender was appointed President of the Branch.

As physician to the Mineral Water Hospital he devoted much time to the institution. His special interest in rheumatoid arthritis is shown in the number of contributions to the press on the origin and etiology of that congeries of diseases. By his knowledge of his subject, clearly expressed in the simplest words, Spender was known to a wide circle. He was one of the earliest investigators to recognize some of the premonitory and initial symptoms of that disease, and his views have been amply ratified by subsequent writers. The "affinities," as he called them, existing between rheumatoid arthritis and Raynaud's disease, such as sweating, were pointed out by him, and also the analogies, such as the rapid pulse, to exophthalmic goitre, a disease, by the way, which was first described by Parry, a Bath physician.

Early in his career Spender made for himself a high position in medical literature, and his contributions were uninterrupted from 1854 to 1894. He never wrote for writing's sake, but there was always something new and something interesting in his articles and in his books. *Therapeutic Means for the Relief of Pain*, which gained for him the Fothergill Gold Medal in 1874, was a masterly summary, which, even in these days of synthetic drugs, is well worthy of study. He himself accounted for his success in literature by the fact that he began to write early in life, and also by his love of English classics. That the gift was largely congenital is shown by the high literary attributes of his family. Acquired attributes are not transmitted to the next generation. A glance round his library showed that Spender's horizon was not bounded

by medicine alone. "Homo sum; humani nihil a me alienum puto"; and his catholicity was seen on his bookshelves—Burke, Landor, De Quincey, Ruskin, and a host of others.

Life was a joy to Spender in the happy family circle with which he was surrounded. Mrs. Spender, the well-known authoress, had congenial ideals. Of his sons, Mr. J. A. Spender is editor of the *Westminster Gazette*, Mr. Harold Spender and Mr. Hugh Spender are well known to literature, as is also his sister Miss Spender.

The death of Mrs. Spender in 1895 was a crushing blow from which Dr. Spender never recovered. Life was no longer life, and he retired from practice. From thence onwards he was an invalid. Devotedly nursed by his daughter, Miss Spender, the evening of life was peaceful.

In reviewing the life of Dr. Spender as a physician, it may be said that his most striking characteristic was the great value he placed upon general principles, while at the same time no detail was too small to receive his attention. Aided by a marvellous memory, every word in speaking or in writing was carefully weighed, and every quotation accurate. As an instance of his observation in small things reference may be made to the spots on the skin in rheumatoid arthritis, which have since been known as "Spender's spots."

In a lecture on the "Automatic Ways of Man," delivered before a local society, he dealt with the subconscious neurological phenomena of daily life so lucidly that an audience of laymen had no difficulty in following him. The lecture was afterwards published, and is an excellent illustration of his literary style.

Probably his last article was published in the *Westminster Gazette* of March 22nd, 1912, with a title reminiscent of Elia, "On the Decay of the Art of Medical Prescribing."

The city for which he did so much will long remember the charm of his personality; his large circle of friends, the courtly grace of his hospitality; and his professional brethren, the scholarly physician and genial colleague.

ARTHUR E. J. BARKER, F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY COLLEGE, LONDON;
TEMPORARY LIEUTENANT-COLONEL, A.M.S.

MR. ARTHUR BARKER, who died on April 8th of pneumonia and nephritis while on active service, was born in Dublin on May 10th, 1850, and was therefore within a month of completing his 66th year. He was the son of Dr. William Barker, and was educated at the Royal College of Surgeons in Ireland and the University of Bonn. He qualified as L.R.C.S.I. in 1870 and L.R.C.P.I. in 1875. He became F.R.C.S.I. in 1876 and was admitted a Fellow of the Royal College of Surgeons of England *ad eundem* in 1880. He was for some time surgeon to the City of Dublin Hospital, and in 1875 he was appointed assistant surgeon to University College Hospital, London, becoming full surgeon in 1885. In 1893 he was appointed professor of surgery in the college. He was also consulting surgeon to the Queen Alexandra Military Hospital, Millbank, and to the Osborne Convalescent Home for Officers. He was Hunterian Professor of Surgery and Pathology at the College of Surgeons in 1889, and had served as Examiner in Surgery at the Victoria University, Manchester, and the London University. He was the author of a *Manual of Surgical Operations* (1887); *Hunterian Lectures on Intracranial Inflammations* (1890); and of articles on diseases of joints in *Treves's System of Surgery* (1895); and *caries of the spine*, etc., in *Holmes's System of Surgery*, vol. ii (1883); and operations on hernia in *Burghard's System of Operative Surgery* (1909). He delivered the Address in Surgery at the annual meeting of the British Medical Association at Belfast in 1909, taking as his subject the progress of intestinal surgery. He had taken an active part in the development of this branch of his art. His attention may have been called to it by the fact that he himself in his early career suffered from a severe attack of what was then known as perityphlitis. In 1886 he recorded in this JOURNAL what he claimed to be the first successful case of gastro-enterostomy for cancer in England. He also contributed many papers to the medical journals on spinal anaesthesia, on the treatment of gangrenous herniae by enterectomy, and other subjects of abdominal surgery, and on the surgery of

joints. In November, 1914, he was appointed temporary lieutenant-colonel in the Royal Army Medical Corps, and served as consulting surgeon to the Southern Command. He found his death in the service of his country at Salonica.

In his early days in London Mr. Barker had to contend with difficulties which might have discouraged a weaker man. But his quiet strength of character bore him up, and as the value of his work came to be recognized he lived down the unpopularity caused by his appointment. He was a lucid and graceful writer and a bold and successful operator. He was a member of the *Deutsche Gesellschaft für Chirurgie*. In 1874 he published a translation of Heinrich Frey's *Histology and Histo-chemistry of Man*, and his knowledge of German, which was a rarer accomplishment at that time than it is nowadays, was useful to him in his professional advancement.

Colonel Barker married, in 1880, Emilie Blanche, daughter of Julius Delmerge, of Rathkeale, county Limerick, by whom he had one son and four daughters.

Medico-Legal.

IMPRISONMENT FOR ILLEGAL OPERATION.

IN the High Court of Justiciary, Edinburgh, on April 14th, a middle-aged woman, named Jane Robertson, or Edward, was charged with having on October 9th and 11th, 1915, performed, in concert with a man unknown, an illegal operation on a young woman, in consequence of which certain complications resulted and she died in the Maternity Hospital, Glasgow, on November 13th. After evidence had been heard, the jury, by a majority, found the accused guilty, and the Lord Justice-General passed sentence of three years' penal servitude.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

A COMITIA was held on April 17th, Dr. Frederick Taylor, the President, being in the chair.

The President announced that he had nominated the following Fellows to serve on the Committee of the Royal College of Physicians of London and the Royal College of Surgeons of England for the consideration of matters referred to it by the Central Tribunal and other duly authorized bodies: The President, Dr. W. Pasteur, Dr. Sidney H. C. Martin, and Dr. J. Galloway.

President's Address.—The President delivered the usual annual address, in the course of which he referred to the honour conferred on Fellows, Members, and Licentiates during the year, including those received in connexion with war service. He also mentioned the lectures delivered in the College, and the medals, prizes, and scholarships which had been awarded. Reference was also made to the report which had been adopted by the College on the duties of medical practitioners in connexion with criminal abortion. He briefly explained the formation of the Central Medical War Committee, of which he had become a member, and also the election of an Advisory Committee in conjunction with the Royal College of Surgeons of England, to advise the Government through the Central Medical War Committee. The President then read obituary notices on ten Fellows who had died during the year: Dr. Henry Lewis Jones, Sir Peter Eade, Dr. David Bridge Lees, Sir Robert Michael Simon, Dr. Robert Maguire, Dr. George Allan Heron, Dr. George Oliver, Sir William Richard Gowers, Dr. Henry Charlton Bastian, and Dr. Thomas Colcott Fox. The President concluded by thanking the College for the courtesy and assistance extended to him by the officers and Fellows. Sir William Church proposed a vote of thanks to the President for his services during the past year, with a request that the address might be printed. This was duly carried, and the President vacated the chair.

Election of President.—The election of President then took place, and Dr. Frederick Taylor was re-elected by a large majority, and expressed his thanks.

Representative on General Medical Council.—Dr. Norman Moore was re-elected the representative of the College on the General Medical Council.

Reports.—A report from the committee of management was received and adopted, recommending that the Leighton Park School, Reading, should be added to the list of institutions recognized by the Examining Board in England for instruction in chemistry, physics, and biology.

The President then dissolved the comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY council was held on April 13th, when Sir Frederic Eve, Vice-President, was in the chair.

Musk Oxen.—A vote of thanks was given to Lady Strathcona for a donation to the museum of two skeletons of musk oxen.

Prizes.—The Jacksonian Prize for 1915 was not awarded. The

subject for this prize for 1917 is "The causation, diagnosis, and treatment of traumatic aneurysm." The Triennial Prize was not awarded. The subject of this prize for 1916-18 is "The development of the hip-joint and of the knee-joint of men." The Walker Prize was awarded to Mr. William Sampson Fandley, for "The improvement in the surgical treatment of mammary carcinoma, due to his pathological investigation." *Election of Members of Twenty Years' Standing to the Fellowship.*—Fleet Surgeon Percy William Bassett-Smith, C.B., and Mr. James Frank Colyer were elected Fellows.

The Services.

EXCHANGE.

LIEUTENANT R.A.M.C., Regt. M.O., desires to change with officer holding a position in base hospital, casualty clearing station, or ambulance train, the latter preferred. Address, No. 1500, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

WE regret to announce the death of Dr. Thomas Colcott Fox, physician to the skin department of Westminster Hospital, which occurred on April 11th at the age of 66. We hope to publish an obituary notice in a subsequent issue of the BRITISH MEDICAL JOURNAL.

THE National League for Physical Education and Improvement has arranged a course of lectures on the care of the school child, for school care committees, teachers, and others, to be held at the London Day Training College, Southampton Row, W.C., on Wednesdays at 5.30 p.m., from May 3rd to July 19th; and also a course of lectures, beginning on May 8th, on infant care, for nurses and midwives, on Mondays at 3 p.m. at the Royal Society of Medicine (1, Wimpole Street), and on Fridays at 8 p.m. at the Coll. of Ambulance (3, Vere Street).

THE report of the King Edward Memorial Sanatorium for Tuberculosis at Bhowali, in the hills of the United Provinces, India, for 1915, shows that 15 patients remained from 1914 and 130 were admitted during 1915. Eight were under treatment less than a month, and 14 were found non-tuberculous. In the remaining 123 tubercle bacilli were found in 80 per cent. The results were: Arrested 30, much improved 35, improved 20, stationary 27, worse 8, died 3. Treatment is on general open-air lines and by the use of tuberculin. The institution was visited by the Viceroy, Lord Hardinge, and by the Lieutenant-Governor of the United Provinces in October.

THE *Southport Visitor* of April 15th contains an interesting account of the work of the St. John Voluntary Aid Detachment Hospital, Southport, which is said to be the largest in England. The illustrations show that the equipment for every detail of hospital work, including amusements for the patients, is very complete. Since it was opened, a little more than a year ago, 366 men have been returned to their fighting units. There have been only four deaths, a proportion of 1 in 200 of cases admitted. All the officers in charge, medical and lay, and all the workers give their services gratuitously, and the inhabitants of Southport have been most liberal in their support. We are informed that 50 per cent. of the proceeds of the advertisements in the issue of our contemporary containing the article is being given to the funds of the local hospitals.

THE monthly meeting of the Central Midwives Board was held on April 13th. Sir Francis Champneys was in the chair. In reply to its inquiry with regard to the opinion of the Central Midwives Board as to the propriety of visits by a health visitor to the house of a lying-in woman, during the period of a midwife's attendance on the case, it was decided to furnish the Local Government Board with copy of correspondence on the subject, which contained a resolution stating the Central Midwives Board's opinion that, "generally speaking, the inspector of midwives is the only person who ought to visit the house of a lying-in patient during the attendance of the midwife, and that any visit paid to a lying-in woman by any other person than the doctor or midwife must be made by the express permission of the patient." On April 14th a penal session was held, when Sir Francis Champneys again presided, and charges against nine women and an interim report were considered. One midwife was censured, one was cautioned, and the other eight were struck off the roll. Most of the women were registered as in practice before the Act, and the charges against them were the usual ones of ignorance and want of cleanliness, but there were also other serious charges, principally that of neglect in cases of ophthalmia neonatorum.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Antology, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

ANSWERS.

PAIN AT ROOT OF NECK AND CARDIAC IRREGULARITY.

DR. ALEXANDER FRANCIS (London, W.) writes: Dr. D. Owen Williams has drawn attention (BRITISH MEDICAL JOURNAL, April 15th) to a symptom which I have found is very common in patients who suffer from the effects of high blood pressure. I have been at a loss to explain the mechanism of the pain, but it disappears on the reduction of the pressure. I have little doubt that high blood pressure was the cause of the trouble in Dr. Williams's patient.

LETTERS, NOTES, ETC.

THE Boylston Medical Prize for 1915 has been awarded to Dr. Wilson G. Smillie of Cambridge, Massachusetts, for an essay entitled *Studies of the Streptococcus of Smith*. The next prize is offered for the best dissertation on the results of original research in medicine; the choice of subject is left to candidates. Dissertations must reach the secretary of the committee, Dr. Harold C. Ernst, Harvard Medical School, Boston, on or before December 31st, 1916. The prize, which is open to public competition, is a sum of £60, with a gold medal.

SMALL-POX IN PERSIA.

DR. JOSEPH SCOTT (Teheran) writes: During some twenty years' practice in the East, where small-pox is always with us, the importance of revaccination has been strikingly brought home to me. The British colony is a small one numbering about 120 persons, yet during the past ten years seven cases have occurred in my practice; three of these were confluent, and all died; the other four made good recoveries. All had been vaccinated in childhood but not since: the average number of marks was two. This is a strikingly high percentage, as it includes children who had been vaccinated and adults who had seen fit to be revaccinated.

OSMOSIS IN THE TREATMENT OF CANCER.

MAJOR C. W. DUGGAN, R.A.M.C., writes: I suggest the following treatment in external carcinoma: After removal of the growth the wound should be left open and painted in the morning and evening with equal parts of ichthyol and glycerine; gauze absorbent wool and a bandage should then be applied. If ichthyol cannot be obtained a dry, non-irritating antiseptic should be substituted. The object of this treatment is to take advantage of the osmotic action of glycerine with a view to preventing a recurrence of the growth and its subsequent diffusion. I also hope that by this method some assistance will have been given to the solution of the cancer problem.

AN ANODYNE POWDER.

LIEUTENANT-COLONEL J. HARDIE NEIL, N.Z.M.C., states that he has found a powder consisting of 5 grains each of veronal, phenacetin, and Dover's powder a very useful combination to combat the pain or distress arising from surgical procedures. After a submucous dissection for instance the patient is given four powders, one to be taken immediately on getting home, a second four hours afterwards, and a third after another four hours if not asleep; the fourth is taken on the succeeding night if the patient does not come up for dressing next day. Usually the patient has a quiet sleep, and awakes in the morning feeling well. In tonsillitis a powder should be taken every four hours, and if relief is not obtained a complication such as peritonsillitis may be assumed. Lieutenant-Colonel Neil thinks that the powder would be useful for quieting patients after injuries received in warfare.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Notes on Military Orthopaedics.

I. REMARKS ON POSITIONS OF ELECTION FOR ANKYLOSIS FOLLOWING GUNSHOT INJURIES OF JOINTS.

BY

LIEUTENANT-COLONEL ROBERT JONES, Ch.M.,
F.R.C.S.I. (Hon.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

THERE are certain injuries to joints occurring after gunshot wounds which must inevitably end in bony ankylosis. From their very nature some of these will not admit of excision.

When a joint has been shattered, and the muscles governing it have been in part or wholly destroyed, excision is not merely difficult from the point of view of surgical technique, but often results in a flail articulation which renders the limb quite useless. This is especially the case when such joints as the shoulder, elbow, and wrist are concerned. Excisions of the upper part of the humerus are frequently practised as a conservative procedure in the presence of acute or persistent sepsis, especially at the French front. This may be very necessary, but the resulting condition will at a later date require further surgical intervention. The question has often been put to me, "What should be done with these flail joints, and, if ankylosis is to be expected, in what position should the joint be placed in order to be of the greatest use to the patient?" The question as to flail joints will be considered at the end of this article, but in the first place it may be of service to indicate briefly the conclusions as to the positions for ankylosis to which experience has led me.

SHOULDER-JOINT.

Position.

The arm should be abducted to about 50 degrees (Figs. 1 and 2). The elbow should be slightly in front of the coronal plane of the body (Fig. 2), so that when it is at right angles and the forearm supinated, the palm of the hand is towards the face. The arm is placed in this position while the scapula retains its normal position of rest.

Reasons.

If the arm be correctly placed the hand (Fig. 3) can be brought easily to the mouth by bending the elbow. Further, the humerus, being fixed to the scapula at the angle indicated, the arm can be lifted to a considerable height by scapular action (Fig. 4); moreover, pockets can be reached, the hair brushed, and the patient can pick up a plate or cup without spilling the contents.

The arm should never be kept to the patient's side if

ankylosis is feared, for in such a case the functional result must be most unsatisfactory; not only will it be difficult to reach many parts of the body, but difficult also to reach across a table or to perform many simple movements constantly recurring in everyday life. Flail shoulder-joints also should be ankylosed in the position described, and joints which have been allowed to ankylose in an adducted position (Figs. 5A, 5B) may require osteotomy of the humerus high up to correct this faulty position. The shoulder-joint should never be allowed to become fixed at right angles to the side in adults, as in that case the patient will be unable to bring his arm down to his side.

It is to be clearly understood that I am dealing with injuries to soldiers and sailors, and not with children in whom other means can be adopted owing to anatomical considerations.

ELBOW-JOINT.

Position.

The proper course to adopt will depend upon the patient and his calling, but by far the greater number of men would prefer the fixation to be at just below a right angle—that is, about 100 degrees (Fig. 6). It is important to bear in mind that in cases in which *both* elbows will become ankylosed it is necessary to fix the one at an angle of 80 degrees and the other at 100 degrees as recommended for one-sided trouble (Fig. 7). The ankylosis commonly met with at 130 degrees is not useful.

Reasons.

This position enables the patient to move his hand to his mouth, button his clothes, brush his hair and to reach over a table. At an angle less than a right angle it is certainly more easy to get the hand to

the mouth and to various parts of the head, but limitations in other directions more than counterbalance these advantages.

FOREARM.

Position.

If the movements of pronation and supination are lost, the radius should be fixed midway between pronation and supination.

Reasons.

The hand is more useful for dressing and eating and for manual labour in this position. A minor advantage is that of appearance.

WRIST-JOINT.

Position.

All injuries of the wrist-joint should be treated with the wrist dorsiflexed (Fig. 8).

This is a priceless surgical axiom, the neglect of which is grave.

It is an urgent necessity where ankylosis is

expected, or where even limitation in movement is likely to occur.

The common deformity of palmar flexion occurs when no splint is applied, or from the use of a straight splint; in all cases in which the arm and fingers are kept on such

a splint palmar flexion of the wrist occurs, and this condition is a lifelong handicap to the usefulness of the hand.

Reasons.

The grip of the fingers is diminished if the wrist is palmar-flexed. The strong flexors overpower the extensors

FIG. 5A.

FIG. 5B.

FIG. 5A shows faulty adducted position of arm, and Fig. 5B the consequent extremely limited power of abduction.

of the fingers, and in consequence proper co-ordination of the finger movements is impaired. The grasp of the hand is strongest when the wrist is in the dorsiflexed position, the balance between the flexors and extensors is better preserved, and the co-ordinated movement of the fingers is secured.

FIG. 8.—Dorsiflexion of the wrist.

The splints required are simple.

In proof of the importance I attach to the dorsiflexed ankylosed wrist, I may state that I always restore hyper-extension of the ankylosed joint from the position of

FIG. 6.—Ankylosis of elbow-joint at 100 degrees.

FIG. 7.—Right elbow at 80 degrees, left elbow at 100 degrees.

flexion by manipulation or incision. This invariably improves the grip of the fingers.

Apart from the impairment of function, a flexed wrist is unsightly.

HIP-JOINT.

Position.

Ankylosis should be encouraged in a position of very slight abduction, with thigh extended and very slight outward rotation (Fig. 9).

Reasons.

The common deformity in ankylosis of the hip is flexion, adduction and internal rotation (Fig. 10), which is the characteristic position we find in an untreated or imperfectly treated tuberculous hip-joint; it leads to lumbar lordosis and an ugly limp. Adduction deformity brings the limb too near the middle line, interferes with the normal position of the sound limb in walking, and by involving abduction of the sound limb, interferes also with a free gait.

If the hip-joint is ankylosed in the fully extended position lordosis and the consequent trouble from back-ache is avoided, and there is freer pelvic movement in walking if the thigh is slightly abducted.

The limb should be very slightly rotated outwards, to avoid the unsightly lift of the pelvis as the patient rises on his toes when walking, due to the immobile condition of

FIG. 9.

FIG. 10.

FIGS. 9 and 10.—Ankylosis of hip. (9) Correct position, in slight abduction with extended thigh and slight outward rotation. (10) Faulty position of ankylosis in flexion with adduction and internal rotation.

the hip-joint. This gives an easier walk than if the toes are pointed straight forward.

KNEE.

Position.

This joint should be fixed in an extended position.

Reasons.

Very good reasons may be given in favour of slight flexion from the point of view of elegance in repose and that of ease in mounting stairs. Due weight should be given to these arguments, but in the case of war injuries the straight position obviates many risks. Ankylosis, as we know, is not necessarily bony; when it is fibrous the tendency is for the flexion angle to increase by exercise. The incidence of the body weight on a slightly bent knee, unless the ankylosis is sound and bony, will increase the flexion. The position, therefore, is mechanically a weak one for carrying body weight. Even when new bone is forming its complete consolidation is sometimes a slow process, and if the surgeon places such a knee in a slightly flexed position the degree of ultimate flexion is often much greater than he would wish. The advantage of increased strength and stability ensured by an extended joint will generally outweigh all other considerations.

ANKLE.

Position.

The foot should be kept at a right angle with the leg, so that the sole impinges on the ground in a slightly varus rather than a valgus position (Fig. 11).

Reasons.

If the reader will recall the ankylosed ankles he has seen, he will remember that most of them were in a valgoid position. A varoid position conduces to a strong type of foot; a valgoid (flat-foot) to a weak foot, and all the disability associated with erroneous deflection of body weight.

FIG. 11.—Ankylosis of ankle with foot at right angle and sole in slightly varus position.

JOINTS OF THE TARSUS AND METATARSUS.

In gunshot wounds and other injuries of the tarsus and metatarsus, the deformities to be feared correspond to the

common static deformity of flat or pronated foot—a subject with which I propose to deal more at length in a subsequent article—that is to say, to pronation at the mid-tarsal joint, flattening of the longitudinal arch, and sometimes flattening of the transverse arch associated with pain in the metatarso-phalangeal joints. Callus exudation added to plantar malposition results in a very crippled foot. In all gunshot injuries of tarsus and metatarsus the surgeon should take care during the later stages of healing not to bandage the sole rigidly against a flat foot-piece, for if that be done every irregularity of bone will conduce to

FIG. 12.—Boot with bar behind heel to relieve injured metatarsal joints and phalanges from pressure.

FIG. 13.—Heel elongated and raised $\frac{1}{2}$ in. on inner border, with small piece on inner side of sole.

callosity when walking is resumed. It is necessary, therefore, at this stage to adjust a splint having an inside arch padded to conform to the natural shape of the foot. Eversion of the foot should be guarded against, and the hollow of the arch should, when possible, be emphasized. Later, the heel of the boot should be raised on the inner side to obviate eversion, and, if the metatarsals are involved, in order to allow of early walking, a bar should be placed across the sole of the boot behind the tread (Figs. 12, 13). Light duty can then be undertaken at a much earlier date.

FLAIL JOINTS.

In answer to the question "What should be done with flail joints?" I would say, "Secure by operation an ankylosis in the most useful position." The only exception is in the case of the hip-joint where by means of simple mechanism a very useful limb may be obtained in spite of the joint being flail.

Preliminary Note

ON

A METHOD FOR THE PREPARATION OF A NON-TOXIC DYSENTERY VACCINE.

BY

H. R. DEAN, M.D., F.R.C.P.,

AND

R. S. ADAMSON, M.A., B.Sc.

(From the Pathological Laboratory of the University of Manchester.)
(Report to the Medical Research Committee.)

THE susceptibility of the rabbit to *B. dysenteriae* (Shiga) is well known, and constitutes a practical difficulty in the preparation of agglutinating serums for use in the recognition of this micro-organism. During attempts to produce antiserum we ascertained that the intravenous injection of one-twentieth of a loop* of the culture of the particular strain which we were using, killed by heating for one hour at 58° C., invariably produced the death of a rabbit in five to seven days. Smaller quantities frequently produced a

fatal result. One strain of Shiga's bacillus was used in all our experiments.

The very marked success obtained by Lorrain Smith, Ritchie, and others by the employment of eusol¹ in the treatment of toxæmia and septicæmia suggested the possibility of its employment *in vitro* for the destruction of the toxins of the bacillary emulsion. The object of our experiments has been to modify the toxic properties of a bacillary emulsion of the Shiga bacillus without interfering with its capacity for producing immunity.

That bacillary antigens are not destroyed by hypochlorous acid has been shown by the successful use of antiformin extracts in the complement fixation reaction by Altmann and Schultz.² In 1912 Dean³ prepared a soluble typhoid antigen by precipitating an antiformin extract of typhoid bacilli with alcohol. By this method a fine white powder was prepared, which was freely soluble in water. The solution so obtained was injected into a rabbit, and induced the formation of agglutinins against *B. typhosus*.

The results of our experiments on forty-seven rabbits have convinced us that it is possible by the use of dilute solutions of hypochlorous acid to prepare a Shiga vaccine, the injection of which is practically harmless to the rabbit, but is nevertheless followed by the production of a satisfactory degree of immunity.

The first few experiments showed that eusol very effectively destroys the Shiga toxin *in vitro*. The entire growth from three agar plates, which had been profusely inoculated with the Shiga bacillus on the day before, was emulsified in 15 c.cm. of saline solution. To the emulsion was added an equal quantity of eusol, and the mixture was allowed to stand at room temperature for twenty-four hours. Of this mixture quantities containing $\frac{1}{10}$, $\frac{1}{20}$, and $\frac{1}{100}$ of the entire growth on an agar plate were injected into the ear veins of three rabbits. No symptoms of any kind were observed, and all these rabbits remained in excellent health during the next seven days, when they received further inoculations. On the seventh day a sample of blood was taken, and agglutination tests were carried out. No formation of agglutinins could be demonstrated.

What is the smallest quantity of eusol which, when allowed to act on an emulsion of Shiga bacilli, will render the mixture non-toxic for rabbits?

In the endeavour to supply the answer to this question we have carried out experiments on twenty-four rabbits. The method employed throughout the series was the same. An emulsion was prepared by rubbing up one or more loops of a twenty-four hours' agar culture in a measured volume of saline. In the later experiments of the series the bacilli were killed by heating the emulsion for one hour at 58° C. In the earlier experiments we relied on the bactericidal action of the eusol. The emulsion was mixed with an equal volume of diluted eusol and left for twenty-four hours at room temperature. The amount of the mixture that was injected was usually 1 c.cm. If, for example, it was decided to inject one-fifth of a loop of culture in a 1 in 1,000 solution of eusol, an emulsion of bacilli was prepared which contained two-fifths of a loop in 1 c.cm., and added to an equal volume of 1 in 500 eusol. The following examples are fairly typical of the results obtained:

Rabbit 27.

This animal was one of the three mentioned above. It had been inoculated on February 26th with one-hundredth part of the entire growth of an agar plate previously digested with an equal volume of eusol. On March 6th it was given an intravenous injection of Shiga emulsion, half a loop, in eusol, 1 in 1,000. (The mixture was shown to be sterile.) The animal remained perfectly well, and on March 10th Shiga emulsion, half a loop, in eusol, 1 in 1,000, was injected. This mixture was found to contain living bacilli, for a few colonies of *B. dysenteriae* developed on an agar slope which had been inoculated with several loops of the mixture. We had been using throughout the experiment the same solution of eusol which had been prepared on February 25th. It will be seen that a 1 in 1,000 dilution of this solution sterilized the emulsion on March 6th, but was unable to do so completely four days later. This result was probably due to the deterioration of the eusol solution. If we had titrated our eusol solution before use and determined the hypochlorous acid content, we should probably have obtained more constant results. The result was, however, of interest, for the rabbit survived the inoculation with the living organism, and had evidently developed a high degree of immunity as a result of its previous inoculations with eusol-treated Shiga emulsion. The rabbit, in fact, showed no

* Throughout this series of experiments we have expressed the quantities injected in loops and fractions of a loop. In all experiments we have used the same platinum loop, and cultures of the same strain, previously grown for twenty-four hours at 37° C. If one loopful of the culture is emulsified in 1 c.cm. of saline solution and of this emulsion 1 c.cm. is injected, the amount injected is reckoned as one-fifth of a loop. The method is old-fashioned but provides comparable measurements, provided that the above precautions are adhered to. We have ascertained that one-fifth of a loop in our series of experiments contains from 160 to 180 million bacilli.

signs of illness after this inoculation. On March 17th a sample of its serum agglutinated a Shiga emulsion in a dilution of 1 in 200.

On March 24th the animal was given an intravenous injection of Shiga emulsion, half a loop, previously killed by heat at 58° C., but without the addition of any eusol. This represents at least ten minimal lethal doses, and a normal rabbit would almost certainly have died within forty-eight hours. The animal was quite well until March 27th, when very slight signs of illness were observed. It was quite well on the following day. On April 3rd the agglutination titre of the serum was found to be 1 in 100. Marked complement fixation was observed in a dilution of 1 in 160. On April 10th it was given an intravenous inoculation of two loops of heat-killed Shiga without eusol. No signs of illness developed, and the animal was quite well ten days later.

The emulsion which was injected into rabbit 27 on March 10th, and which was proved to contain living Shiga bacilli, was injected on the same day into three other rabbits, all of which had previously received two inoculations of a mixture of Shiga emulsion and diluted eusol. Two of these animals survived and one died.

Thus, in three cases out of four, rabbits immunized with a mixture of Shiga emulsion and eusol survived the injection of the living micro-organism. The injection of a living culture at so early a stage in the immunization of these animals was unintentional, but afforded evidence of the efficacy of the eusol-treated emulsions for the production of immunity.

We decided, however, to use in subsequent experiments emulsions of dead bacilli, and with this object all the emulsions used in subsequent experiments were heated for one hour at 58° C. before the eusol was added. Cultures were made immediately before the eusol was added, and the emulsions were in every case found to be sterile. The mixture of killed bacillary emulsion and diluted eusol was allowed to stand for twenty-four hours at room temperature.

It is generally held that the pathogenic action of the Shiga bacillus is due to the presence of an endotoxin, and it is certain that heat-killed cultures of this micro-organism are very virulent for rabbits. We decided, therefore, to determine the action of hypochlorous acid on the toxin of dead cultures. As the result of several experiments, we determined that eusol, in a dilution of 1 in 1,000, greatly reduced, if it did not actually destroy, the toxic action of heat-killed emulsions of Shiga bacillus. Our next step was to determine the minimal quantity of eusol which would abolish the toxic action of a given quantity of emulsion of killed bacilli. The result of our experiment is shown in Table I. The dose of Shiga employed was one-fifth of a loop (160,000,000 bacilli), a quantity which could be relied upon to kill a normal rabbit within a few days.

TABLE I.—Minimal Quantity of Eusol to Abolish Toxic Action.

A.

No. of Animal.	Weight in Grams.	Amount of Killed Shiga Culture.	Eusol.	Date of Inoculation.	Result.
43 (control)	2,230	One-fifth loop	0	March 15	Died March 16.
42	2,130	"	1 in 16,000	"	Died March 25.
46	2,060	"	1 in 8,000	"	Died March 16.
44	2,030	"	1 in 4,000	"	Died March 16.
45	2,000	"	1 in 2,000	"	Died March 19.
47	1,900	"	1 in 1,000	"	No sign of illness

B.

51 (control)	2,210	One-fifth loop	0	March 25	Died March 27.
52	2,100	"	1 in 8,000	"	Died March 31.
54	2,100	"	1 in 4,000	"	Died March 27.
55	2,030	"	1 in 2,000	"	Ill on March 29, but recovered. No signs of illness.
53	2,000	"	1 in 1,000	"	No signs of illness.
50	1,750	"	1 in 500	"	No signs of illness.

It appears from the experiment shown in Table I, A, that the toxin of one-fifth of a loop of culture of this Shiga strain was neutralized by the 1 in 1,000, but not by the weaker

dilutions of eusol which were employed. The survivor of the series, rabbit 47, showed no signs of illness and remained in perfect health. On April 4th we tested its immunity by the intravenous injection of two-fifths of a loop of a killed Shiga culture without any eusol. The animal remained perfectly well and had apparently developed a satisfactory immunity as the result of one immunizing dose of Shiga treated with 1 in 1,000 eusol.

The result of a similar experiment is shown in Table I, B. It entirely confirms the result shown in Table I, A. The animal (No. 48), which was inoculated with 1 in 2,000 eusol in this case, survived after a transitory illness which we noted on the second day after inoculation.

On April 10th the immunity of the three survivors was tested by the intravenous injection of one loop of killed culture—a very large dose. The test proved too severe, and all the animals died.

On the Nature of the Immunity Produced by Eusol-treated Emulsions of Shiga Bacilli.

The experiments above quoted and others, of which we have notes, lead to the conclusion that it is quite possible to produce an effective and almost non-toxic vaccine by allowing a weak solution of eusol to act on a heat-killed emulsion of *B. dysenteriae* (Shiga). We have employed both intravenous and subcutaneous methods of injection, and, except in cases where we have intentionally given enormous doses, we have never observed any at all serious results. Intravenous inoculation commonly produces no sign of illness, and subcutaneous injections are followed at the most by a very slight degree of inflammation at the site of the injection. Rabbits after three, two, or exceptionally one inoculation with eusol-treated Shiga emulsion are able to survive the injection of a heated Shiga emulsion which contains many times the lethal dose for a normal unprotected rabbit. We have on many occasions tested the agglutinin content of the serum of the immunized rabbits, and on one occasion the antibody content of several serums was tested by the complement fixation method. The titre of the serum was in no case a high one, and, in the case of many animals, which were subsequently proved to be highly immune, there appeared to have been no production of agglutinins.

The result is not surprising in view of the fact that the agglutination titre of the serum from cases of Shiga dysentery is usually low as compared with the titre of serum from patients suffering from infections produced by typhoid and paratyphoid bacilli. It is more or less difficult to obtain from a rabbit a really powerful anti-Shiga agglutinating serum by any method of immunization. In any case the presence or absence of agglutinins is, from the practical standpoint, of much less importance than the presence of active immunity, as demonstrated by a test injection of a large dose of virulent toxin.

The following experiments illustrate the method of immunization:

Rabbit 34.

On March 6th Shiga $\frac{1}{2}$ loop + eusol 1 in 1,000 subcutaneously.

On March 15th Shiga 1 loop + eusol 1 in 1,000 subcutaneously.

On March 25th Shiga 2 loops + eusol 1 in 500 subcutaneously.

No evidence of immunity could be obtained by agglutination and complement fixation tests.

On April 10th (test injection) two loops of heat-killed Shiga intravenously without eusol. This enormous dose produced no signs of illness, and the animal was alive and well on April 22nd.

Rabbits 39, 40, and 41.

These three animals were immunized as follows:

On March 10th Shiga $\frac{1}{2}$ loop + eusol 1 in 100 subcutaneously.

On March 18th Shiga $\frac{1}{2}$ loop + eusol 1 in 500 subcutaneously.

On March 24th Shiga $\frac{1}{2}$ loop + eusol 1 in 500 intravenously.

On April 4th Shiga $\frac{1}{2}$ loop + eusol 1 in 1,000 intravenously.

The immunity was tested on April 10th by the intravenous injection of one loop of heat-killed Shiga (without eusol) in the case of rabbits 39 and 41. Rabbit 40 was given two loops of Shiga without eusol. No signs of illness developed, and all three animals were quite well on April 22nd.

We are inclined to think that the inoculations induce the formation of an antitoxin, the presence of which we are at present endeavouring to demonstrate in the serums of our immunized animals.

The Action of Hydrogen Peroxide on Emulsions of the Shiga Bacillus.

We do not venture to express an opinion on the nature of the chemical reaction which takes place between the Shiga toxin and the hypochlorous acid. The result is that the bacillary emulsion loses its toxicity but not its capacity for acting as antigen. It is, of course, easy to say that toxin is converted into toxoid. But this is only another way of saying the same thing, and brings us no nearer to an explanation of what has happened. It is commonly believed that the poisonous properties of toxins are reduced by oxidation, and the possibility that hypochlorous acid destroyed the Shiga toxin by oxidation occurred to us. We have, in consequence, carried out a similar but limited series of experiments with hydrogen peroxide.

Rabbit 37.

An emulsion of Shiga bacilli containing one loop of culture in 1 c.cm. was mixed without preliminary heating with an equal volume of a 1 in 50 dilution of hydrogen peroxide in saline solution. After twenty-four hours 1 c.cm. of the mixture was injected subcutaneously. Cultures made from this mixture showed that it contained a few living Shiga bacilli. The animal died five days later.

Rabbit 36.

An emulsion of Shiga bacilli, containing one loop of culture in 1 c.cm., was mixed without preliminary heating with an equal volume of a 1 in 5 dilution of hydrogen peroxide in normal saline solution. The mixture was allowed to stand for twenty-four hours, and then proved to be sterile; 1 c.cm. of the mixture was injected beneath the skin of a rabbit on March 6th. On March 13th a sample of serum was obtained and produced slight agglutination of a Shiga emulsion in a dilution of 1 in 25. On March 15th another subcutaneous injection was given (Shiga emulsion 1 loop, hydrogen peroxide 1 in 10). The Shiga emulsion had been previously killed by heat, and was subsequently allowed to digest with the diluted hydrogen peroxide. On March 24th a Shiga emulsion was agglutinated by the serum in a dilution of 1 in 50. On March 25th two loops of Shiga emulsion (previously killed at 58° C.) in 1 in 10 hydrogen peroxide solution were injected subcutaneously. The immunity of this animal was subsequently tested by the intravenous injection of two loops of killed Shiga emulsion. No signs of illness were noticed and the animal remained perfectly well.

Rabbit 38.

An emulsion containing one loop of Shiga culture (not killed by heat) was mixed with an equal quantity of undiluted hydrogen peroxide. After standing for twenty-four hours the mixture proved to be sterile, and 1 c.cm. was injected subcutaneously. In this case the concentrated hydrogen peroxide probably destroyed not only the toxic but also the antigenic properties of the emulsion, for the second inoculation of one loop of heat-killed culture in 1 in 10 peroxide proved fatal after five days.

Rabbit 55.

This animal was immunized by the subcutaneous inoculation of one-fifth of a loop of killed Shiga emulsion in 1 in 10 peroxide and later by a second dose of Shiga emulsion, half a loop in 1 in 10 peroxide. The immunity of this animal was tested by the intravenous injection of one loop of killed Shiga culture. No signs of illness were noticed and the animal remained perfectly well.

The results obtained in this limited series indicate that hydrogen peroxide yields results of a similar character to those obtained by the employment of eusol.

Experiments on Man.

The results obtained from rabbits encouraged the hope that a harmless and effective prophylactic Shiga vaccine might be prepared on similar lines.

The vaccine was prepared by digesting a killed bacillary emulsion of double the required strength with an equal volume of eusol (diluted 1 in 250 or 1 in 500) for twenty-four hours at room temperature. The injections were subcutaneous. Up to the present time three persons have been inoculated.

CASE I.

H. R. D. March 11th injected one-eighth of a loop killed Shiga in 1 in 1,000 eusol. Slight redness of skin developed around site of puncture after twenty-four hours. After forty-eight hours a circumscribed swelling developed in the subcutaneous tissue. The skin over the swelling became red, and firm pressure was slightly painful. The swelling increased slightly up to the sixth day, then became smaller and disappeared about the tenth day. It was never very tender and the discomfort produced was trivial; there were no constitutional symptoms.

The second dose, given on March 25th, consisted of half a loop of Shiga in 1 in 500 eusol; the local reaction was slightly more severe. On April 10th one-fifth of a loop (160 million

bacilli) of killed culture without eusol was injected as a test of immunity. The local reaction was so slight that it could only be detected with difficulty.

CASE II.

R. S. A. On March 15th one-eighth of a loop killed Shiga in 1 in 1,000 eusol was injected, and on March 30th one-fourth of a loop killed Shiga in 1 in 500 eusol. There was no constitutional disturbance, and the local reactions were similar to those described in the first case.

CASE III.

R. W. On March 16th one-eighth of a loop killed Shiga in eusol 1 in 1,000 was injected, and on March 30th half a loop killed Shiga in eusol 1 in 500. The local reaction after the first dose was a trifle more marked than in the other cases. The local reaction produced by the second dose was hardly appreciable. On April 10th one-fifth of a loop (160 million bacilli) of killed culture without eusol was injected. There was practically no local reaction.

In all three cases constitutional symptoms were entirely absent. The local reaction was a little more marked than that which follows an injection of typhoid vaccine in an average case. It was usually well marked at the end of the second day, and reached its maximum on the fifth or sixth day. It caused none of us any appreciable inconvenience. Up to the present time we have not been able to demonstrate the presence of agglutinins in our serums.

SUMMARY AND CONCLUSIONS.

Our experiments up to this time show that:

1. The toxicity of an emulsion of *B. dysenteriae* (Shiga) can be enormously reduced, or even entirely destroyed, by the action of a dilute solution of eusol or of hydrogen peroxide.
2. The injection of such an emulsion in which the toxin has been destroyed is followed by the production of a satisfactory degree of immunity.

These results appear to us of sufficient interest to justify the publication of a preliminary note, but we are aware that there are several points which require further investigation.

The original object of these experiments was to diminish or destroy the toxicity of a Shiga emulsion without interfering with its immunizing properties.

The results have been obtained by rather rough methods. In subsequent experiments we propose to use mixtures of counted bacillary emulsions with solutions of eusol in which the content of hypochlorous acid has been determined by titration. It may then be found possible to determine the time which the reaction requires at any given temperature. It will also be of interest to us to ascertain if it is possible to produce agglutinins against typhoid and paratyphoid bacilli by similar methods. It is possible that the method may be found useful in reducing the symptoms which follow the injection of *B. typhosus* and *B. pestis* vaccines.

With regard to the production of a suitable Shiga vaccine we suggest the following procedure:

Prepare an emulsion containing 200 million bacilli per cubic centimetre. Heat for an hour at 58° or 60° C. Mix with an equal quantity of a 1 in 500 solution of freshly prepared eusol in normal saline. Allow mixture to stand at room temperature for twenty-four hours. Inject subcutaneously 1 c.cm. of this mixture; 1 c.cm. will contain 100 million bacilli in a 1 in 1,000 dilution of eusol. The second dose might be given ten days later. Prepare an emulsion containing 800 million in 1 c.cm. Heat for one hour at 58° or 60° C. Mix with an equal quantity of 1 in 500 eusol. Allow to stand for twenty-four hours at room temperature and inject 1 c.cm. A third dose of 200 million or more bacilli, sterilized with heat but without the addition of eusol, may possibly be necessary to complete the production of a satisfactory immunity.

The above suggestions are put forward tentatively as the result of a very limited number of experiments on man. It is quite likely that the dose might be considerably increased as the result of further experience. It is also possible that it may be found feasible to increase the relative amount of eusol in the mixture without diminishing its immunizing properties. Such an increase would be accompanied, in all probability, by a still further reduction in the local reaction.

Of the nature of the action of the eusol on the Shiga toxin we are not in a position to offer an opinion. The

fact that hydrogen peroxide appears to exert a similar action to ensol suggests that the reaction is of the nature of an oxidation process.

THE THERAPEUTIC AND REACTION EFFECTS OF KHARSIVAN.

A RECORD OF 600 INJECTIONS.

BY

H. C. LUCEY, M.D., B.S.LOND.,

TEMPORARY CAPTAIN, R.A.M.C., ROYAL HERBERT HOSPITAL, WOOLWICH.

When kharsivan, the British preparation of the same chemical constitution as salvarsan, was introduced last year, the Medical Research Committee made an appeal to members of the medical profession to furnish it with accurate records of the results, both as regards its therapeutic efficacy and the occurrence of any special incidental symptoms.

For such records, in the treatment of syphilis, to be value, it is necessary that (1) some definite scheme for recording results should be adopted, (2) all disturbing factors, such as errors in technique, should be eliminated.

A scheme such as that shown in the next column will be found useful.

It is convenient to keep a ledger embodying some such scheme as this, the details of which should be filled in every time a patient receives an injection.

In this way, besides noting the immediate reaction to a dose given on a particular date, a permanent record is kept of the patient's syphilitic history. The third case in the reaction scheme may be taken as an example. In the column "Previous Treatment" it will be seen that the patient had an injection of kharsivan 0.6 gram on January 19th, with two mercurial injections to follow. On referring to the page in the ledger recording injections given on January 19th, details of his condition and reaction on that date will be noted, and it will be observed what progress he has made in the interval.

At the present time, as a routine for primary and secondary syphilis, I give three injections of kharsivan 0.6 gram at fortnightly intervals, with two weekly injections of mercurial cream in the intervals. This is a short intensive course, designed to render a soldier fit for active service as quickly as is possible consistent with a reasonable chance of a permanent cure.

That this course of treatment does give him a reasonable chance is shown by Gibbard and Harrison's statistics produced at the International Congress of Medicine, 1913. On a precisely similar course, but using the German preparation "606," they found that only 3.9 per cent. of cases relapsed clinically and 19.4 per cent. serologically within a year of the suspension of treatment. It is, of course, not possible during war time to carry out systematic Wassermann tests or to examine patients at stated intervals for signs of relapse; but up to the present I have had only one man return to me, and that not for a relapse, but for a fresh infection.

I give this case with reserve as an example of re-infection with syphilis, because, unfortunately, the diagnosis of primary syphilis in the first instance, though supported on clinical grounds, was not established beyond all doubt by the finding of *Treponema pallidum*. No examination of the exudate from the sore was made on the first occasion.

D. A. was admitted into hospital on August 12th, 1915, with a sore on the glans penis. This was typical of a syphilitic chancre in this situation, being of the papulo-erosive type,

Hg - Injection of mercurial cream.

circular, and evenly circumscribed, denuded only of epithelium and possessing a glazed surface. There was no pus. The patient had exposed himself to infection three to four weeks previous to its appearance. The incubation period, therefore, favoured a diagnosis of syphilis rather than soft sore.

The inguinal glands on both sides were discrete and enlarged, but they showed no signs of active inflammation. The nature of the glandular enlargement was, therefore, in favour of syphilis. On these grounds the case was diagnosed as primary syphilis, and an examination of the exudate for *Treponema pallidum* was not considered necessary. He received the 1.2.1.2.1 course of treatment, as indicated above. The sore rapidly healed and the inguinal glands were reduced.

On January 24th, 1916, he was readmitted with a fresh sore. This was in the coronal sulcus, and well away from the site of the previous sore, so that this could not be a case of "redux chancre." The sore was a typical Hunterian chancre. He had exposed himself to infection four weeks previous to its appearance, and the inguinal glands on both sides were enlarged. There were no secondary signs. This time the exudate was examined for *Treponema pallidum*, which was found to be present. The evidence therefore, though not complete, is in favour of this being a case of reinfection with syphilis, the previous infection having been completely cured by a course of treatment consisting of three injections of kharsivan (0.6 gram) and four of mercurial cream.

I confess, in peace time, I would prefer to give a longer course than this, especially for secondary cases, but my object in this paper is not so much to discuss the merits of any particular course of treatment, but rather to state my experience of the immediate therapeutic and reactionary effects of kharsivan.

The Immediate Therapeutic Effect of Kharsivan.

I believe kharsivan to be every bit as potent as the original German preparation. It may be objected that by adding mercurial injections to the course of treatment the effect of the drug cannot be properly determined. But the immediate effect of kharsivan given without the addition of mercury is apparently as rapid as when mercurial injections are added. The type of lesion which clears up most rapidly is, as would be expected, one in which the blood supply is good, and in which there is no breach of surface. This is particularly well marked in those cases of syphilitic infiltration met with in the later stage of syphilis, around the mouth and nose, causing great disfigurement. A patient suffering from such a lesion looks a different person a few days after a single injection.

Primary sores are rendered inactive after one injection; the time taken, however, before they become completely healed varies according to the extent of breach of surface, the degree of added infection, and the situation of the sore. Those situated on the skin as a rule take rather longer to heal than those on mucous membrane. I find the average time for all primary sores to be fifteen days, using in addition to the general treatment some local application such as lotio nigra or calomel.

The activity of a rash is immediately checked after the first injection, and it disappears in a few days or weeks according as to whether it is a roseolar or a pigmented papular rash. A very deeply pigmented rash may take months to fade completely. Condylomata and mucous patches usually clear up within a week.

Enlarged lymphatic glands are reduced at the end of a course of treatment, though, as a rule, if this has lasted only a few weeks, not sufficient time has been allowed for their complete subsidence. This is only what one would expect owing to their solid consistence. They subside completely later. That incomplete reduction of the lymphatic glands, at the end of a short intensive course of treatment, does not signify incomplete destruction of the *Treponema pallidum*, is shown by the absence of relapses in the great majority of such cases. Experimental evidence is afforded by Iversen,¹ who punctured the glands in 10 cases of secondary syphilis before and after an injection of salvarsan. He found that, whereas before the injection the organisms were present in large numbers, they could not be detected three to five days after an injection.

Reactions following Injections of Kharsivan.

I am in the habit of injecting six to a dozen cases in one morning. It is useful to do them in groups like this, because each case serves to control the others. Thus the technique, dosage, and batch of kharsivan being the same for all, if only one or two cases show a marked reaction of the usual febrile type, it is only reasonable to look for the cause in the individual rather than the solution injected.

If all, contrary to the rule, show marked reactions, then it is only reasonable to suppose that some common disturbing factor has been introduced—for example, bacterial contamination of the saline. Similarly one is able to test one batch of kharsivan against another.

Saline fever can be ruled out of this series, as freshly distilled water has been used throughout.

Except in a few cases where it has been thought safer to go gently, the full dose (0.6 gram) dissolved in 200 c.cm. of saline, has always been given, and in no case has one full dose followed another at a shorter interval than fourteen days.

No breakfast is allowed previous to the injection, and bed for twenty-four hours and no food for six hours after the injection has been the rule.

The absence of any unpleasant symptoms in the great majority of cases is very striking; 72 per cent. of the injections were followed by no symptoms whatever. The figures given below, relating to the various reactionary symptoms, must not be taken to indicate the number of patients who react, but only the frequency of the symptoms, a combination of which may occur after a single injection in one individual.

Pyrexia—The two chief factors (the saline being pure) which determine whether or no an injection will be followed by a rise of temperature to 100° F. or more are: (1) The absence of previous treatment; (2) the stage of syphilitic infection.

To catch a rise it is necessary to take the temperature four and eight hours after the injection. It is often not marked until after the first four hours. There are two types of cases in which after the first injection a reaction of the usual febrile type can be predicted.

(1) A previously untreated case of primary syphilis which is two weeks or more old.

(2) A previously untreated case of early secondary syphilis, particularly when associated with an active primary sore.

In reality these two types represent one stage, that is, generalized infection in the host who is fresh to it, only in (2) this is more advanced and apparent, and is usually marked by a more severe reaction. The temperature in such a case may rise as high as 103.5° F., and this may be associated with any or all of the following symptoms—rigor, headache, vomiting, diarrhoea, and occasionally a Herxheimer reaction. (See Case II in the reaction scheme.) Very often, however, and especially in primary syphilis, the reaction is limited to a temporary pyrexia, and no symptoms whatever are complained of.

It is most unusual for a reaction of this type to take place after a second injection given a fortnight later. It is rare for very early primary, and later secondary, and tertiary cases to show much of a reaction.

It would seem, therefore, that the freshness of the patient to the infection is a factor as well as the degree of infection in determining whether a reaction takes place or not. It is interesting, when injecting a group of men, to pick out beforehand those who are likely to react, and it is surprising how accurate it is possible to be. It must be remembered that a patient who has an acute superadded infection, such as a tonsillitis or influenza, may show a febrile reaction after an injection. As a result of the administration of the drug some of the pyogenic organisms are probably killed off and their toxins set free, hence the sudden rise in temperature.

Douglas and Colebrook² have recently shown that the blood possesses a marked bactericidal power an hour after an injection with neo-salvarsan, but that this diminishes rapidly in a few hours. The bactericidal power was not so marked when salvarsan was used.

Headache occurred in 17 per cent.

Rigor occurred in 5 per cent.

Vomiting, usually only slight but occasionally severe, occurred in 7 per cent.

Diarrhoea occurred in 10 per cent. This varied from two to eight motions in twenty-four hours. It is possible that in a few of these cases the looseness of the bowels was aided by a purgative given on the previous night.

Transient albuminuria developed on the day following the injection in 0.3 per cent. The urine was always tested before and twenty-four hours after. One of the cases gave a history of previous kidney trouble, though no

albumin was present just before the injection. In this case transient albuminuria occurred after each injection.

Herrheimer's reaction occurred in 2.3 per cent. These were all early and previously untreated cases of secondary syphilis, and in most of them the primary sore was still active. The rash became more prominent a few hours after the first injection, and subsided again almost as quickly as it arose.

Herpes labialis occurred in one case. This was an early and previously untreated secondary case, with an active primary sore. As was to be expected, the immediate reaction was severe. The temperature rose to 103.5°, and was accompanied by a rigor, headache, and diarrhoea. He felt quite fit next morning, and the herpes did not appear until forty-eight hours later. Herpes does not occur apart from pyrexia. In the days when impure saline was used its occurrence was far more frequent.

Thrombosis of the vein at the site of injection occurred in 0.5 per cent. In two out of the three cases the needle had frequently to be readjusted, as the fluid flowed in very slowly and at times stopped altogether. It is a question whether this slow rate of flow, in conjunction with the local injury to the vessel wall due to the needle, caused the thrombosis, or whether the thrombosis was due to the irritation of the fluid injected. The former seems the more probable, as one would expect to get a higher percentage of these cases if the latter was the explanation. The amount of sodium hydroxide used in each case was the normal.

Dermatitis occurred in one case only. The rash was of a very mild character; it was limited to the limbs, and required no treatment. It started forty-eight hours after the second injection, and cleared up within a fortnight. It recurred after a third dose—this time a half dose (0.3 gram)—and subsided as before.

A reaction due probably to an abnormal arsenical toxicity in a particular batch occurred in 0.5 per cent. This reaction, which came on towards the end of, or a few minutes after, an intravenous injection, consisted in slight oedema of the lips and eyelids, a sense of fullness in the throat, and epigastric pain. Two patients fainted as they walked to bed. The localized oedema subsided almost as quickly as it arose, but the epigastric pain lasted longer. In addition there might be a rise of temperature, headache, and diarrhoea. In Case A the reaction occurred after an injection with 0.6 gram of batch No. 85. This was the third injection, and it was given twenty-five days after the second. The batch used for the first and second injections was No. 82, the dose in each case being 0.6 gram. These injections were not followed by any such reaction.

In Case B the reaction also occurred after an injection with 0.6 gram of batch No. 85. This was the second injection, given twenty-seven days after the first, when 0.6 gram of batch No. 82 was used with no ill effects. A third injection with 0.6 gram of batch No. 91 was given in this case, fourteen days after the second, with no ill effects.

The occurrence of this reaction on both occasions with batch No. 85 naturally made this batch suspect. I find I have used it forty-eight times, and, besides the two cases mentioned, I find only one case which showed any special symptoms. This man turned pale and fainted as he was walking to his bed. His pulse was soft, but the rate did not rise above 72, and he was well again in a few minutes. He had no oedema or epigastric pain. The injection was his first, and the full dose was given. When an injection gives rise to a reaction out of the ordinary, the question is apt to arise whether or not the addition of the alkali, to the drug in acid solution, was omitted. There is no chance, however, of this error having been committed in any case in this series, as a point has always been made of tabulating in the reaction scheme the amount of alkali required for each dose before injecting it. Some such precaution as this is necessary, as it is a mistake made more easily than might be supposed.

I have gone into detail over these cases, not because they caused any real anxiety, but because they showed a reaction out of the ordinary; a reaction, in fact, which cannot be put down to the stage of infection of the patient or to faulty technique in the administration of the drug. Neither can it be put down to "cumulative action." The reaction was too sudden for this; moreover, the interval

between the successive doses was in the two cases A and B twenty-five and twenty-seven days respectively, and in Case B a subsequent full dose, though from a different batch, was given fourteen days later with no ill effect.

Nor can these patients be said to have shown an idiosyncrasy for arsenic as given them in the usual form of the disodium salt of dioxidiamido-arsenobenzol, as they did not show any toxic symptoms to full doses given with any other batch than batch No. 85.

I believe this reaction to be an indication that the particular batch used contains a rather higher percentage of arsenic in a toxic form than should be the case. The symptoms suggest a toxic action on the vascular endothelium, with effusion of serum in certain localities where the tissues are lax, and a general lowering of blood pressure. In view of the fact that only two, or possibly three, patients out of forty-eight injected with the batch in question—which was one of the earlier ones—showed a toxic reaction, it cannot be said that the increased toxicity in this case was very marked.

It is known that different samples of salvarsan and neo-salvarsan vary slightly in their toxic (organotropic) properties. The total toxicity of these complex arsenical preparations can only be tested by experiments on animals. By this means batches which are found to be distinctly toxic are prevented from reaching the public, but it must happen occasionally, and more particularly when a preparation is first brought out, that a rather doubtful batch is passed, and I think this is a case in point. Certainly I have had no such reaction with any of the later batches, all of which have proved highly satisfactory.

THE HISTORY OF ORGANIC COMPOUNDS OF ARSENIC IN THE TREATMENT OF PROTOZOAN DISEASES.

By BENJAMIN MOORE, D.Sc., F.R.S.

THE man who welds the last link in the chain, especially if he assigns a name to the link, often gains the reputation of having forged the whole chain, and this is especially true in regard to the series of discoveries which have led up to salvarsan and neo-salvarsan.

But the pioneers are the real discoverers, and it appears necessary to make some attempt to keep history correct in this field at the present moment, or the labours of the pioneers may become forgotten. The whole history of the therapeutics of organic compounds of arsenic revolves around the discovery and applications of atoxyl, the first of these compounds to be synthesized and applied in the treatment of protozoan diseases.

Salvarsan and neo-salvarsan are simply derivatives of atoxyl obtained in attempts to suit the original discovery more accurately to treatment.

It is noteworthy that the contributions of the observers of France, Britain, and Germany towards the evolution are just those which might have been expected from experience in the scientific history of these nations.

Atoxyl, the mother substance of the group, was discovered by the famous French chemist A. Béchamp in 1863. Béchamp was the author of a long series of papers on organic chemistry and bio-chemistry, and in 1863, when the properties of aniline and its coloured derivatives were attracting much attention, and shortly after the first of the aniline dyes had been obtained by Perkin, he obtained atoxyl by heating a mixture of aniline and arsenic pentoxide to a temperature of about 190° C. In his original paper Béchamp stated how he had isolated atoxyl, and accurately described its properties and those of its more important salts. By an error easily excusable in a first paper at the date 1863, he described his newly-discovered compound as an anilide of arsenic acid.

The discovery lay dormant for many years until the compound was exploited as a remedy for cutaneous infections by the Berlin firm called the Lanolinfabrik Martinikenfelde. The substance, now labelled atoxyl, was made by Béchamp's process, and misleadingly described as an anilide of arsenious acid. The process of manufacture

was entirely concealed, and the description as a compound of arsenious acid, which is not used at all in the manufacture, was obviously introduced in order to throw chemists off the track. The formula published—namely, $C_6H_5NHAsO_2$ —is entirely erroneous and misleading. The name atoxyl was given because the compound was found to be many times less poisonous than inorganic arsenical compounds.

The substance was first recommended in Germany as a therapeutic agent in skin diseases—an obvious application from the known properties of the inorganic arsenical compounds.

The new remedy, however, entirely failed in this field; it became discredited as a remedy in skin affections, not merely from its failure as such, but because it caused in certain cases optic atrophy and blindness.

If no fresh research had been made at this point atoxyl would have become forgotten, the whole development of organic compounds of arsenic in therapeutics would have been delayed, and there would have been no salvarsan ("606") or neo-salvarsan in our generation.

The first movement, it will thus be seen, arose in France from Béchamp's discovery, the next step came from Britain; it was not made by Koch, as erroneously stated in a recent paper in this JOURNAL. Thereon arose the whole harvest of the later therapy of organo-compounds of arsenic in the treatment of syphilis and other protozoan diseases. This is a point worth emphasizing at a moment when many are lauding German scientists as the discoverers of the remedy for syphilis and related protozoan diseases.

A Canadian observer, H. Wolferstan Thomas, working in the School of Tropical Medicine at Liverpool, found that arsenical compounds had a distinct therapeutic value in the treatment of various diseases due to trypanosomes, and was searching for an arsenical compound less toxic to the host and more fatal to the protozoans. He applied atoxyl, and found that this drug, the first organic arsenical compound to be thus utilized, had a wonderful effect in prolonging life in infection with several different types of trypanosomes.

This paper was published long in advance of Koch's report on the treatment of sleeping sickness, and in it Thomas distinctly advocated the use of atoxyl in human trypanosomiasis.

Therein lay the germ of all future discoveries as to the application of organic arsenical compounds in the therapeutics of protozoan diseases. The future lay in the detailed experimentation as to the best compounds of the organo-arsenical compounds to be used.

Although the origin of atoxyl and its chemical constitution had been concealed, Ehrlich himself at a later period acknowledged its discovery by Béchamp and the priority of the English in its application; thus he writes in *The Experimental Chemotherapy of Spirillooses*, translated by Newbold and Felkin (Rebman, Limited, 1911):

I myself, at the very beginning—January, 1903—of my trypanosome researches, employed atoxyl in conjunction with Dr. Shiga, but abandoned it because it did not exercise any destructive action on the parasites in the test-tube. Therefore directly I became acquainted with the positive result obtained by the English authors, I again took up the study of atoxyl in the summer of 1905, and set myself the task of finding out new preparations which belonged here, and which were of greater curative power and less toxicity.

This somewhat self-protective acknowledgement is all very well at such a late period, but it is to be remembered that nothing regarding the application of organic arsenical preparations of arsenic in trypanosomiasis or other protozoan diseases had appeared in Germany till long after Thomas had published his paper, and that atoxyl, discovered in France, was only exploited in Germany as a secret proprietary drug and described under a most misleading formula. It is again to a French chemist, M. E. Fournéau, that the world owes the merit of having shown that atoxyl was the substance discovered by Béchamp in 1863. He stated this quite clearly in the *Journal de pharmacie et de chimie* in April, 1907, in a passage which may be translated as follows:

According to a circular sent out by the manufacturers of atoxyl "atoxyl is the anilide of meta-arsenic acid; its constitutional formula is $C_6H_5NHAsO_2$, and consequently it contains 37.69 per cent. of arsenic."

The formula assigned to atoxyl by the manufacturers, probably with the object of defeating competition, is false.

Atoxyl is not a new product, but a product which has been known for a long time. It was not discovered by a German, but by Béchamp in 1863; he obtained it by heating arseniate of aniline.

This is established by the analysis of atoxyl, by the examination of its properties, and by a comparison of atoxyl of German origin with ortho-arsenanilide prepared according to Béchamp's method, the two bodies being identical.

It was only some time after this exposure by Fournéau of the identity of Béchamp's original compound with atoxyl that any publication of the real constitution of atoxyl appeared from any German laboratory.

As the use of atoxyl in the treatment of protozoan diseases had been introduced from the Liverpool School of Tropical Medicine, it was natural that the constitution and mode of action of the drug should interest other workers in the school, and in 1906 the present writer, in collaboration with Nierenstein and Todd, commenced work upon the subject.

It was soon discovered that it was not an anilide from its resistance to hydrolysis and general stability to reagents. No modern chemist capable of producing the substance and experimenting on its properties could possibly make such a gross error as to its nature, and one is driven to the view that, like the concealment of the process of manufacture discovered by the French chemist, the formula given and the statement that it was an anilide of arsenious acid, were both meant to deceive and lead away from any use of arsenic acid in the process of synthesis.

The substance is obtained by the simple process of heating molecular proportions of arsenic pentoxide and aniline above the boiling point of aniline and separating from other products in the melt. In their work, Moore, Nierenstein, and Todd showed that:

The substance atoxyl is in all probability not an anilide, but a sodium salt of an organic acid containing an amidogen group and an arsenic radical directly united to a benzene ring.

The only known organic arsenical compounds showing a similar stability to the action of alkalis are those containing the arsenic directly united to the benzene ring—such as phenyl-arsenic acid and its salts ($C_6H_5As(OH)_2$ and $C_6H_5As(OH)(ONa)$).

Its toxic properties are neither those of arsenic nor of aniline, even when pushed to excess, and its therapeutic action is rapid; from this and its high conductivity showing high dissociation the conclusion is drawn that its activity must be ascribed not to free inorganic arsenical ions or to free aniline, but to a complex organic ion containing both the arsenical and aniline radicals.

Before the introduction of atoxyl into the therapy of trypanosomiasis by Thomas a great deal of research had already been expended on the subject by observers all over the world. Ehrlich and his school were at work upon the subject, and had been experimenting with aniline colours, usually with negative results, except in one or two instances. One colour which produced the greatest effect, but still only acted feebly, being named "trypanroth" on account of its action.

As soon as Thomas published his results, Ehrlich and his collaborators set to work, as recorded in Ehrlich's own words earlier in this paper, and, practically simultaneously with the paper from the Liverpool school described above, Ehrlich and Bertheim published a paper showing that atoxyl was para-amido-phenyl-arsenic acid.

From this stage onward to salvarsan and neo-salvarsan the experimental work consisted in experimenting with various derivatives of atoxyl to find those most suitable for therapeutic use.

These are all aniline derivatives, containing, like atoxyl, an arsenical group directly attached to the benzene nucleus, and hence atoxyl may be regarded as the mother substance for them all. Salvarsan was originally obtained by using atoxyl as a starting point and condensing so as to obtain two derived amino molecules united by the arsenical groups.

Neo-salvarsan is obtained by the introduction of a simple side-chain group giving a substance with more favourable solubilities for administration.

This last stage in experimentation requires a battery of working chemists and therapeutists producing a large number of small variants and testing them patiently in a large number of experiments.

The rôle here is exactly that which suits Teutonic talent, and it was here that the combination of the chemical staff of the Höchst Anilinfabrik and the Frankfurt School of Therapy achieved the success which repaid them commercially and gave them the credit of

making a discovery when they had really only succeeded in exploiting at the concluding stages the pioneer work of others.

Soon after the publication of the constitution of atoxyl the writer met Ehrlich in Liverpool on his way to receive a medal at a sanitary congress being held in Douglas, Isle of Man, and congratulated him on his recent paper with Bertheim establishing the constitution of atoxyl, remarking that he had an able and energetic young man in Bertheim. The Geheimrath laughed heartily and said: "Energetic young man! Why he is a director of the Höchst Anilinfabrik, one of the greatest aniline dye works in Germany, and turned the whole staff on to the work."

It is in this combined team work, dealing with minute details, that Germany excels, and the history of the production of organic arsenical therapeutic agents is very similar to that of the aniline dye industry.

SUMMARY.

To conclude this brief sketch of the history of the therapy of protozoan diseases by the use of organic arsenical compounds, a history which only pretends to present the salient points and not to give any complete account of the literature, the following summary may be given:

Atoxyl, the mother substance, was discovered in France, the application to protozoan diseases was made by a Canadian working in a British laboratory, and the chemical nature of atoxyl was shown simultaneously in England and Germany; then German observers finessed amongst the derivatives to find the compounds best adapted for therapeutic use.

The details of production of the compounds were not revealed by Germany, and it is a matter for congratulation that these can now be manufactured in Britain.

THE PREVENTION, SYMPTOMS, AND TREATMENT OF TETRYL DERMATITIS.

BY

ENID SMITH, M.B., B.S.LOND.

For the past nine months I have acted as medical officer to munition works employing about 250 women, where tetryl (tetra-nitro-methyl-anilin) is used.

This note, on the means used to avoid the dermatitis and other troublesome symptoms caused by handling this explosive, is written at the suggestion of Dr. Legge, H.M. Medical Inspector of Factories.

I. SELECTION OF WORKERS.

Experience showed that women with obvious eye or skin diseases should be excluded, and all workers should be taken on probation. It is quite impossible to foresee who will prove susceptible.

II. PROPHYLAXIS.

On entering the factory the workers remove their outdoor clothes, put on special overalls and slippers, and pass through a toilet room, where a responsible person sees that each worker hardens her hands in spirit lotion (filtered methylated spirit 20 per cent., water 80 per cent.) and dusts her face freely with powder (zinc oxide 1, starch 3).

In the rooms the workers are warned against touching their faces with their hands. The trays and tables are regularly wiped and the floors swept and scrubbed, so that the quantity of tetryl is limited. Tetryl-laden dust, or finely divided tetryl seems to be more injurious than tetryl in bulk. Some workers use veils or muslin across the mouth to avoid inhaling the dust. The rooms should be airy and cool, but not draughty. Hot, close weather increases the trouble, so that provision must be made for keeping the rooms cool in summer.

On leaving the works, the workers should wash their hands, using olive-oil soap or bran. Each worker should

have her own towel. The face is wiped free of powder and a simple greasy preparation may be used at the end of the day.

Washing of Clothes.—It should be noted that those living with workers get affected, especially if they wash the workers' clothes. All clothes should be soaked in cold water and paraffin and rinsed before being boiled, or the steam from the boiling clothes will be very irritating.

III. SYMPTOMS.

The hands of all workers are stained yellow, and in most of them the faces and hair. They are known in the town as the "canaries." The conjunctivæ are never stained, nor the covered portions of the body, but the feet may get "yellow as duck's."

Dermatitis, by which almost all workers are attacked, consists, in its mildest form, of irritation and roughening of the exposed skin. More serious is a papular eruption; in the severest cases there is acute oedema of the whole face, closing the eyes and making the features unrecognizable; any variety of eczematous eruption may be seen. The attack may occur at any time, but usually after a fortnight's exposure.

Conjunctivitis may occur with or without dermatitis.

Nasal irritation manifests itself in excessive sneezing and in epistaxis, but is never severe enough to keep a worker at home.

Pharyngeal irritation has occurred in a few cases. Asthmatic attacks compelled two workers to leave.

Constitutional symptoms are almost absent. Insomnia perhaps occurs out of proportion to the cutaneous irritation. "Biliousness" at the monthly periods has been noticed. It has not been found necessary to give the workers rest days on this account. The appetite is excellent, and the general health of some delicate women has certainly improved.

TREATMENT.

If the symptoms are slight the worker is encouraged to remain at work, perhaps changing to a room where tetryl is not used. The symptoms will then, as a rule, subside in the course of a few days and not recur.

If the symptoms are more severe—if, for example, there is oedema or a papular eruption, or conjunctivitis of moderate degree—the worker must stay at home. She should not return until quite well, as a convalescent seems unusually susceptible. If, after recovery, the worker gets a second severe attack, I advise her to find other work. In some cases, however, where the worker has remained at her own risk, she has gradually improved, and the skin, apart from pigmentation, has become practically normal.

For the dermatitis, in the severest cases, steaming the face with subsequent application of wet cloths reduces the swelling and allays the irritation. Later on, and in less severe cases from the first, calamine lotion acts well, though some prefer an ointment composed of zinc ointment, lanoline, and castor oil, equal parts. I have avoided lead lotion, as lead has a dangerous affinity for tetryl.

For conjunctival irritation colloidal silver acts well, though it smartens on application. For nasal irritation we use liquid paraffin.

RELAPSING PARATYPHOID "A" INFECTION.

BY

ALEX. MILLS KENNEDY, M.D.GLASG.,

TEMPORARY LIEUTENANT, R.A.M.C.,

BACTERIOLOGIST TO THE ROYAL HERBERT HOSPITAL, WOOLWICH,
AND

B. R. G. RUSSELL, M.D.ABERD.,

TEMPORARY CAPTAIN, R.A.M.C.

SINCE the outbreak of the war paratyphoid fever has received a considerable amount of attention, and, with the extension of bacteriological laboratories, further opportunity has been afforded for its study. So far as recognized, the cases have presented more or less definite clinical manifestations, and the diagnosis is usually confirmed by the bacteriologist. That the infection may present itself in anomalous or atypical forms seems very probable, yet, so far, there has been little reported on the subject.

The case of paratyphoid A infection herein recorded is one presenting several remarkable and unusually interesting features, and a correct diagnosis might not have been made had we not succeeded in isolating the organism from the patient's own blood.

The patient, aged 32, a private in the New Zealand Force, left Gallipoli about the second week of September, 1915. He stayed for seven days at Malta, and arrived in England in October. At the end of the previous June he had had an attack of diarrhoea lasting seven to ten days only, and not necessitating his being invalided, but, with this exception, he had been quite well until arrival here.

On October 10th, 1915, three days after landing in this country, he was taken ill with shivering, pains in the back and legs, and vomiting, and was admitted to the Royal Herbert Hospital on October 15th. On admission he was found to be febrile, with a temperature over 102° F., pulse 100, and respirations 24. He had headache and some vomiting but no diarrhoea, and there was nothing to be made out in any of the viscera; the spleen was not appreciably enlarged.

The fever persisted for eleven days. For the first five days after admission the evening temperature was always about 103° F., and there were morning remissions to 100° F. and 101° F.; thereafter the morning remissions became more marked and the evening rise tended to get less, so that the temperature curve resembled the defervescence of an ordinary typhoid fever. From the twelfth to the twentieth days after admission the temperature did not quite settle; the morning temperature was usually normal but there was a persistent evening rise to about 100°, and on two occasions it reached 102°.

From the twenty-first day after admission until the morning of the thirtieth day there was practically no fever, the evening temperature never being above 99° and the morning temperature always normal, and the pulse usually ran about 80.

On the evening of the thirty-fifth day of illness (that is, the thirtieth day after admission), the temperature rose to 101.2° F. and reached 103.8° F. the following night, and with occasional slight morning remissions the fever persisted till the forty-seventh day; on the thirty-ninth day the morning temperature was 104° and the evening 105.8°; during the next three days the temperature remained about 104°; on the forty-third day the morning temperature was 103° and the evening 104°; on the forty-fourth day the morning temperature was 101.8° and the evening temperature 103°. With increasing morning remissions the temperature gradually fell to normal on the morning of the forty-eighth day of illness. From the forty-eighth day until the fifty-seventh day of illness the temperature remained practically normal, except on the evenings of the fifty-second and fifty-third days, when it rose suddenly to 102° and 100° respectively.

On the evening of the fifty-eighth day the third relapse was ushered in by a rise of temperature to 102.4°; the following night the temperature reached 104.6°, and remained between 103° and 104° until the sixty-fifth day, when it again showed morning remissions with a gradually falling evening rise. By the seventy-fifth day the evening rise was only to 99.8°, and thereafter both morning and evening temperatures remained normal until the ninety-fifth day. On the evening of the ninety-fifth day a fourth and similar febrile attack was ushered in by the temperature rising to 103°. The following night it rose to 105°, and remained between 104° and 105° for two days longer; then it gradually fell by morning remissions as before until the hundred and eighth day, when the evening rise was only to 99° and the morning temperature 97°. The temperature touched 99° on the two following nights, but remained normal for the rest of the time that the patient was under observation—namely, forty-five days.

Taking the onset of the fever as dating from the onset of symptoms (shivering, etc.), we see that there was an attack of pyrexia lasting about sixteen days; this was followed by a period of eight days in which, although the morning temperature was normal, there was an evening rise to about 100°. An apyrexial interval of ten days followed, and this was succeeded by a second pyrexial attack lasting about fourteen days. Thereafter an apyrexial interval of nine days ensued, to be succeeded in turn by a third pyrexial attack lasting sixteen to seventeen days. A period of apyrexia lasting twenty days followed, and this was succeeded by the fourth and last period of pyrexia lasting fourteen to fifteen days.

The pulse throughout varied more or less with the temperature. During the first three attacks of fever it varied between 90 and 116, but during the fourth attack it tended to be faster, being usually over 100, and sometimes going up to 114–120. In the apyrexial intervals the pulse was normal.

The pyrexial attacks were all more or less alike—a fairly sudden onset, the fever reaching its height in about two days and persisting at its height for five to ten days, then falling by gradually increasing morning remissions like the lysis of ordinary typhoid fever. During the early stages of each pyrexial attack there were occasional rigors, headache was present more or less throughout the attack, there was occasional vomiting, and the defervescence was

associated with considerable sweatings. The patient was always quite clear mentally, and never really seemed quite so ill as the fever suggested. There was never any diarrhoea.

There was a slight leucocytosis during the first pyrexial attack, but practically none later. On the fifteenth day of illness, that is, about the end of the first attack, the leucocyte count was 11,200; about the middle of the second relapse the leucocytes numbered 8,800, and during the third relapse they only numbered 7,000.

On the second day of the second relapse (thirty-sixth day of illness) we withdrew 6 c.cm. of blood from a vein and made cultures in broth and in sterilized ox bile, and obtained a pure growth of an actively motile Gram-negative bacillus which proved to be *B. paratyphosus* A. It fermented glucose and mannite but with scanty gas production, gave no change in lactose, turned milk acid, and agglutinated strongly only with a specific paratyphoid A serum. During the third relapse and during the height of the fourth relapse we again obtained pure cultures of *B. paratyphosus* A from the blood. A point worthy of note is that the primary cultures required three and four days' incubation before growth became apparent.

On the thirty-ninth day of illness, during the height of the second relapse, we tested the agglutination reaction of the patient's serum against known organisms, using the macroscopic method, and found that it gave a positive reaction with *B. typhosus* up to 1 in 40 dilution, but with *B. paratyphosus* A a positive result could not be obtained beyond a dilution of 1 in 5. The reaction with *B. typhosus* was probably dependent upon two antityphoid inoculations which the patient received in November, 1914. On the fifty-second day of illness—that is, during the apyrexial interval after the second relapse—we tested the agglutination reaction of the patient's serum against a known strain of *B. paratyphosus* A, and also against the *B. paratyphosus* A isolated from his own blood, but failed to find any evidence of a positive result in a dilution of 1 in 20.

We prepared a vaccine from the organism isolated from the patient's blood, and two to three days before the termination of the third relapse administered an initial dose of 20 million. There were no ill effects, and three days later we gave a second dose of 40 million. Three days after the administration of the second dose of vaccine we estimated the agglutination titre of the patient's serum against the autogenous *B. paratyphosus* A, and found a partially positive result up to a 1 in 40 dilution. The supernatant fluid in the agglutinating tubes was not clear, but several small clumps floated about, and some were deposited. A week after the second dose of vaccine we administered a third dose of 80 million, and six days later found the agglutination titre of the patient's serum to his own *B. paratyphosus* A to be raised to 1 in 80, with a trace at 1 in 160. Nine days after the third dose of vaccine we gave a fourth dose of 120 million.

The administration of the vaccine was commenced shortly before the termination of the third relapse, and as the apyrexial period following this relapse—nearly three weeks—was much longer than either of the preceding intervals, we imagined that we had overcome the infection. Our hopes were dispelled, however, when the fourth attack set in. Nevertheless, during the fourth relapse the agglutination titre of the patient's serum to his own paratyphoid A bacillus was found to be considerably raised; a positive result was obtained up to a dilution of 1 in 600, with a definite trace up to 1 in 1,000.

Probably the dosage of vaccine was too small, but we were dealing with an acute case of unusual type, and had had no experience of paratyphoid A vaccine in treatment, so that we preferred to feel our way with smaller doses in the first instance.

The long duration of the illness, with pyrexia and apyrexial intervals, perspirations, and absence of diarrhoea, gave it a certain resemblance to Malta fever, and on several occasions we tested the agglutination reaction of the patient's serum against *M. melitensis* and *M. paratuberculosis*, with uniformly negative results.

The faeces and urine were only submitted to us for bacteriological examination twice—once during the second relapse and once during convalescence, twenty-seven days after the termination of the last relapse. On both occasions we failed to recover any paratyphoid or other organisms of the typhoid-dysentery group.

We have not been able to determine the source of infection. We have made inquiries of the M.O.H. for the district in which the patient lived after arrival in this country, but cannot trace any possibility of infection there. If he contracted his infection in Gallipoli this would entail an incubation period of at least three and a half weeks, but it is, of course, possible that he acquired the disease at Malta or even on board ship.

Summarizing the principal features of the case, we note:

1. A relapsing fever, due to infection with *B. paratyphosus* A.
2. Cultivation of the organism from the patient's own blood during the relapses.
3. Absence of diarrhoea.
4. Little or no leucocytosis.
5. Attempt to treat the infection with autogenous vaccine.
6. Absence of agglutinins to the infecting organism until after inoculation of vaccine.

We desire to express our indebtedness to Lieutenant Home Ross, R.A.M.C., from whose notes and charts the above account of the clinical aspect of the case was made.

NEW APPARATUS FOR BACTERIAL FERMENTATION TESTS: FERMENTATION BULBS.

By S. DELÉPINE,

DIRECTOR OF THE PUBLIC HEALTH LABORATORY, MANCHESTER.

Soon after the beginning of the war the price of various sugars and other products used in fermentation tests was so high, and it was so difficult to get sufficient stocks of them, that it became at times impossible to carry out all the tests required for the identification of bacilli isolated from the very large number of cases which had to be examined bacteriologically in Manchester for the 2nd Western Military Hospital.

To meet this difficulty I adapted a method which I devised about sixteen years ago and have used from time to time for the purpose of studying, collecting, and measuring the gases generated by definite quantities of fermentable fluids. In order, however, to meet the difficulty mentioned above, I reduced the size of my apparatus to a minimum.

This small fermentation apparatus consists of a tube 4 to 5 cm. in length, with a 2 or 3 mm. internal

1. Burette containing one of the sterilized fermentable media. The medium has been sterilized in the burette. The capillary delivery pipe is protected by a glass sheath until it is going to be used.

2. Fermentation bulb (sterilized) ready to be filled with the fermentable medium through the capillary delivery pipe of the burette. (A long hypodermic needle is suitable for this purpose.)

3. Fermentation bulb in a sterilized supporting glass tube. Sets of these tubes containing series of fermentable media are kept ready for use in racks.

4. Fermentation tube taken out of its supporting tube and inoculated by means of a platinum or palladium* needle. A Pasteur's pipette of suitable shape can also be used in the same way, but care has to be exercised to avoid an excess of fluid.

5. Result of a test with production of gas and change of reaction of the medium.

*Owing to the difficulty of obtaining platinum at the present time, I have adopted palladium as a substitute for platinum, after ascertaining that this metal has no appreciable lethal action on bacteria.

bore. The closed end of the tube is in the form of a small bulb, measuring 7 or 8 mm. in diameter, and of a capacity not exceeding 0.5 c.cm. The tube looks very much like the bulb end of a thermometer. These little tubes are inserted mouth downwards into other glass tubes of suitable diameter, which are themselves kept vertical by being inserted into the holes of a wooden rack. The bulb of the fermentation tube closes the upper end of the supporting tube. The two tubes can be sterilized together

by steam. After sterilization they must be thoroughly dried in the hot-air oven.

To introduce the fermentable medium into the bulbs, special burettes are used provided with a capillary delivery tube which can be pushed down to the bottom of the fermentation bulbs.

Each burette contains enough fluid to fill about 100 fermentation bulbs. After the burettes have been filled with the fermentable fluid, they are sterilized with their contents, the delivery pipe being protected by a glass sheath. When the fermentable tubes have to be filled they are held vertical, mouth upwards; the delivery tube (after flaming it, if it has been exposed to contamination) is inserted to the bottom of the fermentation bulb, and enough fluid is allowed to flow to fill the bulb, and about 8 to 10 mm. of the stem. The tube is then inverted and placed again mouth downwards in the supporting tube.

A set of tubes with the various fermentable media can easily be arranged in the rack provided for the purpose. A great number of such sets can quickly be prepared.

It is best to place these racks with the fermentation tubes ready for use in the incubator at 37° C. for twelve hours previous to using them. At the end of that time any gas which may be in solution in the fluid will have separated in the shape of minute bubbles. This gas is got rid of by shaking the bulb like a clinical thermometer and heating the tube gently near the free surface of the fluid.

When the bulbs have been prepared in this way they can be kept for several weeks ready for use. The fluid remains in position, provided the tubes have been filled exactly as stated above. When the bulbs have to be stored for several days before being used, it is best to keep them with the bulb down, the mouth remaining protected by the supporting tube.

The fermentation tubes are easily inoculated by means of a platinum needle or loop brought in contact with the surface of the fluid, and gently shaken in it. The needle must be removed carefully, so as not to cause any of the fluid to be carried to the mouth of the tube. This does not happen readily if the tubes are kept mouth upwards during inoculation.

All the reactions which can be observed in other kinds of apparatus are observed clearly in my bulbs, which present important advantages over the Durham's tubes at present in general use:

1. The total amount of gas generated under aerobic and partly anaerobic conditions out of a certain amount of medium is collected.
2. The first stages of the reaction are easy to observe, can be detected very early, and can be easily timed.
3. The colour of the litmus, when this indicator is used, is not affected by sterilization as it is in the Durham's tubes.
4. The amount of fluid used is very small.
5. The fermentation bulb is not expensive.

The fermentation bulbs can easily be prepared in the laboratory, or they can be obtained from Messrs. Charles Hearson and Co.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TWO CASES OF TETANUS TREATED SUCCESSFULLY BY SUBDURAL INJECTIONS OF ANTITETANUS SERUM.

I HAVE treated many cases of tetanus in China, India, and, during the war, in France, but have hitherto been unable to save a single one of them.

Every treatment has been given a trial—magnesium sulphate intraspinally, Baccelli's carbolic acid injections, antitetanic serum intramuscularly, chloral, bromides, etc. Death was the result in every case. The success following on the administration of large doses of serum subdurally in two consecutive cases of tetanus is very gratifying, and, although no definite conclusions can be drawn from such a small number so treated, the result is at least encouraging.

Case 1.—A private was wounded in the lower extremity, symptoms of tetanus developed—spasm of the muscles of neck, back, and abdomen—and on January 16th the patient received 1,500 units intraspinally and 1,500 intramuscularly. Decided improvement was the result. On January 21st the trismus and other muscular spasms were increased. The above treatment was repeated, and again he improved to a certain extent. On January 26th 3,000 units were given intraspinally. On January 30th the temperature rose high and risus sardonius was marked; 1,500 units were given subdurally through a drill hole in the cranium, and 3,000 units intramuscularly also. On February 15th, 1916, gradual and uninterrupted recovery was noted. I have to thank Captain H. Chapman, R.A.M.C., for giving some of the injections, and for the notes of the case.

Case 2.—A sepoy showed advanced symptoms when this treatment was commenced—risus sardonius, locked jaws, and opisthotonos. In three days he was given 9,000 units intraspinally (in addition to local treatment), and great improvement was remarked. During the next week he received 36,000 units intravenously and intramuscularly. His recovery was uneventful, although he is still very weak and emaciated. Temporary Lieutenant Daboo, I.M.S., assisted in giving these injections.

Neither of these cases had received a prophylactic dose of serum.

Major, I.M.S.

Reviews.

TYPHUS FEVER.

IN his recent book on exanthematic typhus, Dr. JEANNERET-MINKINE¹ states that he has treated hundreds of cases and seen thousands, and, in addition, has had a severe attack of the disease himself. His claim to speak with some authority upon the subject may therefore be accepted.

The incubation period varies from six to fifteen days, but is usually a week; the patient often feels unwell for several days before the onset, and may even have irregular fever. At the onset a rigor is not the rule; the temperature rises to over 102° F. in the first twenty-four hours, the conjunctivæ are congested, the face is flushed, and a scarlatiniform prodromal rash may appear, vanishing next day. The spleen enlarges at once and is often palpable, usually returning to its normal size a week later. The patient may not feel ill early in the disease; the author himself ascended the Acropolis at Athens and enjoyed seeing the Parthenon, went on to Brindisi, and passed a medical inspection during the first three days of his attack; twenty-four hours later he was in a state of coma vigil. Nausea and vomiting are often among the early symptoms, with sore throat or bronchitis. On the fourth day the patient rapidly becomes seriously ill and has rigors. The characteristic rash comes out on the fifth day, a macular roseola that is easily overlooked; petechiæ are seen in only 10 per cent. or less of the patients, and in those who are over 45 years old. The rash disappears in from four to eight days. During this period of his attack the author was, he says, in an agreeable bellicose delirium. Constipation is often present, the mouth tends to be dry and foul; there is no special odour about well-kept typhus patients. Complete insomnia is a common feature of this period of the disease, with stupidity in the milder cases, delirium in the severer. The twelfth day is often a critical period, with syncope and a temperature rising to 106° F., a thready pulse, and the pupils contracted or dilated; death occurs at this time in three-quarters of the fatal cases. Otherwise the temperature falls by lysis in three or four days, during which the patient becomes much less ill. Convalescence is more rapid than it is after an attack of typhoid fever, though the heart's action is often weak, and there may be shortness of breath on exertion for several months.

Dr. Jeanneret-Minkine recognizes various milder forms of typhus fever: abortive types of the disease ending abruptly in a week; benign forms with mild fever lasting

up to a fortnight; typhus fever without any rash, in 5 per cent. of the epidemic cases; petechial forms with a relatively good prognosis occurred frequently at the end of the Serbian epidemic of 1915; and adynamic types of typhus, often with low fever and very rapid pulse, among the well-to-do patients. The rash may appear from the fourth to the seventh day; sudamina on the chest are common, herpes labialis is not rare; in general the severity of the disease varies with the degree of development of the roseolar rash.

The cardiac symptoms are important; the pulse-rate is 100 to 120 after a few days in the severe cases, and the arterial tension is low; the heart becomes dilated in the second week, when venous thrombosis and gangrene of the extremities may occur, signs of bad omen. The spleen enlarges at first, as has been noted already; at autopsy it was of normal size in nine out of ten fatal cases. The lymphatic glands are not generally enlarged. Suppurative parotitis is a frequent and serious complication; it often leads to very great wasting. Jaundice is not common in typhus not complicated by recurrent fever; the abdomen shows no characteristic physical signs, but albuminuria and acute nephritis are not rare. About half the cases seen in the Austro-Serbian epidemic of 1914-15 had bronchitis or laryngitis; bronchopneumonia should be suspected in patients with fever lasting more than fourteen days.

The severity of the mental or psychological symptoms is very characteristic of typhus fever; even the mild cases have very severe headache and talk little after the fourth day. Toxic delirium, usually of a quiet type, is the rule; the patient is comatose, and so the delirium is agreeable. Mental confusion (from exhaustion) is not rare during convalescence; mania may also occur. Deafness without otitis is often seen, and clears up.

The blood showed a slight leucocytosis in eight cases examined by the author during the second week. *Post mortem* the blood, it is said, is unusually fluid, the renal cortex is often congested, and the cutaneous arterioles in the roseolar macules show necrotic or inflammatory changes.

Discussing the prognosis, the author states that at the beginning of the Serbian epidemic in November, 1914, the mortality was 15 per cent., rising three months later to 60 per cent.; in May, 1915, at the end of the epidemic, it fell to 15 per cent. There were 120 cases among the medical men in Serbia, with a mortality of 70 per cent. The prognosis varies with the race, and was five times better among the Russian prisoners than among the Serbians and Germans. It is better among the well-to-do and the courageous than among the poor and depressed; patients over 50 years of age did not recover, in the author's experience, and female generally did better than male patients.

The disease is transmitted by the louse, and only so five days after the louse has ingested infected blood; the louse can then transmit the infection for a period of two days. Experiments upon apes have shown that the virus of typhus fever becomes very much more virulent by its five days' sojourn in the louse; and further passages from human patients to lice exalt the virulence of the infection still further. The author thinks that in all probability bugs cannot transmit typhus, and is almost sure that fleas cannot; he believes, with Nicolle, that the virus is a filter-passing protozoon.

Treatment of the disease consists in putting the patient to bed in the fresh air; supporting the heart by digitalis, strophanthus, large injections of camphorated oil, injections of rum, and injections of adrenalin if syncope attacks occur. Antipyretic drugs should be carefully avoided; hydrotherapy is excellent for the reduction of the pyrexia. The patients should be encouraged to take plenty of fluid, and the mouth should be kept as clean as possible. Lumbar puncture is indicated in cases with prolonged coma or deafness. A recent paper by three German physicians (*Berl. klin. Woch.*, 1916, liii, p. 178) attributes excellent results to the treatment of typhus with large doses of the drug optoquin (*BRITISH MEDICAL JOURNAL*, 1915, ii, p. 542), the alleged specific against pneumococcal infections. From 1 to 2.5 grams of optoquin should be given daily by the mouth so long as the patient can swallow. When coma supervenes the drug may be administered, dissolved in oil, by hypodermic injection. It

¹ *Le typhus exanthématique.* Par le Dr. M. Jeanneret-Minkine. Paris: Librairie Payot et Cie. 1915. (Cr. 8vo, pp. 189; 1 plate. Fr. 2.50.)

is said that optoquin cuts short the febrile period in typhus fever gradually, and lessens the mortality of the disease.

So far as prophylaxis is concerned these authors, like all others, emphasize the importance of destroying the louse in every way possible; in addition, they recommended that all persons who have to do with typhus patients or run great risks of infection should have all the hair shaved from every part of their bodies, so as to minimize the cover and hold left for the lice. Dr. Jeanneret-Minkine devotes over sixty pages to the description of the louse and of the measures that should be taken to destroy it in countries where it is common, at frontier stations, in armies, and in hospitals.

PARATYPHOID FEVERS.

PROFESSOR CARLES of Bordeaux has written a useful little book on paratyphoid fevers,² based on an experience of 170 cases seen in France during the war. Paratyphoid bacilli were cultivated from the blood in 107 of the cases, the A variety in 67, the B in 40. Great stress is laid on the variety of the clinical aspects of paratyphoid fever, which may simulate with considerable accuracy attacks of meningitis, cholera, influenza, food poisoning, and acute dysentery; although it is recognized that the disease usually resembles a frank attack of typhoid. In spring and summer paratyphoid fever is benign; in bad weather and winter its mortality may reach 6 per cent. Professor Carles finds the onset usually sudden, even "brutal"; during the disease the arterial tension is low, the temperature often irregular and "spiky" on the chart; attention is drawn to the paratyphoid rashes, which are sometimes morbilliform, scarlatiniform, or even purpuric, and are most prominent in the severest cases. The febrile period lasted for six to ten days in 16 cases, ten to twenty days in 50 cases, twenty to thirty days in 63 cases, one to two months in 38 cases, three months in 2 patients, and four months in one instance. During convalescence the patient often has persistent gastro-intestinal troubles. Relapse occurred in 20 of the 170 instances.

As for the chief complications, perforation occurred once, intestinal haemorrhage fifteen times, haemorrhagic nephritis twice, cholecystitis with peritonitis twice, parotitis four times (once with suppuration, incision, and recovery), and phlebitis in two patients. The author observes that there may be no intestinal lesion present in fatal cases of paratyphoid, as is, indeed, also the case with enteric fever; as a rule the large intestine is more seriously affected than the small in paratyphoid, and fibrinous pericarditis was twice recorded. Eight of the 170 patients died, 3 of bronchopneumonia, 2 of haemorrhage, and 3 of tuberculosis, parotitis, and perforation respectively.

Professor Carles goes very thoroughly into the question of the diagnosis of paratyphoid fever, which is entirely a matter for the laboratory; it is simulated by blood infections with *B. typhosus*, *Micrococcus tetragenus* (7 cases met with), *B. coli*, and various diplococci, and streptococci that are Gram-positive (12 cases). Here the diagnosis can only be made by blood cultures, though it can be checked by agglutination tests; the evidence may be very confusing, as in the case of a patient whose blood gave positive cultures of *M. tetragenus*, no growths of typhoid or paratyphoid A and B bacilli, but did agglutinate the last three. As the author points out, repeated blood cultures and examinations of the stools and urine for these bacilli would have to be made and would have to prove negative before it would be legitimate to conclude that they were definitely absent in any given case. He has employed vaccine treatment in only four cases, and concludes that it is effective. The book is well written, and should be in the hands of all who have to diagnose or deal with typhoid and paratyphoid fevers.

ANAESTHETICS.

To emphasize the importance of maintaining thorough and unembarrassed breathing during anaesthesia, Mr. GARDNER states, has been his main object in writing *Surgical*

Anaesthesia.³ This teaching is in harmony with modern views on anaesthesia, and is unquestionably correct. The exposition of the subject is clear and precise, although in some instances the procedures suggested appear to be unduly severe. The last nine chapters offer useful hints. That dealing with emergencies errs on the side of brevity. In the present, the second edition, fresh sections have been added on spinal analgesia, intravenous ether infusion, intratracheal ether insufflation, and on Crile's anoci-association. The descriptions and directions given, however, are inadequate in view of the complicated techniques involved. No mention is made of the lateral position during intradural injection, although it is that commonly employed; in some cases it is indeed essential. Professor Meltzer's name as the originator of the intratracheal insufflation method should, we think, be mentioned when the method is described. In giving a description of the Vernon Harcourt chloroform inhaler, Mr. Gardner quotes a trade circular, although the British Medical Association, in its published report of the Special Chloroform Committee, gives a full and accurate account of the apparatus. Some slips occur which should be corrected in future issues. Thus, Sir Frederic Hewitt and Sir T. Lauder Brunton are repeatedly called Dr. Hewitt and Dr. Brunton. Mr. Gardner still adheres to the alkaline treatment of acetonaemia arising after anaesthesia, and regards post-anaesthetic vomiting as due to a central nervous cause, and not to gastric irritation set up by the swallowing of condensed anaesthetic vapour. In spite of minor blemishes the book should prove useful, for its pages focus much valuable instruction. The illustrations are good and help to elucidate the text.

The first edition of Dr. HERTZLER's excellent book on *Local Anaesthesia* was reviewed in the *BRITISH MEDICAL JOURNAL* less than two years ago. The second edition⁴ is half as large again as the first and has many more illustrations; without giving an extended review of the book's undoubted merits, it suffices to say that it gives a thoroughly sound and practical account of the subject, and may be recommended to the attention of all who are in search of a trustworthy exposition of the surgical operations possible and advisable under local anaesthesia.

COLLOID CHEMISTRY.

THE study of colloid chemistry has made great strides during the last few years, largely owing to the energy and initiative with which it has been pushed by WOLFGANG OSTWALD. He is the author of the most authoritative book on this highly complex subject, and an American translation of the third edition of his handbook has now been made by Dr. M. H. FISCHER, with the assistance of Drs. OESPER and BERMAN.⁵ The volume is divided into three parts. The first gives a practical introduction to the science; Part II contains an account of general colloid chemistry; the third part is devoted to the consideration of special colloid chemistry. The science is one of increasing importance, not only from the point of view of the knowledge of the properties of matter, but also from the practical standpoint. A brilliant contribution to the study of colloid chemistry as applied to the science of physiology has recently been published by Professor Bayliss (*BRITISH MEDICAL JOURNAL*, 1916, i, 279) in this country; from the practical point of view it may be noted that rubber is a colloid of ever-increasing commercial importance, and, as a sop to Americans, it may be added that the national dish ice-cream is a chemically heterogeneous water colloid second in lickerishness to none of those that appear on the table. Colloids exist in vast numbers and in very various forms; the terminology of the subject is still in a state of flux, and this fact undoubtedly militates against its intelligibility to the inexperienced reader, whether he be a chemist or no. Perusal of Ostwald's book leads

⁵ *Handbook of Colloid Chemistry; the Recognition of Colloids, the Theory of Colloids, and Their General Physico-Chemical Properties*. By Dr. W. Ostwald of Leipzig. First English edition, translated from the third German edition by Dr. M. H. Fischer, Professor of Physiology in the University of Cincinnati, with the assistance of Dr. R. E. Oesper and Dr. L. Berman.

² *Les fièvres paratyphoïdes*. Par le Prof. J. Carles. Les Actualit s M dicales. Paris: J. B. Baill re et Fils. 1916. (Cr. 8vo, pp. 96; 15 figures. Fr. 1.50.)

one to the conclusion that as the protagonist of the present science of colloid chemistry he has a rival in von Weimarn, a prolific author with whom he finds himself in perpetual conflict. The book is written clearly, but it has been translated without any attempt at literary style, and is disfigured by numerous misprints. It furnishes abundant references of the literature of the subject up to the year 1910, and should be in the hands of all who wish to make a serious study of the subject.

NOTES ON BOOKS.

A COLLECTION of the occasional writings of Dr. A. LEWERS,⁶ of Melbourne, has recently been published, containing a number of brief essays on various medical points that interest the public at large. They deal with such subjects as "eugenics," "euthanasia," "physical culture," "diathesis," "alcohol," and fifty other such topics. Dr. Lewers writes clearly and holds soundly conservative views on the matters with which he deals. There is hardly room for much originality of thought or diction in a book such as this; yet the essays make pleasant reading and may be recommended as a successful attempt to teach the layman common sense in medical matters of general interest.

The thirty-first annual report of the *American Climatological Association*⁷ contains a number of slight but interesting articles on medical and climatological subjects. Dr. C. F. Gardiner reports favourably on the results of heliotherapy in Colorado, even in patients who have advanced phthisis and those who are of the extreme blonde type and have been regarded as unsuitable subjects. Dr. J. M. Anders discusses the antisiphilitic treatment of cardiac syphilis; Dr. G. Hinsdale sums up the evidence that goes to prove that Bright's disease is amenable to climatic treatment and improves in warm climates that are sunny and reasonably dry. The volume contains several other papers of general medical interest.

Dr. STARR has written a popular account of the general features and management of adolescence⁸ that should be of great service to narrow-minded and fussy parents. They, however, are probably the last people who would read or act on the recommendations of any such book, a fact that is to be regretted in view of the soundness and temperance of the author's opinions. The book contains six chapters, devoted to such topics as growth, physical education, the diseases of adolescence and its faults, menstruation, and the advisability of giving sexual enlightenment.

⁶ *Medicine and Meditation*. Occasional writings by A. Lewers. M.R.C.S.Eng., L.R.C.P.Lond., D.P.H.Lond. Melbourne: Ford and Son, 1915 (Post 8vo, pp. 127.)

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the committee, held on April 11th, twenty-six cases were considered and £234 granted to twenty-two of the applicants. Two additional annuitants of £20 each were elected, to be known as the Margaret Harker-Smith annuitants, the committee having recently received the amount of £1,000 from the trustees. The following is a summary of the cases relieved:

Widow, aged 70, of M.R.C.S.Eng. who practised at Heywood and died in 1894. Was left totally unprovided for, and earns a somewhat precarious living by acting as a day cook. Owing to age is unable to obtain permanent work. Relieved twice, £14. Voted £12 in twelve instalments.

M.R.C.S.Eng., aged 83, who had practised at Fulham. Practically blind, and has to help to support one of his son's family. Only permanent income a small pension from another society and the old age pension. Previous relief five times, £34. Voted £12 in twelve instalments.

Daughter, aged 58, of L.S.A.Lond. who had practised in London and is now a pensioner of the Fund. Applicant has tried to make a living by keeping a haberdashery shop, but, owing to the increased cost of commodities, is unable to make it pay. Father lives with daughter. Voted £10 in two instalments and referred to the Guild.

M.R.C.S.Eng., F.R.C.S.Edin., aged 76, married, and has practised at Lincoln and London. Owing to age and inability to get about is unable to practise. Only income a small annuity. Requires help towards the education of his youngest daughter, aged 16. Two other children married and unable to help. Voted £12 in twelve instalments.

Widow, aged 63, of M.R.C.S.Eng. who practised at Burton-on-Trent and died in October, 1915. Owing to long illness of husband, and three sons having joined the army, all her savings are exhausted. Receiving a little help from her son's employers and a little from dividends. Voted £5.

Widow, aged 74, of L.R.C.P.Edin. who practised at Ross, Mon., and died in 1889. Was left totally unprovided for, and only income a pension of £15 from another society. Lives with two nieces, who have to earn their own living. Voted £5, and referred to the Guild.

Widow, aged 45, of M.D.Edin. who practised at Sheffield and died in 1906. Was left unprovided for, and health is very indifferent. Has recently undergone an abdominal operation. One son, aged 16, at school and maintained by relatives. Previous relief twice, £20. Voted £10 in two instalments.

Widow, aged 59, of M.R.C.S.Eng. who practised in London and died in 1904. Applicant suffers from chronic rheumatism and general ill health, and has no income. Previous relief thirteen times, £133. Voted £15 in twelve instalments.

Widow, aged 62, of L.R.F.P.S.Glasg. who practised at Rothsay and died in 1899. Endeavours to make a living by taking in lodgers, but has not been successful of late. Suffers from rheumatism and neuritis. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 64, of M.R.C.S.Eng. who practised in London and died in 1914. Was left with insufficient means, and has an invalid daughter to keep. Other children only able to help slightly. Relieved twice, £24. Voted £12 in twelve instalments.

Daughter, aged 54, of M.R.C.S.Eng. who practised at Newport, Mon., and died in 1892. Is blind and health indifferent. Only income a pension of £21 from another society. Relieved five times, £60. Voted £12 in twelve instalments.

Widow, aged 46, of M.B.Edin. who practised at Strathspey and died in 1910. Was left quite unprovided for, with four children, aged 9 to 17. Tried to make a living by keeping a boarding house, but has recently had to give it up. Only permanent income a small pension from another society. Relieved five times, £50. Voted £10 in two instalments.

Daughter, aged 67, of M.D.Edin. who practised in Lincolnshire and died in 1898. Is matron of an orphanage, but owing to lack of subscriptions her salary has been suspended. Relieved once, £5. Voted £12 in twelve instalments.

Daughter, aged 58, of M.D.Edin. who practised at Kirkdale and died in 1867. Is a dressmaker, but owing to indifferent health her business has declined, and she cannot make sufficient to meet expenses. Relieved once, £12. Voted £12 in twelve instalments.

Widow, aged 68, of M.R.C.S.Eng. who practised at Sheffield and died in 1884. Has endeavoured to make a living by teaching languages, but owing to the war her pupils have left her. Has a small pension from another society. Relieved five times, £25. Voted £12 in twelve instalments.

Daughter, aged 50, of F.R.C.S.Eng. who practised at Biggleswade and died in 1890. Suffers from chronic gastritis and epileptic fits. Only income £20 from another society. Relieved seventeen times, £153. Voted £12 in twelve instalments.

Daughter, aged 60, of M.R.C.S.Eng. who practised at Peckham and died in 1885. Owing to the weak state of her health she is unable to undertake any permanent work. Lives with sister, who has to earn her own living, and is unable to help applicant. Relieved eighteen times, £209. Voted £12 in twelve instalments.

Widow, aged 58, of M.R.C.S.Eng. who practised at Sydney, N.S.W., and died in 1901. Has no income, but receives occasional help from friends. Has a house in the country which she cannot let, owing to its bad condition. Has one daughter, a professional singer, but owing to the war she cannot obtain any engagements. Relieved twice, £20. Voted £10 in two instalments.

Widow, aged 68, of M.R.C.S.Eng. who practised in London and died in 1898. Endeavours to make a living by taking in boarders, but has been unsuccessful of late owing to ill health, applicant suffering from a cancer. Has five daughters, all unable to help. Relieved seventeen times, £205. Voted £12 in two instalments through the Guild.

Widow, aged 53, of M.B.Aberd. who practised in Warwickshire and Australia and died in 1908. Was left unprovided for, with only a little help from relatives. Has three children aged 29 to 31, but none able to help. Applicant is suffering from asthma and heart trouble. Relieved seven times, £73. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

British Medical Journal.

SATURDAY, APRIL 29TH, 1916.

MILITARY ORTHOPAEDICS.

WE are glad to be able to announce that we have been given the privilege of publishing a series of articles by Lieutenant-Colonel Robert Jones, Lecturer on Orthopaedics in the University of Liverpool, whose appointment by the War Office to be Inspector of Military Orthopaedics was announced a fortnight ago. In these articles, the first of which appears to-day, he will discuss, from an experience probably unrivalled in extent and variety, the principles by which the treatment of war injuries of bones and joints and their after-consequences should be guided, and the means which surgery—by preventive measures, by operation when necessary, and by efficient after-care—affords for completely restoring or greatly improving the functions of the damaged limb.

The establishment of special military orthopaedic hospitals or sections of hospitals at various centres is proof that the chiefs of the Army Medical Service appreciate the importance of the application of the principles of modern orthopaedic surgery to the cure or relief of injuries of limbs produced in the war. It is to be feared that to a great many people the mention of orthopaedics immediately suggests elaborate instruments and special boots. But this is a mistake. The instruments and boots are really confessions of failure; the true aim of orthopaedics is to correct deformities of bones and joints so that the natural action of the muscles upon them is restored. The classes of cases which come within the scope of the military orthopaedic scheme include derangements of joints, malunited and ununited fractures, injuries to ligaments, tendons, and muscles, and injuries of nerves calling for nerve suture or tendon transplantation followed by appropriate treatment for a sufficient length of time, as well as cases requiring in the last resort the fitting of mechanical appliances.

The military orthopaedic hospitals will be concerned especially with men who have received injuries of the limbs which, while they are disabling, are yet of such a nature that orthopaedic treatment—using the word in its widest sense—affords good hope that the power of earning a living may be regained in whole or in part. Such cases must be regarded from two points of view—that of the welfare and happiness of the individual and his family on the one hand, and on the other that of national economy and the maintenance of the productive power of the nation.

It may be noted in passing that, speaking quite generally, injuries of the upper limbs are, from either point of view, undoubtedly more important than wounds of the lower, since many skilled sedentary occupations are open to men who have lost a leg, or a foot, or the free use of those parts, which cannot be filled by men who have been deprived of the use of the forearm or hand.

The Financial Secretary to the War Office, in his statement in the House of Commons on March 22nd, said that in assessing permanent pensions payable to men disabled in the war it did not matter what a man earned at the moment; what was taken into account was his capacity to earn. His pension was calculated

on his physical condition; it followed, therefore, that if there were nothing in a man's physical condition to prevent him from earning something, if so inclined, his pension would be reduced if he did not earn what he could. On the other hand, a man earning a very considerable rate of wages might at the same time be drawing a considerable pension. Mr. Forster did not deal specifically with cases other than those of amputation, but appeared to take them as exemplifying the principle by which the Commissioners of Chelsea Hospital would be guided. When a man has lost a limb he is treated by the Chelsea Commissioners as totally incapacitated for a certain length of time, and gets the full rate of pension of 25s. a week for at least two months after he has been fitted with an artificial limb. After a certain time, say six months altogether, the case is reviewed and the man's physical condition closely examined. If the medical opinion be that his physical condition is sufficiently good to enable him to earn his living to the extent of, say, one half, his pension is reduced accordingly. The amount of the reduction, Mr. Forster said, was quite irrespective of what the man was earning at the time; if his physical condition had so much improved as to permit him to earn in the open market at least half of the full living, his pension was adjusted on that account, and not on account of the particular amount of money he might happen to be earning at the moment.

The Parliamentary Secretary to the Local Government Board, in moving, on March 23rd, the vote of £1,000,000 to the Statutory Committee constituted under the Naval and Military War Pensions Act, 1915, said that the duty of the Statutory Committee is to grant pensions to supplement those granted by the Greenwich or Chelsea Commissioners, and to make provision for the training and employment of disabled sailors or soldiers. The Committee has power to grant a supplementary pension in a case in which, after consideration of all the circumstances, it appears that the State pension, either to the individual soldier or sailor or his dependants, is not adequate; it has power also to grant pensions in cases of hardship in which for one reason or another pensions have not been given to disabled soldiers and sailors. Further, it has recently been decided that State pensions may be granted in cases in which the disease has been aggravated by military service; that is to say, it will not be necessary for a man to prove that the disease from which he suffers is due wholly or directly to military service. Mr. Hayes Fisher stated that down to March 9th, 1916—a date antecedent to that on which this concession was made—the number of disabled men discharged from the army as unfit owing to wounds and disease who had been awarded pensions and grants by the Chelsea Commissioners was 30,255; 5,470 had received final pensions, 1,356 provisional pensions, and 23,429 conditional pensions, which would be reviewed later, apparently in the manner indicated by Mr. Forster on March 22nd.

We may also note here, though not directly bearing on the orthopaedic hospitals now being established, that the number of cases of amputation notified to the hospital for limbless men at Roehampton down to March 1st, 1916, was 3,818; of these, 1,628 had already been admitted to the Roehampton Hospital, and 932 had been discharged with properly fitted artificial limbs. At the date mentioned there was a waiting list of 2,027, and the cases, Mr. Hayes Fisher added, were being notified at the rate of 300 a month. In future, Scotsmen will, we understand, be admitted to the new hospital for limbless soldiers and sailors at

Glasgow, which, like the Roehampton hospital, has been established by private benevolence, with the assistance and approval of the War Office and the Red Cross.

These statistics will help to an understanding of the magnitude of the problem with which the country is confronted, for it is certain that the number of men who suffer from injuries of bones and joints not requiring amputation must be very many times greater than the number who have to be submitted to an operation so drastic, yet, if not wisely treated, many of them may be quite as badly crippled.

FAT EMBOLISM.

Fat embolism, noted by Zenker and others in 1862, was first accurately described by von Recklinghausen in 1864. His account was founded on the case of a man who died of fat embolism of the brain a few hours after being kicked by a horse on the shin; the process was investigated by his pupil Busch, who came to the conclusion that the escape of blood into the marrow of the injured bone had driven the fat into the veins.

During the last fifty years the occurrence of fat embolism has often been noted and investigated. It has been seen to follow mechanical shock or concussion without the fracture of any bone, although the traumatic or operative fracture of bones remains its commonest cause. Bürger, for example, recorded death from pulmonary fat embolism in the case of a woman who was very severely beaten with a stick on the back; the bruised and loosened subcutaneous tissues were the source of the fat in this instance. Fat embolism is said to occur frequently as a complication of osteomyelitis, and in diabetes mellitus. Its occurrence has been noted exceptionally in a number of medical conditions, such as lobar pneumonia, burns, endometritis, senile marasmus, anthrax, and poisoning by phosphorus, potassium chlorate or bichromate, or alcohol, in which there is no obvious cause for its appearance. It has, indeed, been found in the lungs in a high proportion of persons dying from all sorts of diseases. Scriba (1880) observed it in 24 out of 46 cases examined, counting a single fat-droplet in a pulmonary capillary as evidence of fat embolism. More recently, Nicolai¹ found elongated droplets or "snakes" of fat in the pulmonary vessels of 8 out of 57 cadavers; all had died of phthisis, heart disease, or renal disease, without trauma or osteomyelitis. He notes that the occurrence of occasional droplets of fat in these vessels must be regarded as normal, quoting the experience of Cornil and Ranvier, who found similar droplets in the pulmonary vessels of 18 out of 20 normal dogs. As these authors point out, the difference between the physiological and the pathological here must be one only of degree.

It is generally stated that fat embolism may be fatal through either the lungs or the brain. Nicolai quotes a case of his own in which fat embolism of the brain was the cause of death. The patient, a man of 40, was struck on the chest and leg by a falling beam. He sustained fracture of the left tibia and multiple fractures of the ribs, but lost consciousness for only a moment. Next day his temperature, respiration-rate, and pulse-rate rose, and he became mentally dull; the day after that he died comatose, the temperature rising to 104° F., the pulse to 116, the respirations to 40. At the *post-mortem* examination

fat was found in the vessels of the glomeruli and the capillaries between the renal tubules; the heart also exhibited fat embolism and parenchymatous degeneration of the muscle fibres. The brain presented highly characteristic appearances. The centrum ovale on section showed numerous small haemorrhages, which, under the microscope, displayed small vessels plugged with fat and surrounded with extravasated blood and necrotic white matter. The grey matter was free from these haemorrhagic and necrotic areas—a fact which Nicolai explains by saying that the grey matter has a better blood supply than the white. The foramen ovale of the heart was closed, and Nicolai draws special attention to the fact that his case shows that it is possible to have fat embolism of the greater circulation without the occurrence of paradoxical embolism, or the transit of fat emboli from the right auricle to the left through a patent foramen ovale. He believes that the fat reaches the circulation directly by way of the veins, but notes that Wilms (1910) and Fritsche state that it may also be picked up by way of the lymphatics, and be poured into the circulation through the thoracic duct. Wilms has even made a temporary fistula of the thoracic duct to stem the onset of symptoms of fat embolism, with success; the lymph discharged from the fistula was found to contain large drops of fat. Nicolai is of the opinion that the small and frequent pulse and the precordial pain noted in some instances of fat embolism may really be primary heart symptoms from blocking of cardiac arterioles and capillaries.

Fat embolism has been made the subject of numerous experimental investigations, such substances as olive oil or melted lard having been injected into the veins of the experimental animals. Among these investigations is that published last year by Maccagno,² who gives a rather patchy summary of the subject. It has been found that death follows if fat to the amount of about 0.2 per cent. of an animal's weight is injected into one of its veins. The fat is very slowly eliminated, partly by saponification and absorption, partly by excretion in the urine. Scriba, indeed, detected fatty droplets in the urine of 26 out of 33 patients suffering from fat embolism. Maccagno's experiments were made with lard and olive oil on rabbits, with the object of finding out, first, the size of the fatal dose; and, secondly, of determining the length of time required for the absorption of the emboli. He concludes that 0.1 per cent. of the animal's weight generally constitutes a fatal dose; but considerable individual variations were noted here, up to 0.2 per cent. of the body weight being tolerated in a few instances. The fat is slowly disposed of after injection. If small amounts are injected daily, death occurs when 0.1 per cent. of the body weight has been injected, but if the injections are made every four days, death is not caused until the quantity of fat injected amounts to 0.136 per cent. of the weight of the body. Even forty-one days after an intravenous injection fat emboli may be found in the lungs and kidneys, with more or less extensive infiltration with small round cells and fat-containing cells around the occluded vessels, and interstitial haemorrhages. Maccagno concludes that fat embolism is a cumulative process, a point that ought, perhaps, to be kept in mind in the treatment of comminuted fractures of bones and the like. The exact cause of death in his experimental animals he does not specify very clearly. Recovery after extreme dyspnoea was sometimes noted, as if great embolic obstruction to the passage of blood through the lungs

¹ A. Nicolai: *Nederl. Tijdschr. voor Geneeskunde*, Amsterdam, 1914, li 1605.

² M. Maccagno, *Il Policlinico*, Sez. chirurg., Rome, 1915, xxii, 209.

was not necessarily fatal; it may be added that in the case of human beings fat embolism is said to be fatal by means of pulmonary obstruction in a little more than half the cases (Gröndahl). Almost all Maccagno's animals died in convulsions, and showed fat embolism of the brain and heart on section; at the same time, the right ventricle displayed considerable or extreme dilatation, and oedema of the lungs which was roughly proportional to the amount of fat injected, with areas of pulmonary infarction. He is, in fact, unable to determine to what extent fat embolism of the lungs, of the heart, and of the brain are respectively to be held responsible for death in fat embolism.

The practical conclusion he draws from his experimental work is this—that patients with fractured bones should be kept as quiet as possible for several days before any operative treatment of their fractures is undertaken, in order that the injured vessels in the bones may have time to become thrombosed; in this way the danger of further fat embolism may be minimized.

TUBERCULOSIS SCHEMES.

In common with many other organizations, philanthropic and otherwise, the tuberculosis campaign has of necessity been checked in its course of activity by the national campaign against the more obvious enemy. But the work begun nearly thirty years ago and steadily pursued up to the present time has not been barren of results. Knowledge of the disease and of the means whereby its progress may be checked has been spread far and wide by various agencies throughout the kingdom, and, indeed, throughout the civilized world. Although they are all striving to the same end, these agencies have not as yet been co-ordinated, nor, except by means of scattered reports, have the experiences of each been made available for all. In order to remedy this defect and to bring all the various boards and committees into touch with one another, the National Association for the Prevention of Tuberculosis has caused a small handbook¹ to be prepared in which are recorded the answers received to a number of questions addressed to tuberculosis authorities of every degree in Great Britain and Ireland. The main difficulty of all such authorities has been to reconcile conflicting interests. In the metropolitan area a lead has been given to lesser communities by making the county council into the central organizing authority, but the detailed work has for the most part been placed in the hands of the metropolitan boroughs, who have to share with the Local Government Board and the local Insurance Committees the duty of providing dispensary and sanatorium treatment, in association, wherever possible, with the existing general and special hospitals. It is obvious that a vast amount of work has had to be done and still remains to be completed before smooth working between so many different bodies can be attained. The publication of an index, by which the extent to which the work is being carried on can be easily and quickly ascertained, is an important step in the direction of a more definite central co-ordination of which the whole antituberculosis movement stands in great need. For purposes of such reference the counties in England, Wales, Scotland, and Ireland have been separately considered, and the provisions made are set out in tabular form, a similar plan being adopted as regards the boroughs and after-care committees. Examination of these tables will show very plainly that although a great deal has been projected and approved by the authorities concerned, there still remains a very great deal to do. The

effects of the war have been keenly felt in many places, not only in the shortage of well qualified tuberculosis officers, but in lack of funds, and, in some cases, lack of accommodation, the buildings hitherto used for tuberculosis cases being now required for military purposes. The work in the English boroughs would appear to have lagged somewhat behind that in the counties, except in the provision of after-care committees, which are doubtless easier to administer in crowded than in scattered areas. Scotland and Ireland have not been behindhand either in the provision of dispensaries or sanatoriums. In Wales, the King Edward VII Welsh National Memorial has done a great deal of valuable work, except in Pembrokeshire, where the authorities would appear to be unwilling to co-operate in a common scheme for the whole Principality. The work of co-ordination thus started under the auspices of the National Society is deserving of recognition, support, and assistance from all the tuberculosis authorities concerned, for every one of them may, directly or indirectly, profit by it as experience increases, and the need for mutual interchange of ideas becomes more distinctly felt.

THE CONTROL OF TYPHOID FEVER.

A DETERMINED effort is being made in New York to reduce the prevalence of typhoid fever, and the results are already very encouraging. The number of deaths per 100,000 of the population has fallen from 14.78 in 1905-09 to 6 in 1914. Every case of typhoid fever in New York City reported to the department of health is visited by an inspector, who makes careful inquiries into the history of the case and records the facts elicited on a special history card. The cards are analysed by the chief of the division of epidemiology, and if necessary additional investigations are undertaken to learn the source of infection and to prevent its further dissemination. It is not believed that all the cases come to the knowledge of the department of health, but it is thought that over three-quarters do. One result of the investigation of the whole mass of material by Dr. Charles F. Bolduan, director of the Bureau of Public Health Education, has been to show that a considerable proportion of the cases of typhoid fever occurring in New York and other cities in the United States arise in rural districts. Thus, in 1915 in New York, out of 874 cases the origin of which was definitely traced, 484 were of rural origin—that is to say, the infection was in 372 cases contracted outside the city, and in 112 was due to milk infected at a creamery. As 2,456 cases altogether were reported those definitely attributable to extra urban infection constituted at least 20 per cent. In 1905 they were estimated to constitute 50 per cent., and this great reduction is attributed to two measures—the effective chlorination of all the water of the Croton supply, and the effective pasteurization of milk. It is also considered that the small proportion of cases due to direct exposure to another case (165), and of those due to the consumption of food contaminated by flies carrying typhoid infection (95) is very creditable to the sanitary conditions and medical supervision of the city. It is, however, added that, as typhoid immunization is now everywhere recognized as an efficient preventive, all who are called upon to treat cases of fever should insist on the use of this valuable prophylactic in order that the occurrence of the infection through direct exposure may be reduced to a minimum. No cases were attributed during the year to the ingestion of water or oysters, but 118 were found to be due to carriers. The rate of deaths from typhoid fever in New York is still much too high, however, compared with London, Berlin, Hamburg, or Vienna; it is possible that by the continuance of the system of inspection of every case the source of a larger proportion of those now unknown may be discovered; at any rate, what has already been accomplished will encourage the department to persevere.

SHAKESPEARE'S ENGLISH IN ULSTER.

IN an article entitled, "Shakespeare and the Ulster dialect," which appeared in the *Northern Whig* of April 22nd, Sir John Byers has made a very appropriate and interesting contribution to the literature of the tercentenary we are now celebrating. Many of the words and phrases used by Shakespeare which have since been lost are still found in the dialect of his native Warwickshire and the surrounding counties; and as it was from those districts that many of the English colonists went to Ulster at the time of the great Plantation in the reign of James I, a large number of those words and phrases are still found in the local speech of Ulster. Sir John Byers says that until the end of the eighteenth century there was a tradition in that province of Ireland that pure English was spoken at Lisburn, and so recently as in 1878 it was estimated that while a glossary of more than 2,000 words would be required to enable a modern Englishman to read Shakespeare, probably one of about a tenth of that number would be all that would be needed for the same purpose by an intelligent person who had learnt his mother tongue in the North of Ireland. "Many of the so-called 'vulgarisms,'" says Sir John, "met with in the spoken language or dialect of the people of the North of Ireland, belong to the Augustan age of English literature, and have come down from the period of Queen Elizabeth through the English planters. These people, having once acquired the vernacular English of that wonderful time, have fortunately handed it down through their descendants as a spoken language, despite the absurd attempts of some pedants to stamp it out." As a result this vigorous English, with its supposed "vulgarisms," used with such effect by Sidney, Spenser, Bacon, Ben Jonson, Marlowe, and, above all, Shakespeare, "has added greatly to the recognized force, the crisp clearness and the subtle humour of the Ulster dialect." A number of illustrative quotations show the zeal with which the distinguished gynaecologist of Belfast has laboured in a comparatively unexplored field of Shakespearean study. The limits of our space will allow us to give only one or two examples of more or less directly medical character. "Child" or "chile," used in Ulster for a female infant, is found in *A Winter's Tale*:

Mercy on's, a barne; a very pretty barne!
A boy or a child, I wonder?

A North of Ireland doctor often hears that a patient cannot "digest (disgist)" his food, or that he is suffering from "indigestion." This form was common in the sixteenth and seventeenth centuries; it is found in *Julius Caesar*:

This rudeness is a sauce to his good wit
Which gives men stomach to digest his words with better appetite.

Hamlet says: "The toe of the Pesant comes so neere the heeles of our courtier, hee galls his kibe." Sir John Byers says that "kibe," or "kibey heel," is used in Ulster in the sense of a sore or chipped heel, often the result of chilblains. "Puke," meaning to vomit, still survives in Ulster. Sir John Byers says that Shakespeare was the first writer to use the word; that was in 1599 or 1600, and there is no other instance of its employment by him.

THE SPIROCHAETE OF WEIL'S DISEASE.

As was noted in the *BRITISH MEDICAL JOURNAL* of April 1st, page 491, the spirochaete that causes epidemics of infectious jaundice in Japan has lately been discovered by Inada, and the disease to which it gives rise has been identified with what is known as Weil's disease in Europe. Drs. Ito and Matsuzaki have recently succeeded¹ in cultivating this spirochaete, which is known as *S. icterohaemorrhagiae*, on a variety of media besides Noguchi's, and have published full details of the methods and media

they have employed. It would seem that this spirochaete is not so fanciful a feeder as had been supposed. It will grow on either solid, semi-solid, or fluid media, and is a facultative anaërobe. The solid and semi-solid media must contain blood, such as that of the guinea-pig, which has the disadvantage of making them opaque; blood agar and blood gelatin have both been used with success at any temperature between 15° and 37° C., and with or without the addition of a supernatant layer of liquid paraffin. No odour, gas formation, or liquefaction of the media were observed, and the growth was slow. Of the various fluid media employed, a pleural exudate rich in fibrin gave the best results. It appears that the method of multiplication of the spirochaetes is still undetermined, whether by longitudinal or transverse division. The organisms do not take any of the ordinary aniline dyes, but assume a pinkish or purplish colour when stained with Giemsa's solution. The authors have cultivated three different strains of the *S. icterohaemorrhagiae*, and find that the organism retains its pathogenicity for guinea-pigs through many generations.

TROPICAL SANITATION.

IN an address to the Conference of Health Officers of New York, held recently at Rochester, Surgeon-General Gorgas said¹ that the great awakening in tropical sanitation during the last twenty years had its first beginning (he was speaking, no doubt, of America) in the Spanish-American war (1898-99). It had been known for three or four hundred years that military expeditions in which large bodies of white troops were required could not be undertaken in the tropics on account of the loss from disease. The French army in Santo Domingo in 1798, out of a total strength of 25,000, lost over 22,000 from yellow fever, and four years later, out of a total of 40,000, it lost 20,000. Where the disease prevailed it was equally fatal to the civil populations, as was shown by the United States records and those of Spain. About the beginning of the nineteenth century there seemed to be a serious risk of yellow fever spreading over the whole world. It was evident that the epidemics which visited the United States were imported from Havana. When that city fell into the hands of the Americans in 1898 every effort was made to control the disease. In 1900 it had been made one of the cleanest cities in the world, but yellow fever was worse than it had been for years. The antimosquito campaign in Havana was begun in February, 1901, and the disease was eradicated in September of the same year, and had since then practically disappeared in the northern hemisphere. In 1898 Sir Ronald Ross had demonstrated that malaria was conveyed from man to man by another species of mosquito, the *Anopheles*, and the same conditions existed as to the transmission of malaria as with that of yellow fever. It was evident, therefore, that a very slight extension of the measures taken for the repression of yellow fever should be sufficient against malaria, and this had proved to be the case. A brief account of the sanitary work done during the construction of the Panama Canal was given and Gorgas showed how near it came to failure in the beginning, before the members of the Commission were won over to the views of the sanitarians. In June, 1905, they asked that Gorgas and his fellow workers should be replaced by "men more practical and sane." Fortunately, this request was not acceded to, and the last case of yellow fever occurred in Panama in September, 1905; since then only one case had occurred in the Republic. Sanitary conditions also rapidly improved in other ways, and soon the isthmus, in respect of health, compared favourably with many parts of the United States. Gorgas attributed the extraordinary improvement in the general health conditions of Panama to the social betterment caused by the high wages paid the workers. He added that if such

¹ *Journ. Experim. Med.*, Baltimore, 1916, xxxiii, 557.

¹ *Journ. Amer. Med. Assoc.*, December 25th, 1915.

wages were paid now in New York, "all the poverty, sickness, and degradation caused at present by low wages would be rapidly ameliorated." He had laboured in a field where great results in the improvement of the public health had been achieved, but he was sure that these would be small compared with the results that would be produced by the payment of a sufficient wage to the toiler.

CONTROL OF PETROL SUPPLIES.

THE President of the Board of Trade has appointed a committee "to control the supply and distribution of petrol, and to consider what measures are necessary to the national interest (1) to ensure that adequate supplies of petrol shall be available for the purposes of war and for other essential needs; (2) with the above object to regulate the use of petrol for other purposes in the United Kingdom during the period of the war; and, subject to the direction of the Board of Trade, to give executive effect to the measures decided on." The members of the committee are Mr. Oliver Bury (chairman), Mr. Albert Edward Bowen, Sir John Prescott Hewett, G.C.S.I., and Mr. Philip G. L. Webb; the secretary is Mr. H. W. Cole, to whom communications may be addressed at 29, Abingdon Street, Westminster, S.W. The Committee will not consider individual applications for supplies of petrol. A few weeks ago a communication was addressed to all medical practitioners asking them to answer certain questions with regard to their use of petrol-driven vehicles, and the amount of petrol consumed. We are informed that some 8,000 or 9,000 members of the profession have as yet failed to return the form of inquiry. It is important that this should be done whether or not the practitioner uses a car or motor cycle, in order that full statistics may be laid before this committee, which, as will be noted, has executive powers, and will have to estimate the amount of petrol which should be liberated for the use of medical practitioners. Any members who may have mislaid the form can obtain another on application to the Secretary, National Health Insurance Commission, Buckingham Gate, S.W.

ARSENICAL NEPHRITIS.

MEDICATION with arsenical drugs is in all probability more general nowadays than ever before. The most recent arsenical preparations are chemical substances that are supposed to attack the organisms of disease rather than the tissues of the patient—to be, that is to say, parasitotropic rather than organotropic, in Ehrlich's nomenclature. Yet even with the use of the best types of arsenical compounds, such as salvarsan, kharsivan, neo-salvarsan, galy, and the like, cases of poisoning occur from time to time, and acute nephritis is one of the forms in which this arsenical poisoning makes itself manifest. Drs. Pierce and Brown¹ have recently investigated this nephritis in guinea-pigs treated with toxic but sublethal doses of various arsenical drugs. Speaking generally, they find the renal changes here to be much the same in dogs as they are in guinea-pigs; the arsenical compounds used were arsenious acid, arsenic acid, sodium cacodylate, salvarsan, neo-salvarsan, arsacetin, arsenophenylglycine, and atoxyl, and they were administered by intraperitoneal injection. The authors find that the renal changes are of two main varieties: In one of these the kidneys are red, hyperaemic, and haemorrhagic; the toxic lesion is mainly vascular. Arsenious acid, arsenic acid, sodium cacodylate, salvarsan, and neo-salvarsan all produce an acute nephritis of this type, with comparatively little necrosis of the tubal epithelium. The other variety of nephritis is that produced by arsacetin, arsenophenylglycine, and atoxyl; here the main lesion is tubal necrosis, the vascular injury is subordinate. There is a more or

less rapid attempt at regeneration of the epithelium of the secreting tubules; numerous mitoses are seen in the microscopical sections, and there is a well-marked leucocytic exudate in the interstitial tissue. In both types of nephritis there may be pronounced proliferation of the fibroblastic cells in both cortex and medulla of the kidney. The general conclusion to which the authors come is this, that various arsenical drugs may inflict injury mainly or entirely upon either the vascular, the epithelial, or the interstitial tissues of the kidney in different cases; the injury to the interstitial cells can only be estimated by the examination of the kidneys when some little time has elapsed for the processes of stimulation or repair to show themselves. They hold that the mode of action of an arsenical compound as a renal toxic agent is bound up with the chemical constitution of the drug.

SCHOOL CLINICS FOR LIVERPOOL.

LIVERPOOL has been slow in making adequate arrangements for the treatment of its school children found on inspection to be suffering from medical defects. Other great cities have had organized clinics in existence for several years, and the advantage to the children and the work of education has been proved beyond dispute. The Liverpool venture is of no great magnitude, certainly not when the greatness of the city, the number of its school children, and the area of its poor quarters are taken into consideration. The venture is to consist in the establishment of a clinic for the treatment of enlarged tonsils and adenoids. It is proposed to provide for the necessities of 800 to 1,000 cases in each year at a cost of £995. Truly it is not a great scheme for so great a city; there is no provision for the teeth, or eyes, or the several minor ailments that ruin school attendance and reduce the Government education grant, and incidentally make school work somewhat of a purgatory to the little ones. But, may be, this is only a beginning, a foreshadowing of a more ample scheme, and as such the local profession will welcome it. The time has gone when children judged to fail of the physical standard rightly set up by the school doctors should be expected to plead for charitable medical attendance; the community, through the voice of Parliament, has clearly made it the duty of local authorities to consider and meet such necessities, and no local authority which has undertaken this duty has found cause to do other than congratulate itself on the results.

It has been suggested that benevolent societies be formed for the benefit of the families of officers and other ranks of the medical services auxiliary to the Regular Royal Army Medical Corps—namely, the Special Reserve, the Territorial Force, and new army. Funds would be raised by voluntary subscriptions, and it has been proposed that each branch of the service should appoint a committee of five to seven members to administer its own funds. A meeting, presided over by the Director-General, will be held in the Lecture Theatre of the Royal Army Medical College, Grosvenor Road, S.W., on Wednesday, May 10th, at 3 p.m., and it is hoped that as many officers as possible will attend. In the meantime any inquiries may be referred to Lieutenant-Colonel G. St. C. Thom, R.A.M.C., War Office, S.W.

A COMMITTEE, among the members of which are Dr. L. B. Aldrich-Blake, Dean of the London School of Medicine for Women, and Mrs. Henry Fawcett, has been formed to raise a fund for a memorial to the late Dr. Mary Murdoch of Hull, an obituary of whom was published in the *BRITISH MEDICAL JOURNAL* of April 1st. It is proposed that the memorial shall take the form of a bursary or bursaries in connexion with the school, to be applied for the assistance of young women in their first years of practice. Subscriptions should be sent to the honorary treasurer, the Hon. Mrs. Franklin, 50, Porchester Terrace, London, W.

¹ *Journ. Experim. Med.*, Baltimore, 1916, xxiii, 443.

Medical Notes in Parliament.

War.

Pulmonary Tuberculosis.—Major Astor asked, on April 19th, the grounds on which the Army Council had decided that a soldier must be discharged from the army directly it was determined that he was suffering from pulmonary tuberculosis, and without giving him any period of treatment, such as was given in the case of all other diseases. Mr. Tennant replied that it was considered that a man suffering from pulmonary tuberculosis was unfit to serve as a soldier. It was essential that these cases should be specially treated in a sanatorium at as early a date as possible. Arrangements had been made, in the man's own interest, with the Insurance Commissioners and the Local Government Board, so that a soldier found to be suffering from tubercle of the lung should be discharged the service at once and admitted to a sanatorium. Discharge took place under paragraph 399 of the King's Regulations. Mr. Tennant was pressed on the point by various members, who alleged that there was no sanatorium accommodation available either for soldiers or civilians who live in the London district; and, further, that there was difficulty in getting men to go to sanatoriums owing to the fact that no separation allowance was granted if they went. Mr. Tennant agreed that men discharged from the army would get no separation allowance, but promised to have the whole matter of their being given treatment before discharge looked into. On April 25th Mr. Glyn-Jones asked how many men had been discharged from the army and navy during the past year suffering from tuberculosis, and in what proportion of such cases had the Insurance Commissioners been able to provide immediate accommodation in sanatoriums. The Chairman of the Joint Committee of Insurance Commissioners said that the first part of the question should be addressed to the War Office and Admiralty. As to the second part, he said that since the special arrangements for the immediate residential treatment for discharged tuberculous soldiers and sailors came into force—in April and August, 1915, respectively—approximately 2,450 cases had been reported to the several Commissions by the War Office and Admiralty as cases in which residential treatment was essential, and he was not aware of any such case in which accommodation had not immediately been made available.

Medical Examination Fees.—On April 19th Mr. Joynson-Hicks asked the Under Secretary of State for War whether he was aware that a number of doctors were appointed by recruiting officers in the early period of the war to examine recruits at a fee of 2s. 6d. a head; whether such fees were from time to time paid; whether he was aware that many doctors, during the period of rush in December, 1915, gave up their private practice, and, with the help of assistants working twelve to fifteen hours a day, examined and passed a number of recruits, but had been refused payment of anything more than £2 per day, representing sixteen recruits; and whether he would cause an inquiry to be held into the matter. The Financial Secretary to the War Office (Mr. Forster) said that the ordinary fee was 2s. 6d. per recruit examined, and this regulation was in force at the beginning of the war. But in February, 1915, it was modified to the effect that where considerable numbers were examined £2 should be the maximum for a full day's work.

Steel Helmets.—In reply to Mr. Percy Harris (Market Harborough), who asked whether the steel helmet issued to the troops weighed 32 oz. and was not ventilated, and whether there was in existence a pattern helmet, properly ventilated, and only weighing 16 oz., Dr. Addison said, on April 19th, that the service steel helmet weighed 32 oz., and improved internal fittings which would improve the ventilation and render the helmet more comfortable were now being made. The helmet had given great satisfaction and had saved many casualties; it was not proposed to alter the pattern. He knew of no helmet weighing 16 oz. that possessed equal resisting properties. In reply to another question, he said that experience had shown

that the smooth dome of the helmet might reflect the light to some extent in bright or wet weather, and steps were being taken to remedy this defect, not by the provision of covers, but by an alteration in the helmet itself. In reply to other questions, Mr. Tennant confessed himself unable to state the date at which the steel helmets would all have been supplied. Light soft caps had been ordered for issue to men who, in the trenches, were provided with steel helmets. Steel helmets had not been supplied to the forces in Mesopotamia, as it was understood that they were not suitable for use in that climate.

Compulsory Service.—The official report of the proceedings of the secret session of the House of Commons on Tuesday, April 25th, states that the Government, recognizing that the necessary numbers required for the discharge of our military obligations will not be available for service by the time required under the present arrangements, agreed that an immediate effort should be made to obtain the men required by voluntary enlistment from among the unattested married men, and that if at the end of four weeks ending May 27th 50,000 of these have not been secured by direct enlistment, the Government would forthwith ask Parliament for compulsory powers; that if in any week after May 27th, 15,000 were not secured by direct enlistment the same course would be taken, and that these arrangements would hold good until 200,000 unattested men had been obtained. A special committee has been appointed to consider a scheme for meeting cases of hardship arising out of civil liabilities, applicable to all who joined since August 4th, 1914, or who might hereafter join, and to single as well as to married men. The items in respect of which assistance will be granted include rent (including ground rent and rent of business premises), mortgage interest, payments in instalments in virtue of contracts such as purchase of premises, business, or furniture, taxes, rates, insurance premiums, and school fees. It is not contemplated that the assistance granted in any individual case shall exceed £104 a year.

Hours of Work in Munition Factories.—In reply to questions on April 18th Dr. Addison said that the number of hours of work of women or young persons engaged in the manufacture of munitions, as of all women or young persons employed in factories or workshops, was governed by the Factory Acts and orders made thereunder. The ordinary limit of hours in the Factory Acts was sixty a week, but this limit might be extended by general or special orders of exemption, and the Home Secretary had found it necessary, in consultation with the other departments concerned, to make such orders in certain cases. The maximum hours of work permitted for women and young persons on the two-shift system in munition works had hitherto been ten and a half a day and sixty-three a week. The actual hours worked had varied in particular cases, and in a very large number had fallen considerably short of this maximum. Under the new general order now under consideration by the Ministry of Munitions and the Home Office it was contemplated that the maximum allowed should be sixty hours a week. In every case in which night work was sanctioned for women or young persons the firm was required, as a condition of the order, to provide proper messing facilities to the satisfaction of the factory inspector. Further, the Canteens Committee, wherever a need was shown to exist, took active steps to deal with the matter. In a written answer to another question on the same day the Home Secretary also referred to the new general order mentioned by Dr. Addison, and pointed out that the existing order did not, as seemed to be supposed, allow seven and a half hours overtime a week for girls or for boys under 16. In the case of women, it permitted it only for those employed on certain specific classes of work of an exceptionally urgent character.

Infantile Mortality.—The President of the Local Government Board has, in a written answer, given the following statistics of the number of deaths of infants under one year of age in England and Wales for the periods referred to:

Six months ended March 31st, 1913	47,274
" " " 1914	48,965
" " " 1915	50,219
" " " 1916	41,971

Income Tax.—In a written answer to Sir J. D. Rees, the Chancellor of the Exchequer has stated that the exemption as to increases in income tax granted in 1915-16 to officers of the navy and army whose incomes did not exceed £300 a year, and the exemption granted in 1916-17 to all officers, without exception, do not apply to the widows of such of those officers as were killed in action or lost their lives in connexion with the war.

THE WAR.

PERSONAL HYGIENE.

Baths.

At a meeting of the Third Corps Medical Society held on January 15th, 1916, with Colonel B. M. Skinner in the chair, Lieutenant (temporary) A. Cowe, R.A.M.C., read a paper on Divisional Baths. They had, he said, largely been established in disused factories and a proper staff appointed, as far as was possible. Thus in one instance a disused starch factory was made half into a bathroom and half into a laundry. Existing tanks or vats were used; a steam heating apparatus was arranged for each vat which was of sufficient capacity to hold from fifteen to twenty men at a time; they served solely as "soakage vats," and no soap was allowed. There were in addition two large shallow baths, in which the men would wash themselves all over first, using paraffin soap, and then jump into the deeper ones. The water in the shallow baths was changed after each party, while that in the deep vats was removed and replaced about three or four times daily. The shallow baths, Lieutenant Cowe observed, took ten minutes to fill, the deep vats an hour and a half. Parties of ninety men went through undressing, bestowal of clothes and valuables in a cloak-room, bathing and dressing, half-hourly. Subjects with skin diseases were treated separately. In the meantime a staff of women were at work in the laundry department, ironing with hot irons the tunic and trousers, dusting sulphur into the seams and smearing them; in bad cases, with the mercury pomade after ironing. Caps and puttees were sprayed in the cloak-room with 5 per cent. formalin. Dirty underclothing was put direct into a 3 per cent. cresol solution for two hours, then removed to the laundry and boiled in a cauldron in a 1 per cent. solution of the same compound for another two hours, when the laundress scrubbed them on a hard board, using a compound of crude paraffin 5½ pints, water half a pint, and soft soap 3 lb. The clothes were then hung in a large drying room, and dispatched thence to a mending room, where, if vermin were detected, they were soaked for twenty-four hours in a 1 in 1,000 solution of mercury perchloride and washed again. In the mending room as much of the old material as possible was used. About 15 per cent. unfit for reissue, had to be made good by new clothes. After the still wearable underclothing was mended it was ironed, folded, and put up into bundles of ten for reissue.

Lieutenant Bramwell, R.A.M.C., said that the men should bring their blankets for sterilization. Major Puddicombe said that packs should be inspected before bathing parade, as men often changed their shirts before going to the baths so as to obtain a new garment in place of a discarded ragged one. Major E. Alderson recommended trichlorethane made up into soap for killing pediculi. One part of petrol in four of vaseline was also efficient.

Lice.

Captain N. A. Dore, R.A.M.C.(T.F.), read a paper on this subject. Infection of the troops with lice had reached high proportions, mainly because at the outbreak of the war many reservists who joined the Expeditionary Force were infected with *Pediculus vestimentis*. The female, he said, was extremely prolific, producing 8,000 young in its natural life of six weeks; it was also very tenacious of life. The ova, when they were deposited in the seams and folds of the clothing, were so resistant that "sterilized" clothing would yield young adults for a week after treatment. The German method for its extermination, which would not destroy the ova and was thus only satisfactory for the adult, was fumigation with 2 lb. of sulphur to a thousand cubic feet. Camphor and pyrethrum powder were good deterrents, hung in muslin bags round the neck. The best preventive measure was the avoidance of damp straw or hay in billets. The men should be supplied with palliasses which kept the straw dry. In his division, Captain Dore said, wooden platforms were made, raised about a foot from the ground, sacking or canvas being stretched across them so that the men could dispense with straw altogether, and sleep entirely off contact with the ground. Billets were washed with chloride of lime. Reinfection had been much reduced by this means.

Speaking of destructive agents, Captain Dore said that a 7.5 per cent. solution of formaldehyde applied with a Mackenzie's sprayer destroyed adults; about 25,000 blankets were treated monthly by this method, and decrease in pediculi as well as scabies had been noted in the division. The best destructive agent for the ova was to smear a two to one solution of ammoniated mercury in soft soap on the clothes, a hot iron being passed up and down the seams. Petrol and paraffin were destructive, but had objectionable qualities, causing great skin irritation in some subjects. A dusting powder of ammoniated mercury, zinc oxide, and magnesium silicate was highly effective. A powder of naphthalin 96 per cent., iodoform 2 per cent., and creosote 2 per cent. was the very best disinfectant of blankets, but there was a shortage of naphthalin. Steam disinfection of clothing and blankets by the Thresh disinfectant was efficient, but only 600 blankets daily could be disinfected, even in the new double cylinder Foden Lorry Thresh.

During the occupation of Gallipoli an Anzac Medical Association was formed, and held its first meeting at No. 1 Australian Casualty Clearing Station on November 7th, with Colonel N. R. Howse, V.C., C.B. (D.D.M.S.), in the chair. The first subject discussed was the lessening of the incidence of infestation by the clothes louse. Major Butler, D.S.O., enumerated the following as the most practical methods at disposal for dealing with the pest, as many combinations as possible being used:

1. Steam sterilization of clothes and blankets.
2. Deposition under the seams of the clothing of some substance, as vermijell or a mixture of soft soap and crude oil or the use of some mineral oil—for example, kerosene, petrol, etc.
3. The use of N.C.I. powder (2 per cent. iodoform, 2 per cent. creosote, and 96 per cent. naphthalene).
4. The use of "Keating's" or other insect powders, or a bag of sulphur worn round the neck.
5. Mercurial ointment on strands of wool worn round the neck, waist, and calves of legs.
6. Hot ironing the seams of the clothing.
7. Individual search and picking of all clothing.
8. Regular changing of clothes once a week.
9. Regular bathing and general personal cleanliness.
10. The use of an emulsion of ¼ per cent. lysol and 20 per cent. soft soap, to be lathered on the skin and allowed to dry.
11. The cleaning and sterilization or fumigation of blankets and dug-outs—for example, by sulphur dioxide.
12. The immediate destruction by burning of all discarded clothes, etc.

Captain Phipson (6th Gurkhas) said that it was not the fact that the louse always anchored itself to clothing before feeding, and added that while feeding it excreted a substance attractive to flies. This, he thought, might be a factor in the spread of some diseases. Lieutenant-Colonel Fremantle said that in lieu of steam disinfection for blankets he had tried steeping them in cresol (1 in 20) for twenty-four hours, then drying in the sun and storing for two to four weeks before use, so that if any ova had escaped alive and hatched out later the larvae would die from inanition. Major Battye, I.M.S., said that sulphur dioxide properly used killed both lice and nits. Lieutenant-Colonel Dudgeon recommended the Serbian barrels for disinfection by steam as being cheap, effective, and easily installed and run. Solar oil (kerosene without benzine) was much used along the Suez Canal for rubbing into the seams of the clothes; failing this, kerosene was good.

THE BELGIAN FIELD HOSPITAL.

Dr. E. C. THOMPSON, of Omagh, who has been acting as commandant of the Belgian Field Hospital, has sent us an account of his experiences. The hospital has been maintained by the Belgian Field Hospital Committee, but is now about to be taken over by the Belgian military authorities. The post of commandant, which had become vacant, was offered by the chairman, Lord Sydenham, to Dr. Thompson, who writes:

The post at Hoogshatte suited me very well because it was a field hospital; it was located behind the third line of Belgian reserve trenches, and was close down to the firing line at the front in Flanders. Hitherto the commandant had been a civilian and had had no experience of surgical necessities or the management of a large institution, and the consequence was that the hospital organization was not up to date, and there was a good deal of looseness in administration and wasteful expenditure. There was also some friction between the Belgian

and British surgeons; all these matters were soon arranged. The hospital was served by nurses who were all British from home or overseas. I never came across any hospital with a more devoted body of sisters or able nursing staff. They were all thoroughly experienced and well taught, and had been carefully selected before leaving England. The chief surgeon was Major Williams, Professor of Surgery in the University of Ghent, a first-class operator and a surgeon of European reputation. Associated with him were two Belgian assistant surgeons, both able young men, two surgical dressers, and a radiographer. The British staff consisted of the commandant whose duties were chiefly administrative, the commandant's secretary, and two surgeons, one of whom was an American, a very able and experienced surgeon, and the other from St. Bartholomew's Hospital, also a well known and distinguished specialist and a captain R.A.M.C.(T.). The hospital, for administrative purposes, was located in a large convent situated a short distance off the main road leading from Furnes to Ypres, and had four pavilions, or barracks as they are called by the Belgians. It could house about 140 patients, and in case of a serious demand might be enlarged without trouble to a capacity of 200 beds. The hospital has had a chequered but very noble career. It was founded in October, 1914, and was first located in a fine building in Antwerp. After six weeks' very useful work there it was badly shelled, and had to be evacuated. Such was the devotion of the doctors and sisters that they were able to leave the tortured city and retreat safely with all their patients to Furnes, where the hospital was again started in a monastery, and did splendid work during the severe fighting of April, 1915, thousands of very badly wounded being housed, treated, and sent on, when able to be removed, to a base hospital. Unfortunately the hospital came under severe shell fire again, and one of the devoted sisters lost her life from injury by a shell; in consequence the hospital had to be again evacuated. This was successfully accomplished towards the close of April, and a portion of a large convent before referred to was secured for it by the Belgian Government. From this time until now the hospital has carried on its admirable work under the very able guidance of Major Williams and his associated surgeons, both Belgian and British.

There is no hospital at the front better located for the reception of wounded soldiers or placed closer to the firing line. I had a very pleasant time while at the hospital, and was greatly helped in every way by every member of a most capable, plucky, and energetic staff. I saw a great deal of the work of the Royal Army Medical Corps both at the base hospitals at Boulogne and in some of the field hospitals and dressing stations close to where the Belgian Hospital was situated. I cannot speak too highly of the splendid and thorough organization of the R.A.M.C. or of the pluck and energy of every officer with whom I came in contact. I saw the officers at work under heavy shell fire both in dug-out and dressing stations, and they were always plucky and unconcerned. The administration of the corps, in every particular, under the very capable control of Sir A. Sloggett and his assistants, could not possibly be excelled. Everything was well thought out, supplies were plentiful, and every officer and soldier I met—and they were many—was loud in his praises of the skill, attention, and devotion of both the officers and men of this grand army department. If other departments of the army were unorganized and tardy in expanding to the necessary requirements of a large army this cannot be said of the R.A.M.C., which in previous years had been thoroughly reorganized under the able supervision of Sir Alfred Keogh, the present Director-General of the Army Medical Corps at home, who, when previously in office, had rendered his country such splendid services both in the South African war and afterwards in preparing for what all soldiers anticipated for years previous to 1914—namely, the present terrible world-war. It has been said by some people (politicians, I believe) that the Director-General should control the R.A.M.C. both at home and in France. The idea is nonsense. The present arrangement is the only possible one, and it is carried on most thoroughly and efficiently and without any friction, because the two Director-Generals are most suitable and practical men, devoted to the service and with a single eye to do their utmost for the good of their own corps, of which they are such efficient and experienced chiefs, and of the soldiers of the British army, in whose interests they have left nothing undone to lessen suffering or to help to restore them again to the blessings of health and strength. When the history of the war comes to be written one department at least, namely, the R.A.M.C., will shine forth triumphant.

When I left Belgium, after more than five months' service there, the Belgian Field Hospital had been thoroughly reorganized and was working in every department with efficiency and success.

LAND MINE WOUNDS.

In the fighting between the Italians and the Austrians among the mountain passes much use is made of the land mine or torpedo, which is carefully concealed somewhere in a narrow mountain track. As used by the Austrians this mine consists of a wooden or tin box, packed with explosives and iron nails, and connected with a fuse and wire in which the unwary enemy catches his foot, firing the mine. During seven months' service in the Southern Tyrol, Dr. P. R. von Walzel¹ observed thirteen casualties inflicted by this weapon only a few hours before the patients reached hospital. A characteristic feature was the great variety and number of wounds in each case. The nails, the outer case of the mine, the fuse, splinters of wood and stone, earth and the material used to hide the mine, all left their mark on the unfortunate victim, one side of whose body would be liberally peppered, while the other scarcely showed a scratch. The wounds included bruises of every size, incised wounds of almost every possible variety, and burns of every degree. The wounds were comparable to those inflicted by shell fire, but showed an even greater diversity. Their severity was mainly due to their cumulative effect, and within a few hours of their infliction the general condition of all the patients was very bad. The temperature usually rose early, owing to the great number of abscesses provoked by foreign bodies. The iron constituents of the mine usually penetrated furthest, but sometimes they could be felt under the skin, or seen projecting from the wounds. Owing to the jagged shape of the nails, the wounds were often very irregular and lacerated. Stones, as large as chestnuts, might be found buried just under the skin, and in one case a fragment of stone no larger than a grain of rice was found embedded under the skin of the penis. In the same case a splinter of wood, of the size of a pen, had entered just above the left clavicle, and had passed to the region of the right lower jaw, whence it was removed. On admission to hospital the patients complained of intolerable pain and were most restless. An injection of morphine was given at once, as well as 20 units of antitetanus serum. The wounds were then cleaned with benzene and alcohol, usually under a general anaesthetic (ether). Every visible and palpable foreign body was removed, the frayed edges of the wounds were trimmed, pockets formed by projectiles were opened up and irrigated with hydrogen peroxide, and the injured limbs were raised to reduce oedema. The wounds were dressed with sterile rice-powder and lint. The numerous abscesses which began to develop within twenty-four hours were incised under ethyl chloride spray. With one exception, the patients rapidly recovered.

CASUALTIES IN THE MEDICAL SERVICES.

Wounded.

Captain P. R. Woodhouse, R.A.M.C. (temporary).
Captain H. G. Peake, R.A.M.C. (temporary).
Lieutenant G. L. Kennedy, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Welstead, Harold Wilfrid, Sergeant Canadian Force, third son of Dr. F. Welstead, of Kimbolton House, Alleyn Park, West Dulwich, killed on April 4th, aged 28.

NOTES.

DR. JAMES GALLOWAY, senior physician to Charing Cross Hospital, has been appointed a consulting physician to His Majesty's forces in France with the rank of Colonel A.M.S.

The Society of Old Students of the Val-de-Grâce Military Hospital, Paris, held its general meeting on April 20th. M. Godart, Under Secretary of State, who presided, paid a tribute to the medical service of the French army. He said that since the beginning of the war 571 doctors and pharmacists had been killed in battle or had died of contagious diseases.

Canada.

CANADIAN DEPARTMENT OF PUBLIC HEALTH.

A BRIEF debate recently took place in the House of Commons on the advisability of establishing a Canadian Department of Public Health. Dr. Michael Steele, member for South Perth, in the province of Ontario, in moving that the organization of a department of public health was desirable in order to conserve in the largest measure possible the physical welfare of the people of the Dominion, said that the various branches of public health were at present administered by several separate departments at Ottawa, and urged the advantage of centralization. The establishment of hospitals, charities, and similar matters was in the hands of the provincial governments in accordance with the British North America Act, but by this same Act the question of creating a public health department was left with the Federal Government, which already administered such branches of public health as quarantine, adulteration of foods, and inspection of meat. The Hon. J. D. Hazen, while admitting the advantage of centralizing the branches of public health work already in the hands of the Dominion Government, thought that serious consideration should be given to the question before matters now administered by the provincial governments were transferred to the Federal Government. He thought that as the war was the one great problem occupying the attention of the country at present the question of creating a public health department should be adjourned until a more opportune time, and this view prevailed.

ONTARIO MEDICAL ASSOCIATION.

The annual meeting of the Ontario Medical Association will take place this year at Toronto from May 30th to June 2nd, when several matters of great importance to the profession will be considered. Particular interest centres round the Commission on Medical Education, which recently concluded the taking of evidence. The profession maintained in evidence given before it that the practice of medicine should be limited to those who conformed to the educational requirements of the Ontario College of Physicians and Surgeons and passed the examinations prescribed by that body. It is understood that the report of the Commission will not come before the Legislature during the present session, and it is hoped at the forthcoming meeting of the association to obtain further expression of the views of the profession. Another question of particular interest is the Workmen's Compensation Act, which, in its present form, makes no adequate provision for the payment of the doctor's fee. This point was included in the questions taken up by a deputation representing the Trades and Labour Congress of Canada and the Ontario Labour Educational Association, which waited on the Ontario Government on March 17th last, with the request that the Workmen's Compensation Act should be so amended that hospitals would receive payment for first-aid services out of the funds provided under the Act. The address in medicine will be delivered by Dr. E. P. Joslin, of Boston, on the treatment of diabetes; Dr. DeWit Lewis, of Chicago, will give the address in surgery; and Dr. J. F. Percy, of Galesburg, Illinois, that in gynaecology. A session will be devoted to the problem of the returned soldier, from the medical, military, vocational, and economical standpoints. It is hoped that representatives from the military convalescent hospitals throughout the country will be present, and that it will be possible then to make arrangements for a uniform policy and procedure in such institutions.

FREE ANTITOXIN IN ONTARIO.

The Hon. J. W. Hanna, provincial secretary for the province of Ontario, recently stated that 300,000 soldiers had been inoculated with typhoid antitoxin supplied free of charge by the Ontario Government, and that the regular price of this amount of antitoxin would have been 225,000 dols. The new arrangement whereby various vaccines are also supplied free of charge to municipalities and physicians throughout the province came into force on February 1st last, and during that month, in addition to the typhoid antitoxin, vaccines to the value of 7,000 dols. were supplied free. The provincial Health Act has been amended to provide that any person who sells, publicly or

privately, any of the free vaccines supplied by the Government shall be liable to a fine of 100 dols. or three months' imprisonment.

India.

THE BOMBAY MEDICAL UNION.

At the annual general meeting, on February 26th, of the Bombay Medical Union—a body which consists of Indian medical men in the Bombay Presidency, many of whom also hold European qualifications—the President, Dr. B. S. Shroff, L.M. and S., delivered an address, in the course of which he dealt with three important points. The first was the readiness with which the Indian medical profession came to the aid of Government during the war. In Bombay alone 150 men volunteered for general service. The number of temporary commissions granted was stated to be 166, and of these 32 were given in England. Out of the total perhaps a dozen were Europeans or Eurasians. Dr. Shroff observed that, while all temporary lieutenants in the R.A.M.C. have been promoted to captain on completion of a year's service, those in the I.M.S. have not been thus promoted, and complained of "this invidious distinction in the treatment of Indians," but we understand that the permanent lieutenants in the I.M.S. have not been promoted, so that the disability is one which has affected all officers of the I.M.S., Europeans and Indians alike. The second point was the Bogus Medical Degrees Bill, designed to prevent the assumption and use by unqualified persons of titles implying qualification in Western medical science. Of this bill the President heartily approved, though it had met with much opposition from some educated Indians. As regards the advisability of Government recognition of the Yunani (Muselman) and Ayurvedic (Hindu) systems of medicine, the union, we gather, holds an open mind and reserves its opinion. The third important subject was the proposal to found a second medical college in Bombay. Such a college, the union suggests, might utilize the services of qualified Indians as an honorary staff, as in British hospitals. An independent medical college, it is urged, would enter into healthy rivalry with the Government medical school, and competition would stimulate progress in both institutions.

SANITATION IN BENGAL.

Mr. G. B. Williams, the Sanitary Engineer to the Government of Bengal and President of the local section of the Institution of Mechanical Engineers, has published, for the use of those who contemplate entering the new local service of municipal sanitary engineers, an excellent manual of the various branches of engineering which will come within their ken. It is replete with practical illustrations derived from a wide experience of conditions in Bengal. Discussing building construction, for example, Mr. Williams is not content with a few jejune rules as to desirable elevation, stability of foundations, etc. He assumes that the Indian sanitary inspector, in this sphere, as in others, will desire to exercise an improving influence. There is probably no country in the world, he observes, where a dissemination of the elementary principles of building construction is more desirable, and he adds: "It would, at all events, be hard to discover one where they are more consistently and universally disregarded. In respect of the choice of situation, the materials used, the design of the buildings, and the manner in which they are erected, it would be difficult to find anything much worse than many of the dwelling houses which disfigure the Indian towns and villages."

COCAINE IN CALCUTTA.

The evil progress of the drug habit in India is illustrated by some unpleasant particulars given in a lecture at the University Institute in Calcutta by Captain W. J. Clifford. He said the drug habit in Calcutta had great centres at Taltola and Chitpore. The two principal drugs used were, he said, opium and cocaine. It was usually found that opium was taken by Chinese and Obriahs, and cocaine by young lads. Captain Clifford appealed to those present not to leave all the action to societies, but to study the problems themselves, and make personal efforts to help. Captain Clifford said he had

spent ten years in social work in Calcutta, and on looking back over that period felt bound to come to the conclusion that both drinking and the drug habit were on the increase. Cocaine used to reach India from Germany and Austria.

ST. JOHN AMBULANCE AND RED CROSS WORK.

It has been announced that Sir C. P. Lukis, K.C.S.I., K.H.S., V.D., Director-General of the Indian Medical Service, and Chairman of the Executive Committee of the Indian Council, St. John Ambulance Association, has been appointed Commissioner for the St. John Ambulance Brigade Overseas within the empire of India. It is announced, further, that Lieutenant-Colonel Jay Gould, Indian Medical Service, is to proceed to Mesopotamia for duty in connexion with the formation of an advanced medical stores dépôt, and as the Red Cross representative of the Indian Council of the St. John Ambulance Association. Lieutenant-Colonel Swinton, Medical Storekeeper to Government, Calcutta, will succeed Lieutenant-Colonel Jay Gould as Deputy Director-General of the Indian Medical Service.

THE LADY HARDINGE MEDICAL COLLEGE.

In response to the appeal made by His Excellency the Viceroy at the opening on February 17th for further funds for the Lady Hardinge Medical College, the following generous donations have already been received: His Highness the Maharajah of Gwalior, Rs. 50,000; Her Highness the Begum of Bhopal, Rs. 20,000; and His Highness the Maharajah of Bikaner, Rs. 12,000.

MEDICAL INSPECTION OF SCHOOLS IN MADRAS.

The Madras Government has approved of the proposal of the Surgeon-General to entrust the work of supervising the medical inspection of schools opened by the corporation of Madras to Lieutenant-Colonel C. Donovan, I.M.S., and the payment to that officer of an honorarium of Rs. 200. The Director of Public Instruction has been requested to submit a copy of the report of the inspection, with such remarks as he may have to offer on the success of the experiment and on the question of extending the inspection to other educational institutions. The scheme for the inspection of schools for Europeans in the city of Madras will be allowed to lie over, pending the receipt and consideration of that report.

HOSPITALS IN INDIA.

In the course of an interesting address delivered on the occasion of the opening of a hospital at Tinnevely, Surgeon-General Bannerman explained the origin of hospitals in India and their development. He said that in the very old days of the Emperor Asoka there were a few hospitals under his auspices, but with the overthrow of his kingdom the hospitals disappeared from that time until the advent of the English. There were no hospitals at all when the English arrived and began to maintain soldiers and an army. A hospital to treat soldiers was built in Madras in 1664, and was the first institution of its kind in India. As hospitals for soldiers multiplied in the cantonments of India, the civil population also wished to avail itself of the treatment accorded therein, and the nucleus of the Madras General Hospital was built in 1772. Since then hospitals had spread throughout the length and breadth of the Presidency and of India. They arose out of the charity of the people, and he appealed to Indians to send the stream of their charity in this direction.

Ireland.

THE Irish Medical Secretary of the British Medical Association has addressed a letter to the Chief Secretary for Ireland drawing his attention to the increased motor taxes and their effect on medical practitioners. Mr. Birrell replied that the existing concession under which registered medical practitioners pay only half rates will extend to the new duties, and with regard to the inequality in the burden of taxation on the owners of old and of modern motor cars,

stated that this and all other relevant questions relating to the proposed increases in motor car licence duties would be considered before the Finance Bill dealing with this matter was introduced.

Further leave of absence for twelve months has been granted to Captain G. H. Russell, R.A.M.C., by the Committee of Management of the County Tipperary Infirmary, of which he was in charge before the war.

The Local Government Board has objected to the Rath-down board of guardians paying remuneration at the rate of four guineas a week to the locumtenent for Dr. Roan-tree, who has accepted a commission in the R.A.M.C. The Board considers that in all cases of prolonged temporary employment, the fixed salary of the officer, and not the fee (four guineas a week) for a short period, should be paid. The clerk stated that the difference between the two allowances was £73 8s. a year, and the guardians decided to communicate again with the Local Government Board.

Correspondence.

TIME IN SURGERY.

SIR,—In the midst of so much that engages our attention in connexion with the war it was refreshing in the issue of the JOURNAL of April 15th, p. 549, to have attention diverted to a practical subject in general surgery so cogent in its bearings on successful treatment as that contained in a short article by Mr. Rowlands on "Time in Surgery." It is with the hope of still further drawing attention to the great significance of such a factor in our work that I am tempted, with whatever weight I may possess, to endorse the sentiments so well and clearly expressed and advocated by him.

It is more particularly in connexion with abdominal surgery that I would emphasize adequacy in diagnosis and rapidity in operating. It is, I think, from America that the very pertinent saying emanated, "Get in as soon as possible and out as quickly as you can." No one who has taken the trouble to contrast the results of his abdominal work can have failed to note how marked is the difference in the after-effects upon a patient the interior of whose abdomen has received but a short exposure, and on one in whom such exposure has been prolonged. So impressive is the result that if only boldness and rapidity be adequately coupled with discretion and precaution the surgeon may be ready to endure the taunt of having "one eye on the clock and the other on the patient," a reflection, however, which, when cast, is usually the expression of ignorance and inexperience. Unfortunately, I cannot recall the actual time the operation took; but it is so essential a part of my practice to complete every "abdominal" well under the hour, that I know the case did not nearly extend to that period. But I give it as an example, because although some years have now elapsed since its occurrence, it impressed me at the time and served as a source of encouragement to me in my subsequent work. I had performed a partial gastrectomy for gastric carcinoma. The next morning on visiting my patient I found him reading the morning paper; he had had a comfortable night and felt quite well. Indeed, for all that he suffered, I might have done nothing more than have washed out his stomach on the previous day. Such results cannot possibly be obtained where an operation has necessitated the prolonged administration of an anaesthetic and entailed an amount of shock consequent on lengthy exposure and manipulation of the abdominal viscera.

Mr. Rowlands's three recommendations to ensure rapidity of operation are so tersely and clearly expressed that I should like to be allowed to conclude my letter by repeating them, for they not only constitute the essential requisites for the patient's immediate comfort and welfare, but they render more certain the surgeon's success.

1. By making all possible preparations and calculations beforehand.
2. By improving and simplifying the technique of the operation in every possible way.
3. By concentrating the full attention upon the operation.

—I am, etc.,

Glasgow, April 17th.

A. ERNEST MAYLARD.

JEJUNOSTOMY AND JEJUNO COLOSTOMY.

SIR.—Mr. Victor Bonney's achievement in saving by jejunostomy the lives of six patients with obstruction from pelvic or general peritonitis demands, and will receive, general recognition.

Yet the treatment by jejunostomy, however successful, is in my opinion far from ideal. Mr. Bonney says, in his letter of April 11th:

Mr. Handley suggests jejuno-colostomy and caecostomy, which is in effect a jejunostomy, with the difference that the drainage from the jejunum takes a course through a segment of the large intestine instead of reaching the exterior direct.

In reply to this let me quote Mr. Bonney himself (BRITISH MEDICAL JOURNAL, April 22nd, 1916) on jejunostomy:

At the end of a week or ten days closure of the jejunal opening has to be undertaken. As by this time the skin is very red and excoriated around the opening, the preparation of the operation area should be limited to the application of iodine solution on the table. It is no use attempting a paring operation: the whole opening must be removed, the bowel sutured end to end, and the abdominal wound separately closed.

In contrast to this severe procedure, a caecostomy will usually close spontaneously. Moreover, jejunostomy is an unphysiological operation, which is not consistent with the indefinite prolongation of life. It impairs the patient's nutrition, and must therefore lessen his resisting power, and in really severe infections his chance of recovery. I have not been able to verify Mr. Bonney's three zones of intestine: (a) A collapsed portion; (b) a portion above it much distended by gas but containing no fluid matter; (c) a portion above that, distended with gas and fluid matter, which must be drained by a jejunostomy. What I have observed is paralysis of the intestines, usually accompanied by collapse, up to a varying horizontal level in the abdomen. Above this level the small intestine is distended but not paralysed, and here, as I have shown, a physiologically complete and functionally active intestinal canal can be improvised.

I have compared this policy to that strategic retirement upwards to the first floor which is necessary when a house is invaded by a flood. I would compare Mr. Bonney's policy of jejunostomy to a retreat to the roof, involving unnecessary discomfort and bringing dangers of its own.—I am etc.,

London, W., April 24th.

W. SAMPSON HANDLEY.

THE INCREASED MOTOR LICENCES.

SIR.—May I be allowed, on behalf of the very large number of medical owners of Ford cars, briefly to criticize the article by Mr. H. Massac Buist in your issue of April 15th, 1916? He recognizes, as must every one, that the new motor taxes are so arranged that Ford owners will stand in a class apart. They will pay an annual tax of 18 guineas on a car which cost them (in all cases except the few which have been bought since the importation duties increased the price) from £115 to £125.

When this is compared with the tax paid by the owner of the average English car, say a Sunbeam or a Vulcan, who will pay only 8 guineas on a car which costs £400 to £500, the difference is so startling that Mr. Buist feels bound to offer some explanation. As all such imports are now stopped, it cannot be said that the intention is to prevent the public from buying American cars; it is only the present owners who are sacrificed, so the explanation offered is that the new tax will assist the mechanical development of the motor. The old "long-stroke *versus* short-stroke" controversy is raked up; but let us look the facts in the face. The Ford car is cheaper to buy, and cheaper to run, than any English car of similar size, power, and degree of comfort. Why? Not because the American has stuck to the same relatively large bore all the time, and twiddled his thumbs, as Mr. Buist implies; but because he has found that with the short-stroke, low-compression engine, though theoretically less efficient, there is so much less stress upon the parts of the engine and chassis that it is possible to turn out a car with much lighter parts than with the long-stroke, high-compression engine.

So much so, that the slight theoretical relative inefficiency is much more than compensated by the lightness

of the car both in transmission and framework. This also makes for cheapness of manufacture, which is assisted by standardization, a word which is not yet in the vocabulary of the English maker. To mention a few of the chief reasons why Fords are so much cheaper to run: They are (1) economical of petrol, because they are so light that the slightly less efficient engine is rarely working at more than a quarter throttle; (2) economical of tyres, for the same reason, and also because the lower compression gives less "kick"; (3) economical of oil, because of the efficient yet cheap oiling system; (4) immensely more economical in repairs, because of the standardization and accessibility of parts, which ensure that any part can be replaced easily, at a moment's notice, anywhere. Furthermore, Mr. Buist states that Americans are beginning to copy from us the long-stroke motor. This is merely a question of the adoption or rejection of a principle of debatable value, which has been recognized from the beginnings of motor engineering—for example, the original Ford model had a long-stroke (horizontally-opposed) engine. But when he says that "this type of motor has contributed nothing to the world's knowledge," etc., he is, in my opinion, mistaken, for if any type has been a pioneer this one has. Its system of detachable cylinder-head and crank-chamber base, of transmission, of suspension, of steering, of ignition, of lubrication, are every one original, and have many of them since been copied by English makers. The Ford owner did not buy his car because he was a fool, but because he wished to get the best value for his money; and it seems hard that he should now have to pay so very much more than his share of the motor taxes just because he exercised his common sense and powers of observation.

In conclusion, I think I shall be fairly representing the medical Ford owners when I say that we do not object to the tax because of its size. We only pay half what the layman pays, and in any case it all goes towards killing Germans. But we do object to having to pay more than twice as much tax as another man who could afford to buy a car which cost four times as much as ours.—I am, etc.,

York, April 15th.

J. C. LYTH, M.B.

SIR.—Mr. Massac Buist says Mr. McKenna is treating the profession with fairness and understanding! If so, why should a doctor have to pay nine guineas tax on a Ford car whilst tradesmen, poultry and rabbit merchants, etc., drive Ford cars and lorries and pay no tax? Surely "utility" motor vehicles should bear the burden of taxation as well as the unfortunate medical man.—I am, etc.,

North Molton, April 19th.

F. C. J. BAKER.

SIR.—I think Mr. Massac Buist's article on motor cars for medical men should not be allowed to pass without comment.

The majority of the profession are not men of large capital, and it is therefore in most cases compulsory to buy the cheapest car that will suit their purpose, hence many like myself own American cars.

It so happens that I am able to make an illustrative comparison. A colleague who had more capital to lay out has

A foreign-made 12 to 14-h.p. car, cost £350; I have a Studebaker 20-h.p. car, cost £200.

In one case £350 goes out of the country, in the other £200 goes out of the country.

Our running expenses are practically the same. His tax was £2 2s., is now £4 4s.; mine was £3 3s., is now £9 9s.

Why should I be penalized for keeping £150 in the country?—I am, etc.,

Epsom, April 25th.

E. C. DANIEL.

DR. HERBERT WILLIAMS, Medical Officer of the Port of London, left estate of the value of £7,363.

THE fourth annual meeting of the American Association of Anaesthetists will be held on June 12th at Detroit, Michigan. Among the communications promised is a report by Dr. George W. Crile of an experimental research into nitrous oxide and ether, with special reference to (a) certain effects on the organs of the body, (b) certain relations to normal sleep and certain relations to infection.

Universities and Colleges.

UNIVERSITY OF GLASGOW.

At the graduation ceremony on April 25th the following were among the degrees conferred:

M.D.—Dagmar Florence Curiel, M.B., Ch.B.
Ch.M.—R. B. Carshaw (with high commendation).

The Bellahouston gold medal for eminent merit in thesis for M.D., and the Struthers gold medal and prize of £20 for research in anatomy has been awarded to Dr. Matthew Young. Mr. Kenneth J. T. Wilson has won the Asher Asher gold medal for laryngology and rhinology.

UNIVERSITY OF DUBLIN.

On Wednesday, April 19th, in the theatre of Trinity College, the degrees of M.B., B.Ch., and B.A.O. were conferred upon:

Eileen G. Gwynn and Millicent Hamilton-Johnstone.

NATIONAL UNIVERSITY OF IRELAND.

The degrees of M.B., B.Ch., and B.A.O. were conferred, on April 19th, upon the following:

J. J. A. O'Connor, J. P. Moran, M. O'Sullivan, A. Ryan, Eileen M. E. Bonchier-Hayes, L. Blake, T. J. Bourke, J. C. Carroll, M. A. Clements, E. P. Coyne, J. Curtin, Annie Doherty, Anne Donley, J. Dwan, D. Hughes, W. M. Morris, P. Murphy, P. O'Connell, D. V. O'Malley, H. E. Owens, J. Jollard.

CONJOINT BOARD IN ENGLAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE, Part I (Chemistry) and Part II (Physics).—D. R. Ainsworth, M. L. Barst, A. H. Bean, H. Beger, W. R. B. Booth, H. L. Bowen, P. C. Brett, H. S. Chadwick, J. W. Chadwick, G. W. Cheater, J. J. Coghlan, R. G. Dansie, H. S. Davies, R. M. Ealand, M. N. Eldin, M. A. K. El Hennawy, R. A. Fanous, J. H. France, W. Gothe, M. Hall, R. R. Hallsall, T. H. J. Hargreaves, S. Hazeldine, D. Hoole, A. R. Jones, P. T. Jones, J. D. Kelson, R. O. Lahmann, M. H. Lichtenstein, R. C. Lightwood, J. E. C. McColl, Elizabeth E. McCulloch, J. A. Mackay-Ross, E. D. Macmillan, O. E. J. McOustra, D. Maximos, H. Nosrat, Madeleine P. Parker, L. P. Phillips, H. C. Powell, E. L. J. Reason, J. J. Redelinghuys, T. R. Rees, B. R. Reynolds, Constance E. M. Ridout, Mary J. Ripley, H. L. Sackett, M. Sidky, S. Snelson, J. Sonenberg-Berson, J. Spira, E. H. Strange, H. J. V. Sutton, J. C. Twomey, J. O. M. Wade, J. G. Walker, A. C. Z. Wijayarathne, T. Williams, S. B. Winnick, C. F. Young.
Part III (Elementary Biology).—C. S. Anderson, H. B. Archer, D. A. R. Aufraque, G. F. Baxter, Ivy C. Beach, A. H. Bean, Margaret G. Best, I. Blain, H. B. Beger, H. B. Bramley, E. Brazao, P. C. Brett, Mary Burfield, K. E. Bury, E. J. J. Buyc, L. E. K. Carroll, J. W. Chadwick, G. W. Cheater, Marion C. V. Clarke, Alice M. Clegg, D. H. Cockell, J. J. Coghlan, G. C. W. Curson, R. G. Dausie, H. S. Davies, T. Draper, H. Dryver, R. G. Flintan, H. B. Flocks, W. F. Gawne, B. Goldfoot, W. Göthe, M. Hall, H. J. Henderson, J. Herbert, D. Hoole, F. J. Janch, H. Jennings, S. G. Jones, T. T. Jones, H. D. Kelf, J. D. Kelson, H. A. C. Kne, Agnes Knowles, F. Kuoyle, G. V. C. Last, M. H. Lichtenstein, R. C. Lightwood, H. D. Llewellyn, J. A. Mackay-Ross, C. C. MacKinnon, O. E. J. McOustra, C. B. Martin, A. E. Mills, J. A. Morton, D. J. O'Meara, L. P. Phillips, H. C. Powell, Mary C. Pridcaux, T. R. Rees, B. R. Reynolds, Constance E. M. Ridout, Mary J. Ripley, W. S. Roberts, Edith M. Rooke, Margaret C. Seace, R. C. Shaw, S. Snelson, E. H. Strange, H. J. V. Sutton, J. G. Taft, T. B. Thomas, N. V. Walsworth, W. Walsham, J. S. White, Cathrine M. Williams, Greta I. Yeoman.
Part IV (Practical Pharmacy).—A. M. Ahmad, A. E. Bendix, I. R. R. Brogen, G. E. Burton, H. A. Chodak, A. B. Dummer, J. R. K. Fenning, G. H. Fitzgerald, P. C. A. Friih, T. H. Gunewardene, N. H. Harrison, S. G. Harrison, W. S. Herman, D. L. Lees, H. S. N. Menko, F. M. Mesely, W. P. Nelson, A. L. Packham, D. F. Pantou, W. H. A. Pratt, J. S. Ranson, C. N. Ratcliffe, J. J. Redelinghuys, Florence M. Rhodes, A. H. Richardson, N. F. Smith, C. H. Terry, W. J. Walters, H. P. Warren, I. G. Williams, S. B. Winnick, G. Winter, S. A. Withers, A. F. Wyatt.

SECOND COLLEGE (Anatomy and Physiology).—Y. Abdel-Messiah, A. Abelson, N. D. Ball, Margarita S. Barfield, J. S. Bernuchwitz, J. A. A. Bouie, O. H. Brown, N. C. Cooper, A. N. M. Davidson, E. S. Davies, F. S. Browe, A. Eidinow, F. K. Escritt, F. A. Evans, P. Faraci, J. E. Fishburn, J. O'F. Fletcher, R. Gainsborough, E. S. Gawne, Nannie Gibson, C. Gill-Carey, P. E. Gorst, L. Handy, H. W. Hill, T. E. E. Hillier, A. B. Isaacs, G. H. Johnson, E. F. Kerby, H. H. Khan, F. W. Lemarchand, P. Lloyd-Williams, D. McClean, J. J. M. Macdonnell, C. Moffatt, J. S. Moore, A. R. Neckles, C. Nickory, A. G. Ord, L. D. Porteous, P. G. Quinton, W. E. Quinton, D. H. Richards, E. Sanders, M. C. Sarkies, H. M. Savery, W. M. Savery, E. A. Sparks, V. A. T. Spang, G. McK. Thomas, J. H. Tighe, B. M. Tonkin, W. S. Tunbridge, J. Eliza de Villiers van der Merwe, E. F. Wheeler, H. E. Williams, R. Wolff.

* Passed in Part I only.

† Passed in Part II only.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

FIRST PROFESSIONAL.—L. S. Clifford, J. L. Courtney, A. E. Dempsey, J. A. Flynn, J. E. Hudson, P. Kelly, T. J. Kerr, C. Kidd, J. F. Lyne, J. J. Lee, W. H. Mosbey, P. J. Osborne, W. P. Reynolds, T. J. Ryan.
SECOND PROFESSIONAL.—M. Barden, J. Cockburn, B. Epstein, S. J. Halpin, B. F. Homan, J. McAleer, B. T. McMahon, R. H. Newman, J. Pousner, J. Power.

THIRD PROFESSIONAL.—J. J. Brennan, S. J. Healy, R. J. Bassett, J. P. Brennan, J. J. Campbell, E. M. Lloyd Dodd, D. J. M. O'Flanagan, L. Finnegan, J. A. Hamilton, F. B. Harrison, J. K. Holland, D. B. McNairy, J. A. McSweeney, B. F. O'Reilly, J. G. Smyth, D. E. Young.
FINAL.—J. F. Coffey, K. Elmes, H. Gerrard, J. Magner, C. A. R. McCay, D. McCormack, J. A. McKinnon, A. J. Neilan, J. P. Pegum, G. C. L. Woodroffe.
* With honours.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—*H. Archer, *E. V. Beaumont, M. J. Byrnes, *E. N. Glover, *E. O. Morrison.
MEDICINE.—M. J. Byrnes, M. Dwyer.
FORENSIC MEDICINE.—J. S. Bhajiwalla, H. N. D. Richards, G. G. Higby, C. Segal, M. B. M. Tweed, L. Zarchi.
MIDWIFERY.—C. P. Barber, T. F. Reason, I. H. Syed.
* Section I. † Section II.

The diploma of the Society was granted to Messrs. E. V. Beaumont, M. J. Byrnes, and E. N. Glover.

Obituary.

WILLIAM ALLAN JAMIESON, M.D., LL.D., F.R.C.P.,

CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN,
EDINBURGH ROYAL INFIRMARY.

DR. ALLAN JAMIESON died at his house in Edinburgh on April 21st after an illness of some months. We are indebted to a colleague for the following admirable account of his life and appreciation of his character.

Allan Jamieson was a son of the manse, his father being minister of the parish of Dregghorn, in Ayrshire. He was born in 1839, and received his early education at Irvine Academy, of which school he was equal Dux in 1856. Fifty-two years later, when he was President of the College of Physicians, he and his fellow Dux renewed their acquaintance. After a few months—not very happy ones—spent as a clerk in an insurance office, he matriculated at the University of Glasgow, where he laid the foundation of that love of Greek and the Grecians which endured all his life. He was an enthusiastic member of the Hellenic Society, and spent some of his leisure after his retirement from the infirmary in visiting and revisiting Greece.

After a couple of years in the arts classes, glowing accounts of Australia from some relatives tempted him to cross the seas, and he began work on a sheep run in Queensland. The life was not congenial to him, but the youth did not like to complain to his father about it. One Sunday afternoon he confided his troubles to a lady relative, and it was on her advice that he wrote home his desire to return and study medicine.

The autumn of 1861 saw him a student at Edinburgh, a little older than most of his fellows, determined to justify his action. He worked hard, and graduated in 1865 as the first man of the year. His first experience in practice was at Preston, where he acted as assistant to a relative for two years. He then migrated to Berwick, where he bought a practice. Here began the friendship with the MacLagan family which was to have such an influence on his career. After nine useful years in Berwick he moved to Edinburgh, and put up his plate in Rutland Street. It was on the advice of Douglas MacLagan and Argyll Robertson that he decided to turn his attention to dermatology. MacLagan taught what dermatology was taught in Edinburgh in those days, and therefore his advice was all the more disinterested. Jamieson took the advice, abandoned his growing practice, and went to Vienna to study his subject under Hebra. On his return he commenced practice as a dermatologist, but for long it was an uphill struggle. Specialists, especially skin specialists, were not popular in those days, and for long he knocked at the doors of the infirmary in vain. He attributed his ultimate success to his having cured a very influential manager of eczema of the legs.

At first he had an out-patient department only, and it was in this that he developed the famous Saturday clinics, which grew so popular with the students that the large Clinical Theatre was often insufficient to hold those who desired to attend. He was a modest man, but he was proud of the fact that he taught dermatology to larger classes than any other English-speaking teacher.

For many years these clinics were his only opportunity of teaching, but his success gradually wore down opposition, and his career was crowned by his appointment as lecturer on dermatology in the university in 1897. He retired from active duty on the infirmary staff in 1906, but till a few months ago, when death had obviously laid its hand on his shoulder, he visited the department regularly once a week to see anything of interest and to give his successors the benefit of his experience, and every now and again a clinic to the students.

He kept up his interest in dermatology to the last, was always on the alert for advances in treatment, and, on his deathbed, was making notes for use in the Critical Summaries he used to write regularly in the *Edinburgh Medical Journal*.

His textbook, published in 1888, was at first very successful and rapidly ran to a fourth edition. The English in which it is written is a pleasure to read and the descriptions of the cases are models, but for some reason it fell out of favour, possibly because it was too big for some readers and too small for others.

He had two recreations—archery and cycling. Born in the year of the Eglinton tournament, he was brought up in a district where archery is endemic, and he won the Kilwinning Papingo in 1858. So devoted was he to archery that he took his bow with him to Australia, and with the same bow his son won the King's Prize in 1904. Jamieson himself won the Queen's Prize on two occasions, and on the breast of his full uniform as Surgeon to the King's Body-Guard for Scotland (The Royal Archers) he wore a star indicating that he had won over fifty prizes in their competitions. Cycling he took to late in life, but he became an enthusiastic tourist and spent many of his holidays cycling in France. Only last summer he might often be seen taking a spin before breakfast.

He took little part in affairs, but he served the usual period of two years as President of the Royal College of Physicians with dignity and acceptance; he was a devoted vestryman in St. John's Episcopal Church, and for the last eight years of his life he was an active governor of Donaldson's Hospital.

He wore the Royal Household Medal (1897), and the Coronation Medal (1911), and was a Knight of Grace of the Order of St. John of Jerusalem, in which Order he took a deep interest, and presented a window for the crypt of the chapel in Clerkenwell.

His personal qualities I, who was closely associated with him for twenty-four years, would sum up in a word. He was a typical Scottish gentleman. May the earth rest lightly on his ashes. N. W.

Dr. R. C. MACLAGAN (Edinburgh) writes: It is more than half a century since I made the personal acquaintance of my distant relation, William Allan Jamieson. He had just returned from Australia, though a less likely man to round up a mob of horses would be somewhat difficult to conceive. But a visit to Australia seeming to him necessary in his father's interests, he carried it out even to the flourishing of a stock whip. He entered himself as a student of medicine at the University of Edinburgh and began his studies with enthusiasm and a whole-hearted determination to make the best of his opportunities, choosing his friends among others—I do not include myself—as much devoted to the same study. I saw a great deal of him at this time, and in our evening walks and week-end talks came to the conclusion that if devotion to his profession meant success, Jamieson was marked out for it. One other live interest we had to which Jamieson was as much addicted as a relaxation as he was to medicine as work—archery. Subsequently he became a member of the Royal Company, and there took more than his fair proportion of prizes, attending also with regularity the national meetings. In the earlier days the centre of attraction was the Kilwinning meeting, at which his attention to detail to make his shooting effective was as evident as in the study of his profession. We attended together the last competition for the Kilwinning Papingo, and I have a clear recollection of Jamieson's appearance topped with the large Scotch bonnet, coloured in rings like a target, the visible token of a Kilwinning archer. When he took up dermatology as a speciality his success was marked, the absence of a genial sick-room manner not being so potent in the consulting-room as at the

bedside. Of strong convictions himself, he was apt to give the dicta of acknowledged authorities more credit than was necessary. For a long period he took daily a fixed quantity of Metchnikoff's preparation of milk, in the firm belief that milk so treated was a much more valuable aid to health than the unsophisticated fluid. He was a determined cyclist and much enjoyed a holiday in not too distant foreign parts, and made frequent excursions to the Continent, where the scenery and the daily record of his cyclometer both received consideration. I must not forget his fondness for the study of Greek, which first found development when a student of the Humanities at Glasgow. He enjoyed reading it, and his liking for it took him more than once to the classic shores of Greece and Troy. He had also a good working acquaintance with French and German. He was a successful man as a result of determination and good ability, and as reliable a friend and medical attendant as any one need wish for.

THOMAS COLCOTT FOX, M.B., F.R.C.P.,

PHYSICIAN FOR DISEASES OF THE SKIN, WESTMINSTER HOSPITAL.

Dr. COLCOTT FOX, who died on April 11th, was a son of Dr. L. O. Fox of Broughton, Hants, where he was born in 1849. He was educated at University College School, London, and at the College, from which he went to Peterhouse, Cambridge, as Natural Science Scholar. After taking his degree in Arts at Cambridge he returned to University College as a student of medicine. He obtained the diploma of M.R.C.S. in 1876 and graduated M.B. at the University of London in the same year. He became M.R.C.P. Lond. in 1883, and was elected a Fellow in 1892.

Dr. Colcott Fox was a younger brother of Tilbury Fox, and this doubtless determined his choice of dermatology as a speciality. After holding for some time the post of medical superintendent of the Fulham Small-pox Hospital, he was appointed physician for diseases of the skin at Westminster Hospital; he was also visiting dermatologist to the ringworm schools of the Metropolitan Asylums Board. He was at one time physician to the Victoria Hospital for Children, to the St. George and St. James's Dispensary, and to the Skin Department of the Paddington Green Children's Hospital. Dr. Colcott Fox collaborated with his brother in an *Epitome of Skin Diseases*, which ran through several editions; he was also the author of numerous contributions to medical literature, mainly on diseases of the skin, published in the *British Journal of Dermatology* and the *Transactions* of various societies.

In 1890 he married Ida Mary, daughter of Mr. J. S. Hay-Newton of Newton Hall, Gifford, N.B. He was disabled by illness while still in the full tide of active professional work, and spent the last years of his life in retirement.

Though perhaps somewhat overshadowed by the fame of his distinguished brother, Colcott Fox won for himself a considerable reputation. He was a recognized authority on ringworm, in the treatment of which he had an exceptionally large experience. His modesty and dislike of publicity, however, stood in the way of his securing any great measure of what is popularly regarded as success. But he achieved something much better and greater by gaining the respect of his professional brethren and the affection of all who knew him.

In his early days Dr. Fox, who was fond of games and sports, played cricket for Hampshire and the Incogniti.

JAMES HARPER, M.D. LOND.,

A.D.M.S. 1ST LONDON DIVISION.

By the death of Dr. James Harper, of 25, Rosary Gardens, S.W., the profession has lost a very able and notable member, and South Kensington one of its most prominent and trusted practitioners.

James Harper was born at Leith in 1857, but his father, a medical practitioner, very shortly afterwards moved to Windsor, where Harper's boyhood was spent. He was educated at Amersham Hall School, Reading, and having matriculated at the University of London, he entered as a student at St. Bartholomew's Hospital. His career there was very successful; from the first he was a marked man, for his great ability and industry were associated with such a robustness of character and also such a merry humour that all who knew him were drawn to him and

were helped by his example. He passed his medical examinations with ease, took honours in Obstetric Medicine at the Final M.B. Examination in 1881, and in 1883 graduated M.D.Lond. He filled the office of house-surgeon at St. Bartholomew's, and afterwards was successively house-physician to the Royal Hospital for Diseases of the Chest and resident medical officer and anaesthetist to the Hospital for Women, Chelsea.

Having thus fitted himself for practice, he took a house in South Kensington, and quickly gathered about him a large practice. His patients highly valued him, for his medical knowledge and experience were combined with such kindness of heart and strong common sense that they found him to be not only a wise medical adviser, but a strong and true friend. The high esteem in which he was held was strikingly shown by the large gathering of mourners who attended the funeral service.

But Harper's activities were not limited by the demands of his practice, and for many years he devoted a good deal of time to the medical corps of the Volunteers. Joining the Volunteer M.S.C. in 1894, he in due course became captain, major, and then lieutenant-colonel in that force. In April, 1908, he was appointed to the 3rd London Field Ambulance, and in 1912 was promoted to the rank of colonel and made A.D.M.S. 1st London Division. He was intensely interested in his military duties, and threw himself into the work of training his ambulance units with great enthusiasm and success. At the outbreak of the war he laid aside his practice and devoted himself wholly to his work as A.D.M.S.; he only gave it up when he was a broken man, too ill to do it. He was secretary of the Army, Navy, and Ambulance Section of the annual meeting of the British Medical Association held at Ipswich in 1900, and Vice-President of the Section in 1910 when it met in London.

Harper was a man of fine presence, and in his physical vigour as well as in his strength of character, tempered by a deeply religious spirit, he showed the influence of his Scottish parentage. About four years ago he underwent a serious operation, and although he recovered and resumed his practice, his work afterwards was often carried out under difficulty. Early this year signs of increasing illness showed themselves, and, in spite of rest and the efforts of trusted and attached medical friends, his weakness increased, and he passed away on March 24th. None who ever knew James Harper will ever forget him. His elevation of character placed him quite above the ordinary run of men. His perfect integrity made him a tower of strength.

Dr. Harper was twice married—first to Miss Helen Watson Brand, daughter of the late Alexander Brand, U.S. Consul, Aberdeen, and later to Miss Annette Ellen Grant, youngest daughter of the late Admiral Henry Duncan Grant, C.B. He left three sons and two daughters; one son was lost in the war, in the explosion of the *Princess Irene*.

COLIN G. CAMPBELL, L.R.C.P.I., M.R.C.S.,

SOUTHPORT.

In less strenuous times the recent death of Dr. Colin Campbell of Southport would have attracted more attention from the members of the British Medical Association, in the welfare of which he always took a warm and often lively interest. He was born in Dublin on April 24th, 1852, and died in Southport on March 10th, 1916. He was thus in the sixty-fourth year of a busy life in which there had been many striking episodes.

He obtained his medical qualifications in 1874, but prior to that he had much medical and surgical experience in the Franco-German war of 1870-71. Like practically every Irishman of that day, his sympathies were with the French, and he put his sympathies into action by joining the Irish ambulance, with which he served throughout the war, and for some time was in charge of a clearing hospital. For his services he received the French Bronze Cross, and was described in his discharge paper as assistant surgeon. He always took an active interest in military matters, and during the Boer war was mainly instrumental in raising a volunteer company in Saddleworth, in which he then practised. In Southport he was one of the founders of the National Reserve, and a short time before his death he was a civil surgeon to the forces in Southport.

He was for some years in practice in Tamworth; in 1882 he went to Saddleworth, where he remained till 1902, and in that year he removed to Southport, where he carried on the treatment of lung diseases until his death. He often obtained marked success in the treatment of respiratory affections by means of medicinal injections through the larynx. He was not widely followed in this method of treatment, possibly because it required an amount of dexterity which very few could acquire. He frequently injected half a pint or more of a preparation of iodo into the lungs at one sitting. He was able to direct this fluid into any part of either lung by means of a chair which he invented, and in which the patient could be suddenly inverted to either side. The writer has not an unpleasant recollection of sitting in the chair when, without the slightest warning from the operator, he found his head pointing to the ground and his lower extremities in the opposite direction. Dr. Colin Campbell's successes in treatment were all the more marked when it is taken into account that nearly all his cases had been failures in the hands of many others.

With the exception of one year he was a member of the British Medical Association from 1878 till his death. He was on the Council of the Lancashire and Cheshire Branch from 1895 to 1898, and represented that Branch on the old Parliamentary Bills Committee from 1899 to 1901, and on the Council of the Association from 1900 to 1903. He was vice-president of the Section of Industrial Hygiene and Diseases of Occupation, 1902.

Colin Campbell was an excellent speaker, and his clear, clean-cut language always commanded attention in any audience. He was a reformer of a moderate type, and when he thought the more active members of that class were carrying the Association beyond the true interests of the profession, he ceased his former interests in the propaganda. He was a great friend and admirer of the late Lord Ilkeston (Sir Walter Foster), and his long and intimate friendship with Mr. Walter Whitehead only terminated with the death of the latter. He was a most genial and warm-hearted man, endowed with a large measure of wit and humour. After some unfortunate experiences at the hands of the dermatologists he wittily described them as superficialists, and his description of Donnybrook Fair was exceedingly humorous.

He leaves a widow, son, and daughter to mourn his loss. The son is in the R.A.M.C. and is at present serving in France.

Colin Campbell will always remain a green spot in the memory of all who knew him.

HENRY COLLEY MARCH, M.D.,

FORMERLY SURGEON TO THE ROCHDALE INFIRMARY.

DR. HENRY COLLEY MARCH, J.P., died at his residence in Portesham, Devonshire, on February 15th, at the age of 78. He was well known in Rochdale, Lancashire, where he had been in practice for over thirty years, but he was compelled to leave that town in 1896 on account of ill health, and to live in a southern part of England, visiting the Pyrenees in winter. His father was the Rev. Henry March, a Congregational minister at Newbury, well known in the south of England. Henry Colley March studied medicine at St. Thomas's Hospital, holding the appointment of resident accoucheur after taking the diplomas of M.R.C.S., L.M., and L.S.A. in 1860. He took honours in anatomy and physiology in the first M.B. examination of the University of London in the same year, and received the degree of M.D. in 1867. After holding a resident appointment at Reading Dispensary, Dr. March went to Rochdale, where his brother had been in practice as a solicitor since 1852. Dr. March became surgeon to the Rochdale Infirmary and soon acquired an extensive practice. At the same time he took an active share in scientific investigations, being among the earliest authorities who undertook in earnest the investigation of the archaeology and geology of the Rochdale hills. Dr. March made a fine collection of neolithic flint implements from the district, which he presented to the town of Rochdale on his retirement from practice. A Fellow of the Society of Antiquaries, he was one of the founders of the Rochdale Literary and Scientific Society and president from 1891 to 1893. He was also a member of the Archaeological Institute of Great

Britain and Ireland, and after his retirement he joined the Dorset Natural History and Antiquarian Field Club. Dr. March was also a prolific writer on archaeology and philology, and discussed metaphysical questions, discoursing on "Life and Death" in South Place Chapel, Finsbury. Though very active in practice, Dr. March wrote but little on medical subjects, but at the Liverpool meeting of the Association, 1883, he read, in the Section of Surgery, a paper on "Resection of the ankle by an artificial Pott's fracture," based on a remarkable case under his care in the Rochdale Infirmary; it is to be found in the JOURNAL, 1883, vol. ii, p. 907.

He leaves a widow, who is also known in the literary world; a son, Dr. Geoffrey Colley March, in practice in Southampton; and a daughter.

THE LATE MR. ARTHUR E. BARKER.

SIR THOMAS BARLOW writes:

As Mr. Arthur Barker and I were colleagues for thirty years, I should like to be permitted to add a few words of personal reminiscence to your obituary notice. The remarkable developments of surgery during our generation in respect of abdominal disease as well as of lesions of the chest and of the nervous system have greatly increased the clinical and pathological interest of hospital consultations between physicians and surgeons. This was well illustrated in respect of Barker's early work on brain surgery in relation to ear disease and otherwise, and in his pioneer experiments on the surgery of the kidney and of the stomach, and, later still, in his study of spinal anaesthesia.

He was most painstaking in summarizing the results of the investigations of his predecessors, but he brought to his task a technique all his own and a critical judgement and infinite patience in attention to every practical detail which inspired his colleagues with great confidence.

He had a facile pencil, and was a clever carpenter, and was skilful in making his own models. He was an example to all of us in devotion to duty. With him the hospital always came first both night and day, and he was kindness itself to the patients, and secured the greatest efficiency from his residents, dressers and nurses.

As a clinical teacher he gave considerable—perhaps excessive—attention to the technique of surgery. But this was essentially his *métier*, and it eventuated in his circle of influence being especially that of senior and post-graduate students, who, long after they had left the hospital, referred to him for guidance and encouragement from all parts of the world. He was uniformly courteous to his fellow-workers, and singularly fair in his references to his contemporaries.

The general public has taken little account of the great sacrifices made by many medical men in the present war. Circumstances which I need not specify led to my becoming aware of Barker's absolute readiness to go anywhere and do whatever he was told without a moment's thought of his own comfort or advantage. He spoke of his experience at Netley in the simple, unquestioning discharge of duty as the time of his life, and whilst there he was in splendid physical condition.

When he was asked to go to Malta he did not hesitate, and a few days before he died he wrote to me from Salonica full of enthusiasm in his work, which was only clouded by his grave anxiety about the health of his soldier son.

In years to come I believe that his important contributions to surgical science will more and more secure their just recognition, and that his unfaltering devotion to duty and his loyalty to the highest ideals of conduct and life will remain an abiding memory to those who worked with him and knew him well.

A SURGICAL COLLEAGUE writes: The retirement of Arthur Barker from the active staff of University College Hospital last year, when he attained the age of 65, was naturally not felt as fully as would have been the case in normal times, as he had already been absent on active service for several months, but now the news of his untimely death at Salonica makes us realize that his activities in the hospital and medical school are really things of the past. Only those who were closely associated with him in the hospital know how entirely his whole heart

and soul were in his work, and there can be no doubt that in many directions British surgery owes more to Barker than is perhaps generally recognized. He possessed the faculty of quickly appreciating the value of any new discovery or development in surgery, and this, coupled with an unusual degree of manual dexterity and a striking aptitude in the elaboration of practical details, enabled him quickly to adopt such new developments and often to improve them in many important respects. Thus, while it cannot be claimed that Barker originated any important advance in surgical treatment, it may certainly be claimed that in several instances he brought new methods to the notice of British surgeons, and was largely responsible for elaborating the practical details upon which the success of the procedures depended. For instance, Barker's name would be deserving of memory, if for no other reason, on account of the prominent part which he took in introducing the use of spinal analgesia in this country. The papers which he published on this subject are a striking example of most painstaking clinical work. Every detail was so fully described that the majority of those who now employ the method will willingly own their indebtedness to Barker's work, and a few years ago surgeons and anaesthetists from all parts of the country came to obtain their first experience of spinal analgesia at his hands. Barker's final work in this direction followed on several years of the keenest interest in the whole subject of local and regional anaesthesia—a subject in which want of attention to a detail may so readily convert a success into a failure.

Throughout the whole of his hospital career Barker always had something new in hand; and, to mention only a few of his many activities, one remembers how at one time he was studying and elaborating the newer aseptic methods, at another keenly interested in the treatment of tuberculous joints and spinal abscesses, and at another taking a prominent part in promoting the surgery of the abdomen, especially in connexion with gastro-enterostomy and enterectomy. A reference to the surgical literature of the last thirty years will bring to light not a few proofs of Barker's share in the trend of surgical advance. The present position of abdominal surgery makes it difficult to remember that thirty years ago it was almost non-existent. It was at that time, in 1886, that Barker published what he believed to be the first successful case of gastro-enterostomy in this country, and it is interesting to note that in that year at University College Hospital the abdomen was only opened on seven occasions, exclusive of operations for hernia, and the ovariectomies performed in the gynaecological department. Not many men would show a better record of sustained activity for a period of nearly forty years.

As a teacher Barker was at his best when discussing and explaining some subject with which at the time he was particularly interested, and thus he was most attractive to really keen senior men. Such specialized and advanced teaching has its own value and takes its proper place side by side with that of a more general and ordinary kind. Those who now carry on the surgical work of the hospital unite in feeling that Barker's retirement, so soon to be followed by his death, leaves a gap which cannot easily be filled.

THE death occurred on April 13th of Dr. DAVID HADDEN, of Wexford. Dr. Hadden, who was 39 years of age, was the son of the late Dr. Hadden, infirmary surgeon, Wexford, and for the last fourteen years had had an extensive practice in Wexford, where he was held in high esteem by all creeds and classes.

Dr. HENRY MARTYN-CLARK, whose death occurred at his house in Comely Bank, Edinburgh, on April 10th, was the son and biographer of Robert Clark, the distinguished missionary of the Church Missionary Society, after whom Clarkabad in the Punjab was named. Henry Martyn-Clark was educated at George Watson's College and Edinburgh University, where he graduated M.B., C.M. in 1881, and M.D. in 1892. For twenty-five years he served as a medical missionary under the Church Missionary Society as head of the Amritsar Medical Mission in India. He then retired and returned to Edinburgh, where for several years he had held the post of lecturer on diseases of

tropical climates in Surgeons Hall School of Medicine, and had acted as university examiner in Oriental languages. He had a large private practice, and was much respected. He took a deep interest in the Edinburgh Jewish Medical Mission. In 1909 he was made an elder in St. George's United Free Church, and served also on the Foreign Missions Committee of the United Free Church of Scotland. He is survived by a widow and two sons, both medical men, one of whom is at the front, whilst the other is on his way home from the Cameroons. The funeral, to the Dean Cemetery, was on April 11th.

Dr. THOMAS PULLAR MONTEATH, B.A., R.U.I., died at Stocksbridge, near Sheffield, on March 8th, after a short illness, aged 56. He graduated M.B., C.M. at Edinburgh in 1893, and afterwards practised in Shaw (Lancs), Blackpool (Lancs), and Holme (Yorks). After leaving Holme, Dr. Monteath retired to Harrogate, but on the outbreak of the war acted for a time as house-surgeon to the York County Hospital, and also assisted several doctors with their extra work in Edinburgh, and latterly in Stocksbridge. He was a member of the British Medical Association, a good sportsman, and at one time a keen Rugby football player. He was of a kindly disposition, much liked by his patients and colleagues. Dr. Monteath, who leaves a widow and two children, was buried at Shaw.

COLONEL EDWARD ORD TANDY, Bengal Medical Service (retired), died at Mount Pleasant, Northam, North Devon, on April 10th. He was born on June 8th, 1835, educated at Trinity College, Dublin, and took the diploma of L.R.C.S.I. in 1857. He entered the I.M.S. as assistant surgeon on February 10th, 1859, became surgeon on February 10th, 1871, surgeon-major on July 1st, 1873, brigade surgeon on September 2nd, 1886, and deputy surgeon-general on April 2nd, 1889, retiring on April 2nd, 1894. He was given a good service pension on January 5th, 1894. He spent his whole service in military employ, and had seen a good deal of service on the frontiers of India. He was on the North-East Frontier in the Sikkim campaign of 1861; on the North-West Frontier in 1863, when he took part in the forcing of the Umbeyla Pass, receiving the medal and clasp, and in the Bezot expedition of 1868; also in the Afghan war of 1878-80, gaining the medal.

Dr. ISAAC OTT, a distinguished American physiologist, who died recently in his 69th year, took his doctor's degree at the University of Pennsylvania in 1869. In 1875 he was appointed demonstrator of physiology, and in 1877 lecturer on experimental physiology, in that university. In 1894 he became professor of physiology in the Medico-Chirurgical College of Philadelphia, a position which he occupied till 1914, when ill health compelled him to resign. He was a man of remarkable energy, for he combined research work and teaching with an exacting medical practice. Living at Easton, where he had his own laboratories, for more than twenty years he travelled three times a week to Philadelphia, where he lectured and demonstrated for five hours continuously. He was at one time president of the American Neurological Association. He was the author of a *Textbook of Physiology*, a fifth edition of which is now in the press, and of a large number of papers on physiological and pharmacological subjects.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. L. R. Lorentzen of Copenhagen, for a long period president of the Danish Medical Association, aged 63; Dr. A. Mendonça, head of the bacteriological institute of the medical school of San Paulo, Brazil, and founder of the *Revista Medica de San Paulo*; Dr. F. L. von Neugebauer, the well known gynaecologist of Warsaw, author of numerous writings on hermaphroditism and kindred subjects; Dr. Tiburcio Padilla, a leading member of the profession in the Argentine, sometime Governor of the Province of Tucuman, aged 80; Dr. F. Roques, physician to the Paris hospitals, aged 76; Dr. Henry Baird Favill, professor of clinical medicine in Rush Medical College, Chicago, and a very active social and political reformer, aged 55.

The Services.

INDIAN MEDICAL SERVICE.

PAYMENT OF SPECIALISTS.

A PRESS communiqué states that the Government of India has decided to modify for the period of the present war and to the extent noted below the rules for the grant of specialist pay laid down in Army Regulations, India, vol. i, par. 155 (D) (4):

(1) When an officer of junior rank is not available a lieutenant-colonel of the Royal Army Medical Corps or Indian Medical Service may, if considered qualified, be appointed to hold one of the sanctioned appointments of specialists, and he will be eligible for the extra pay authorized for such appointment.

(2) When two officers are not available to hold two special appointments an officer of either service may, if considered qualified, be appointed to hold both, and he will receive the pay authorized for them. The above decision has retrospective effect, to cover any cases in which lieutenant-colonels have held specialist appointments and where officers have held two specialist appointments.

EXCHANGES.

LIEUTENANT R.A.M.C., Regt. M.O., desires to change with officer holding a position in base hospital, casualty clearing station, or ambulance train, the latter preferred. Address, No. 1500, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

M.O. in Field Ambulance (T.F.), near London, gazetted Captain January, 1916, wishes exchange with medical officer on active service in any capacity. Address No. 1700, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Public Health

AND

POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL OFFICERS' ASSOCIATION.

A MEETING of the council of the Poor Law Medical Officers' Association of England and Wales was held on April 14th, when Dr. Gidley-Moore was in the chair. Correspondence was read from the Local Government Board, from which it appeared that boards of guardians would not be compelled to provide the cost of drugs that had become expensive owing to war conditions. The Board pointed out that the arrangements to be made in individual cases will depend on the terms of the agreement with the medical officer and the guardians, and expressed the hope that the guardians would be willing to take into account any case of an exceptional nature, if brought to their notice by the medical officer. The honorary secretary observed that guardians generally throughout the country had for many years agreed to pay the cost of certain drugs, and by raising the salaries of medical officers in not a few cases during the war had practically met in some cases the additional cost of drugs due to the war. The council thought that the Local Government Board ought to have made regulations, and that the obligation on the guardians should be made compulsory. The association's memorandum on the present Poor Law Orders advised that guardians should be required to find the drugs used in the treatment of their sick poor.

The council expressed general approval of the resolution of a conference of sectional Poor Law associations declaring that to create a new organization would be contrary to the interests of the service, but expressed the view that the rules of the National Poor Law Officers' Association should be altered so as to permit sectional associations to become branches.

A letter was read from the London and Counties Medical Protection Society, drawing attention to an instance in which a district medical officer who had accepted service in the R.A.M.C., and finding it impossible to get his practice carried on in his absence, had sold it, had been refused by the guardians repayment of deductions from his salary for superannuation. The honorary secretary considered that legally no return of such deductions could be claimed where the resignation of office was voluntary, but thought that a plea of legal compulsion might be urged if the medical officer was a Territorial before the war, or if he came under the Medical Service Act. The council registered its opinion that it was a great hardship that where a man resigned to serve his country and was practically compelled to sell his practice, he should be mulcted of contributions paid in the past for a superannuation he could never enjoy.

It was reported that the honorary secretary, Dr. Major Greenwood, and Dr. Withers Green had attended, as representatives of the association, a meeting of the Central Council for District Nursing in London, and together with all the other medical representatives had strongly opposed a suggestion that in connexion with the compulsory notification of measles, trained nurses should be permitted to attend mild cases, calling in a doctor only if urgent symptoms appeared.

The annual meeting of the association will be held during the first week of July at its office, 9, Copthall Avenue, and only formal business will be transacted.

Medical News.

DR. GEORGE OLIVER, formerly of Harrogate, left property of the value of £46,979.

PROFESSOR JOHNSON SYMINGTON has been appointed the representative of the Queen's University, Belfast, on the General Medical Council in succession to Sir William Whitla.

At a joint meeting of the Assurance Medical Society and the Medico-Legal Society to be held at 1, Wimpole Street, W., on Wednesday next at 5.30 p.m., Sir John Collie will read a paper on the effects of recent legislation upon sickness and accident claims.

A COURSE of eleven lectures on welfare work among women in factories will be given at the London School of Economics, Clare Market, Kingsway, London, beginning on Wednesday, May 3rd, at 5 p.m., when Mr. Seebohm Rowntree, director of Welfare Supervision for the Ministry of Munitions, will give an inaugural lecture.

MR. S. G. SHATTOCK, pathological curator of the Museum of the Royal College of Surgeons of England, will give demonstrations to medical students and practitioners on fractures, foreign bodies, and the results of inflammation, on Mondays, May 1st, 8th, and 15th, at 5 p.m. First-aid and ambulance students desirous of attending will also be admitted.

THE annual meeting of the Invalid Children's Aid Association will be held, by kind permission of the Speaker and Mrs. Lowther, at the Speaker's House, Westminster, on May 10th, at 3 p.m., when Cardinal Bourne will preside. Tickets of admission can be obtained from the Secretary, 69, Denison House, 296, Vauxhall Bridge Road, London, S.W.

A RECEPTION by the President and Council of the West London Medico-Chirurgical Society will be held at the West London Hospital, Hammersmith Road, W., on Wednesday, May 10th, at 8.30 p.m., when an address on the work of the British Red Cross Society will be given by Mr. James Cantlie, and methods and appliances will be demonstrated.

IN connexion with the annual oration of the Medical Society of London to be delivered on Monday next, at 8.30 p.m., by Sir StClair Thomson, M.D., F.R.C.P., on "Shakespeare and medicine," there will be an exhibition of portraits, books, drugs, and other objects of Shakespearean interest, which it is hoped will be kept open on the three following days from 10 a.m. to 5 p.m.

THE Wellcome Historical Museum, 54a, Wigmore Street, London, W., will be reopened on Wednesday next, when a special exhibition of Japanese charms and amulets, collected by Mr. W. L. Hildburgh, M.A., will be on view. The collection is concerned especially with medical folklore. Visitors will be admitted on presentation of a visiting card on any week-day. The museum opens at 10 a.m. and closes at 6 p.m., except on Saturday, when it closes at 1 p.m.

THE *Journal of Immunology* is a new bi-monthly periodical, the first number of which appeared in February of the present year. It is the official organ of the Society for Serology and Hematology, and of the American Association of Immunologists. The editor is Dr. Arthur F. Coca, with an international advisory board of nine members, among whom are Drs. Simon Flexner, Robert Muir of Glasgow, F. Nuttall of Cambridge, W. H. Welch of Baltimore, and Sir Almroth Wright. The new journal is published at Baltimore, and has an English office at the Cambridge University Press.

THE work which the brothers Neve are doing and have been doing in connexion with the Church Missionary Society Medical Mission at Kashmir is admirable. The report for 1915 shows that the war has not injuriously affected subscriptions, donations, and offertories, which are indeed more than in the preceding year. Dr. Arthur Neve was at home on war service ("Kitchener" Hospital at Brighton). The work in Kashmir was carried on by Dr. Ernest Neve and Dr. Somerton Clark. As usual, surgical cases were very numerous; chloroform was administered in 1,309 cases with no fatality. There were 4,287 operations in all, with 18 surgical deaths; over 16,500 out-patients were seen. A sinister feature in the returns is the increasing frequency of tuberculosis; "deaths in childbirth and deaths from tuberculosis head the list of fatalities in the city" of Kashmir.

B. M. IWANOW has performed (*Medizinsk. Obosreniye*, 1916, N13-17) sixty-three operations under local anaesthesia by the quinine and urea hydrochloride solution prepared by Parke, Davis, and Co. They included operations on fibromata, cysts, tuberculous glands in the neck,

varicose veins, on bones, for removal of shrapnel particles, and for hernia. The effect of the anaesthetic lasted sometimes several days. The fact that the fluid was issued in ampoules was accepted as guaranteeing its sterility. Besides the subcutaneous injection, Iwanow sometimes dropped some of the liquid over the cut tissue; in this way the anaesthesia was deepened and prolonged. The anaesthesia developed about ten to fifteen minutes after the injection; the longer the interval the more complete was the anaesthesia; Iwanow, therefore, recommended that the injection should be used half an hour before the operation. His conclusions are: (1) Quinine and urea hydrochloride caused in most of the cases full anaesthesia of the tissue; (2) the preparation acts as a vaso-constrictor and diminishes haemorrhage; (3) it is not injurious; (4) the liquid should be injected half an hour before the operation; (5) the anaesthesia, as a rule, lasted two to three days.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

PRURITUS OF FACE.

COUNTRY DOCTOR asks for suggestions on the treatment of a girl, aged 22, healthy except that she has been subject from childhood to attacks of intolerable itching over the cheeks and jaws at irregular intervals. The attacks, preceded by subcuticular roughness, last for an hour or two but recur daily for about a week. The application of x rays brought on an exceptionally severe paroxysm of pruritus.

ANSWERS.

ENLARGED TONSILS IN A SINGER.

F. F. T. H. will find much information in our review of Dr. Harry Barnes's work, *The Tonsils: Faucial, Lingual, and Pharyngeal*, in the JOURNAL, 1915, vol. ii, p. 569, in Dr. Mechan's letter, *ibid.*, p. 948, and in further correspondence in the JOURNAL of January 1st, 1916, p. 33; January 8th, p. 71; and especially January 15th, pp. 111, 112, where Dr. J. B. Horgan and Dr. Syme dwell on the enucleation of the tonsils in professional voice producers. Dr. William Hill published a review of tonsil operations from Celsus to the present day in the *Journal of Laryngology*, December, 1914.

LETTERS, NOTES, ETC.

INHERITED ABNORMALITY OF THE FINGERS.

DR. H. DRINKWATER (Wrexham) has been asked by an American surgeon to find the whereabouts in Great Britain, probably Scotland, of a family having inherited abnormality of the fingers consisting of ankylosis of the proximal and middle phalanx in each finger.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

Notes on Military Orthopaedics.

II. ON SUTURE OF NERVES, AND ALTERNATIVE METHODS OF TREATMENT BY TRANSPLANTATION OF TENDON.

BY

LIEUTENANT-COLONEL ROBERT JONES, CH.M.,
F.R.C.S.I. (HON.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

THERE are few problems more urgently needing solution at the present moment than those involved in the treatment of limbs disabled by injuries involving nerves. The conditions vary and are often very complex. The nerve may be irretrievably injured beyond all hope of suture; it may be entangled in cicatricial tissue; one or more of the muscles it supplies may have suffered grave lesions, varying from partial to complete destruction; the tendons or muscles themselves may be bound down by adhesions, or the joint or joints the muscles govern may be stiff or ankylosed, or held in a deformed position by a skin cicatrix, or more than one of these hampering conditions may be present. The simple condition, where the nerve or some of its fibres receive a clean severance, is exceptional.

If once these facts are realized it will require no argument to establish the proposition that certain orthopaedic problems must be mastered in connexion with the suture of nerves if proper restoration of motor function and of the normal efferent and afferent connexion between muscle and the central nervous system are to be secured. In certain fortunate cases the conductivity of the nerve is restored and good muscular function may result. In other instances, although the conductivity is restored, the function of the muscles and joint may not be regained because certain fundamental principles have been neglected. There are other cases in which the conducting power of the nerve is not properly restored, and yet others in which, owing to extensive destruction of the nerve, any attempt at suture would be futile. We must therefore be prepared with alternative methods in order to secure for the patient a satisfactory limb.

LATE SUTURE OF NERVE.

With regard, however, in the first place, to late suture of the nerve, certain general principles must be borne in mind. These are:

1. The correction of contractures of skin or muscle and all the anatomical constituents, from skin to bone, on the concave aspect—that is to say, on the side of the abnormal direction the contracture takes.
2. When possible, the freeing of joints from all adhesions and the restoration of the mobility of the joint in all cases where ankylosis is threatened.
3. The maintenance of the paralysed muscles in a position of relaxation throughout the period of recovery.
4. The practice of massage during the recovery, but without once allowing the relaxed muscles to be stretched.

In short, the principles and their application coincide with those I have so often emphasized in the treatment of poliomyelitis.¹

1. Freeing the Muscles.

In the first place, it is necessary to free the muscles from all mechanical obstructions to their action. If this be not done they cannot respond to stimuli sent to them through the nerve, and therefore cannot in their turn send the answering afferent impulse which is necessary to bring the apparatus into proper working order. It is essential to dwell on this point, inasmuch as many operations are being performed while the muscles and joints are stiff. This stiffness is not due to the nerve injury, but to the consequences of trauma and sepsis affecting the muscles, tendons, blood vessels, nerves and ligaments about the joint. When we realize how anaemic an unused muscle becomes, we shall not delay in giving help to prepare it for the reception of nerve impulses.

2. Mobility of Joint.

In the second place, where the joint is threatened with ankylosis, every effort should be made to restore its function.

Operation on the nerves is doomed to failure if these fundamental principles be disregarded.

3. Relaxation of Muscles.

Thirdly, the importance of keeping the partially paralysed and overstretched muscles in relaxation during treatment has been so forcibly brought home in ordinary civil practice in the treatment of residual paralyses after poliomyelitis, lead palsy, injuries of the brachial plexus and of isolated nerves, that it should be scarcely necessary for me again to call attention to it. Nevertheless, visits to wards prove that this elementary orthopaedic measure is too frequently entirely omitted by surgeons who have performed suture of injured nerves. Thus we find men who have had the musculo-spiral sutured allowed to walk about with the hand dangling in palmar flexion instead of its being kept continuously in dorsiflexion! By letting the hand hang in palmar flexion the muscles supplied by the sutured musculo-spiral, which can only recover if kept relaxed, are allowed to become stretched. The result is that the fingers and hand do not regain, can hardly be expected to regain, full normal function. A similar grave error is perpetrated often in the case of the external popliteal nerve also, with the same disappointing result in the foot. Frequently I have noticed that the foot of a patient whose popliteal nerve has been sutured is allowed to remain in an equinus position! Sometimes, indeed, the operation is even performed while the tendo Achillis is contracted. Were it not so frequently happening I should feel ashamed to refer to this matter, but as it is happening I again urge surgeons who suture nerves to insist that the affected muscles be kept in complete relaxation until power returns. The most skilful operation performed on the most suitable case will prove a fiasco unless the affected muscles are continuously kept relaxed until recovery takes place.

In some cases it will be found not only that no provision is made for the muscle to be in the most favourable condition to respond to the earliest motor impulses which come through the block in the nerve, but, further, the mechanical condition of the muscle as to function seems to be entirely neglected, and suture of the nerve is performed when the paralysed muscle or the joint on which it acts is immobilized by cicatricial adhesions. If restoration of function is to follow nerve suture, the new axis cylinders growing through a cicatrix must of course be enabled to establish some sort of normal relation as to function with the end organs in muscle. If the muscle is mechanically disabled from making any response, it is absurd to hope for good functional result, even though the physiological processes of repair of the nerve be perfect. I desire to emphasize again the fundamental principle of procedure—namely, that the restoration of the mobility of joint and muscle must precede the operation of nerve suture. It is useless to attempt it otherwise.

4. Voluntary Use and Massage.

Fourthly, for precisely similar reasons, it is important that the patient should as soon as possible exercise the limb in normal movements. In the case of the lower limb this usually means the application of some apparatus designed to prevent strain on the recovering muscles while the patient is permitted a moderately free physiological use of his limb. In order to make the foregoing observations more lucid to those who have not followed my writings, which are based on the late Mr. H. O. Thomas's theory of "muscle lengthening," I will briefly indicate their tenor.

It is well, in view of the enormous number of injuries to nerves occurring in this war, to emphasize the fact that principles applicable in poliomyelitis are applicable here. When speaking, some years ago, of the results of acute poliomyelitis, I pointed out² that, though the disease might permanently destroy motor cells in the anterior horns of the grey matter, so rendering the muscles dependent upon them for ever useless, unless nerve transplantation might at some later date come to their rescue, yet complete destruction was fortunately the rarer condition. The clinical evidence afforded by rapid and

complete recoveries from complete paralysis and the very many partial recoveries proved that the motor cells concerned had suffered from temporary injury and had not been destroyed. Something had happened to make the muscle incapable of responding to motor stimulus. Whether this was to be attributed to the absence of afferent muscle-sense stimulus, as seemed probable, or whether it was due to some other cause, it was clinically certain that the nerve cells became partially inactive, not extinct, and that with appropriate treatment of the muscle or group of muscles functional activity could be reinstated. When a muscle governed by a live cell, or rather a group of live cells, fails to act, the disability may be spoken of as functional. Of this disability the great outstanding cause is overstretching of muscle fibres. A surgeon must recognize the difference between a truly paralysed muscle and a muscle which is over-stretched, and must know how to distinguish the one condition from the other.

The first essential of treatment is that the muscle or muscular groups must be prevented from being over-stretched. If the wrist is, for instance, allowed to remain flexed the flexor muscles undergo adaptive shortening, and the extensors become over-stretched and consequently placed at a mechanical disadvantage. This point is well illustrated by dropped wrist from lead poisoning. The lesion here may be either in the cord or in the nerve trunks; in either case the muscles cease to be controlled by their nerve centres, and the patient goes about with his wrist flexed by gravity, and the extensor muscles become disabled by continuous overstretching. As the condition is usually bilateral, an interesting experiment to test my contention may be made, if the case be of some weeks' standing, by placing one of the paralysed arms on a splint to keep the hand dorsiflexed. It will be found that recovery will be much more rapid on the side on which the extensors are relieved from overstretching than on the other neglected side. When a muscle is deprived of the natural motor stimuli, its condition from the point of view of function and nutrition is the same, whether the absence of stimuli be due to inactivity of the central nerve cells or to interruption of the conducting paths along the peripheral nerves. Its motor function is suspended, its nutrition suffers, it becomes anaemic, and it may easily be over-stretched by gravity, by the unrestrained action of the opposing muscle, or by these two forces acting in combination. If the wrist and fingers are kept in extreme dorsiflexion, the extensor muscles, thus relieved of strain, undergo adaptive shortening, and soon begin to respond to the constant stream of tonic stimuli sent to them by efferent impulses; later they come under the higher control of the voluntary centres.

Another cause of persistence of functional disability is an unequal degree of recovery in opposing muscular groups.

Deflection of Body Weight.

A most potent factor for evil is what I have called the erroneous deflection of body weight, which, for physical reasons, operates chiefly in the lower limbs. If, for example, there be weakness in the tibial group and the patient be allowed to walk, the valgoid deformity will

constantly increase, the tibial muscles will be more and more stretched, adaptive contraction will affect the peronei, and structural alteration will ensue in the tarsal bone, terminating in a troublesome flat-foot. All these untoward results may be avoided by simple treatment on sound scientific principles; a little alteration of the boot which, by raising the inside of the heel of the boot, will deviate pressure from the inner to the outer side of the foot, may suffice. When we have to deal with a group of muscles in which the power is only slightly impaired, the muscular

balance may be restored by over-developing the weaker group. If, for instance, the peronei are weak, but the foot can quite easily be placed in the everted position, then massage and exercises may reasonably be expected to succeed. But if the foot cannot be everted because of adaptive shortening of the tibial tendons, then massage and exercise of the peronei will be perfectly useless until such time as the deformity has been corrected and the over-stretched muscles kept relaxed for a sufficient period to permit them to recover by interstitial shortening.

LATE RECOVERY OF MUSCLE POWER.

But before any operations are performed affecting the mobility of a joint, every use should be made of available muscle power. No surgeon should operate on these cases until he has fully satisfied himself whether or no it be possible to restore the apparently paralysed muscle. Neglect of this precaution produces such a distressing occurrence

as the unexpected recovery of muscles which were ignored because assumed to be paralysed. For example, a patient was brought to me once with a partially ankylosed knee. The operation of arthrodesis had been performed with a view of bringing about bony ankylosis. As an arthrodesis the operation had failed, for the knee had a short range of movement. As an experiment, illustrating the principle we are discussing, it was very successful, because the quadriceps was acting with considerable strength. Prolonged fixation had relieved the quadriceps from all strain, and restoration of function resulted. This case exemplifies the mistake of taking for granted that a muscle is paralysed without first making quite certain that it is *really* paralysed. It is only possible to make quite certain by relaxing the muscle and thus putting it into the position most favourable to recovery for a sufficient length of time. Electrical tests cannot be relied upon to give this information.

Treatment to Promote This.

The first stage of treatment is the correction of existing deformity. When deformity has been corrected the limb should be kept immovable until the ligaments, muscles, and even bone have become of normal length and shape. The continuity of treatment must be maintained or a relapse will result. This point is fundamental, and neglect to observe it spells failure, as the slightest stretching of a muscle on the point of recovery disables it again. All the good work may be thwarted by a single indiscretion. I cannot emphasize this point too strongly. For instance, let us take the case of a drop-wrist which has been placed in a splint designed to dorsiflex the hand and wrist. The position must be constantly maintained. The hand must

DIAGRAMS ILLUSTRATING TRANSPLANTATION OF TENDON INTO TENDON UNDER VARIOUS ANATOMICAL CONDITIONS.

FIG. 3 A.—Showing the tendon which is to be transplanted about to be passed through a tunnel in the other tendon. The tunnel is being dilated to receive the transplanted tendon.

FIG. 3 B.—Transplant in position. The angulation is dealt with as shown in Fig. 3 C.

FIG. 3 C.—In order to overcome angulation a slit is made in the upper part of the receiving tendon, which is then wrapped round the transplanted tendon.

FIG. 4 A.—Tendons about to be pulled through another before suturing.

FIG. 4 B.—The divided ends of three tendons passed through another tendon in its course.

FIG. 5 A.—Showing transplanted tendon about to be passed along a tunnel in the receiving (active) tendon.

FIG. 5 B.—Tendon passed along course of active tendon.

FIG. 7.—Tendons inserted into either side of active tendon.

not be allowed to flex for a single moment until recovery has occurred. Even while the patient washes, the hand must be held dorsiflexed.

The clinical test of the recoverability of a muscle, therefore, depends on an experiment. Let it be kept for a prolonged period—for at least six months—in a position of relaxation. This test should always be made before condemning any muscle, no matter how long the period for which it may apparently have been paralysed. When, therefore, one reads in textbooks statements to the effect that we are to despair of the return of power after a certain length of time, we can quite well afford to ignore the advice unless in addition to this time test there has been an uninterrupted muscular relaxation during that time.

These are views which I have without ceasing urged upon my professional brethren as applicable to infantile paralysis. They are equally applicable, with certain modifications, in the case of gunshot injuries. It is obvious that in infantile paralysis long mechanical treatment can do no harm. This is not so in the case of a soldier in whom a nerve has been injured. If suture is to give any promise of success there must be a limit to conservative methods. In any case, an exploration of the nerve is a harmless procedure.

TENDON TRANSPLANTATION IN GUNSHOT INJURIES OF NERVES.

In recommending tendon transplantation in gunshot injuries I have profited by the experience gained in anterior poliomyelitis. I have frequently performed tendon transplantation with success in the adult in cases in which isolated nerves have been destroyed. Similarly unrecorded cases have been operated upon by my friends Mr. Thelwall Thomas and Mr. Bickersteth. At the Military Orthopaedic Hospital, Liverpool, my colleague, Captain McMurray, has at this moment three successful cases in which transplantation has been done for musculo-spiral paralysis. As

I have previously indicated, the object of a transplantation is to improve or restore muscular balance. It is not justified unless it improves function. There is little satisfaction to a patient if the transplanted muscle merely responds to faradism, or even makes a feeble movement by the effort of the will. It must be, or give the promise of becoming, a substitute for the muscle it supplants. It can only be judged by its ultimate usefulness.

A tendon may be transplanted in order to restore the balance between opposing groups of muscles by helping a redistribution of power, or its attachment may be slightly altered to prevent deformity.

Recognizing that the principles involved in tendon transplantation are the same in both conditions, I will briefly describe in the second part of this communication certain transplantation operations I recommend for various injuries.

As a preliminary I give here a series of diagrams Figs. 3, 4, 5, 6, and 7, illustrating methods of transplantation of tendon into tendon applicable under various anatomical conditions.

(To be continued.)

LIEUTENANT-COLONEL C. C. MCCULLOCH, Medical Corps, U.S.A., Librarian of the Surgeon-General's Office, Washington, D.C., informs us that the Army Medical Museum there possesses a valuable collection of medals relating to medicine, started and fostered by the late Dr. John S. Billings. It is desired to add to this collection and complete it as far as possible. Colonel McCulloch invites the assistance and advice of physicians who are collectors of medical medals. Gifts of medals are asked for, and also copies of catalogues for sale, as the museum is in command of money for the purchase of individual medals or private collections.

A CASE OF CONGENITAL ATRESIA OF THE DUODENUM TREATED SUCCESSFULLY BY OPERATION.

By N. P. ERNST,

CHIEF SURGEON AT ST. ELIZABETH'S HOSPITAL, COPENHAGEN,
DENMARK.

THE following report may prove to be of some interest, because there is only one instance known to me in surgical literature of a case of congenital atresia of the small intestine in which a surgical operation was successful. In that case, however, recorded by P. Fockens, of Rotterdam, the atresia lay a little above the ileo-caecal valve, so that the following will be the first instance ever reported of congenital atresia of the duodenum successfully treated by an operation.

Congenital Atresia of the Duodenum below Vater's Papilla: Duodeno-enterostomy: Recovery.

The patient was a boy, born on November 19th, 1914; labour was spontaneous. I was present at the birth, and for some time saw the infant almost daily. The parents were healthy, but although they had been married for three years this was their first child. The child was robust at birth, and there was no history of deformity in its family. It weighed 4,300 grams, and showed no external sign of any malformation. From the first the child always vomited after suckling. On the third day it took the breast more actively than at first, but two or three hours later it began to vomit, with almost explosive violence. Very little urine was passed, and the motions were limited to a small amount of typical meconium, without a particle of digested milk. The child was treated both with castor oil and enemata, and the oil, at all events at first, caused a larger quantity of meconium to come away. Rectal examination revealed no abnormal condition of the bowels. The child lost weight rapidly, to the amount of about 700 grams during the first week.

I diagnosed the case as high-seated intestinal stenosis or atresia and suggested to the parents that it would be best to operate on the infant; but they wished first to consult a children's specialist, Professor Monrad. In all essentials he shared my view about the condition of the child; but its general health being otherwise so remarkably good, he considered that we could not exclude the possibility that the stenosis might perhaps be remedied by suitable medical treatment, such as that which he successfully used for congenital pyloric stenosis. He thought it therefore advisable to change the infant's diet, and wash out the stomach daily; but the vomiting continued, and during each of the following three days the infant lost 30 grams, so that its weight on November 29th was 3,490 grams. We both saw that an operation was imperative, and on the morning of November 30th the child was removed to St. Elizabeth's Hospital. Its general condition was still fairly good. The temperature, taken daily during the last days at home, was normal. Stethoscopic examination showed no thoracic disease. The abdomen was soft to the touch, without distension or swelling; now and then faint peristaltic movements were noticeable on the left side. The umbilical wound was well healed; it had been dressed since the shrivelling of the cord with cotton-wool moistened with 1 per cent. silver nitrate solution.

Operation.

Directly after admission the stomach was washed out, and the skin having been disinfected with soap, water, and spirit, abdominal section was undertaken under ether. The incision was made a little to the left of the middle line, and was between 7 and 8 cm. long. After the anterior sheath of the rectus had been laid bare, Mosetig batiste was sewn to the edges of the skin with continuous silk

suture so that the integuments were completely covered. On opening the peritoneum the dilated stomach protruded into the wound, and was traced along the dilated pylorus into the duodenum, which was uniformly of about two fingerbreadths in width, as far as it could be traced to the upper side of the transverse mesocolon. But below the colon, where the intestine reappeared, at the flexura duodeno-jejunalis, it was seen to have collapsed to the calibre of an ordinary pencil, about 8 millimetres in diameter. The remaining part of the small intestine was examined quickly, especially its lower portion, but no stenosis was discovered.

On that account I made a duodeno-entero-anterior anastomosis—that is to say, a coil of small intestine about four inches below the flexura duodeno-jejunalis was drawn up in front of the transverse colon, and united to the duodenum about the junction of the pars superior and pars descendens. Anastomosis to the lower part of the pars descendens was impracticable.

The intestines were held during the operation by Doyen's straight soft intestinal forceps; first, continuous sero-serous suture was applied, then a continuous suture through all the layers the whole way round; and, finally, a continuous sero-serous suture on the front (all sutures of Turner's silk No. 1). When a stomach tube was passed through it a good deal of air and greenish fluid was discharged. The intestinal forceps was removed, and immediately afterwards the jejunum began to fill. The walls of the abdominal incision were united with deep catgut sutures, and interrupted silk sutures were applied to the sheath of the rectus and skin. The dressing was fixed with mastisol. The child was little affected either by the anaesthetic or by the operation, which lasted about 1½ hours. It took 35 c.cm. of ether.

A few hours after the operation I began to give the infant a weak mixture of milk and water, about 30 c.cm. every two hours; it vomited a little several times in the course of the day, and at 8 p.m. more violently, so that the stomach tube was used, and a little greenish fluid evacuated. At 7 p.m. an enema was given, but without any result.

On December 1st the rectal temperature was 37.7° and 37.4° C. There was again much vomiting. On December 2nd the temperature was 37.4° and 37.1° C. Since the previous day the infant had had eleven meals of 30 c.cm. each. He had vomited three times during the day, and on December 1st was given one teaspoonful of castor oil twice and three enemata, and had altogether four alvine discharges, which without any doubt contained digested milk. The child's appearance was good. No more violent vomiting occurred, but there was slight sickness for some days; the bowels acted daily, and the stools soon appeared quite normal. The temperature also fell to normal. Five days after the operation the child was sent home to be suckled by his mother, who could not be admitted to the hospital. The dressings remained untouched till the fourteenth day, when all sutures were removed; the wound had healed by first intention.

The infant's weight decreased during the first five days 90 grams more, and was now 3,400 grams, or 900 grams less than at its birth; but afterwards it increased continuously, and considerably more than 250 grams a week for several months. We soon allowed meals every third hour, and when a few weeks had passed the child could sleep the whole night without food. He is now remarkably quiet for his age and is vigorous and well developed; his weight in the middle of October, 1915, was 11,200 grams.

COMMENTARY.

As I mentioned in the first part of this report, medical literature relates but one instance of the recovery of an infant operated on for congenital atresia of the small intestines.¹ The child was a boy, born at term November 6th, 1910; he was taken to a free consultation; it was stated that he had never had any movement of the bowels and that he had vomited constantly ever since his birth

Duodeno-enterostomy performed on an infant. A, Stomach and dilated pylorus. B, B, Duodenum above transverse mesocolon. C, C, Transverse mesocolon. D, D, Atresic portion of duodenum behind and below transverse mesocolon. E, Flexura duodeno-jejunalis. F---G indicates the anastomosis between the duodenum at F, about the junction of the pars superior and pars descendens, and the jejunum at G, four inches below the flexura E, the jejunum being drawn up in front of the mesocolon.

The abdomen was rather swollen and flatulent. On November 14th laparotomy was performed, and complete atresia of the small intestine detected. At a point normally between the middle and lower third of the small intestine the bowel was completely missing, being represented by a cord along the edge of the mesentery connecting the blind ends. After applying Doyen's intestinal forceps, entero-entero-anastomosis was performed with two rows of silk suture. After the operation the temperature rose to 105.8° F., but soon fell and became normal, and five months later the child had quite recovered.

Congenital atresia of the small intestines is, on the whole, very uncommon. In the foundling hospital at Petrograd Theremin reported nine cases among 150,000 children, and I myself have come across only two cases among 41,000 children in the Royal Lying-in Hospital at Copenhagen.

Different hypotheses have been advanced to explain the pathogeny of atresia of the small intestine, but the most probable is that advanced by Tandler,² the Viennese anatomist. On examining eleven human fetuses aged from 30 to 60 days he found that on the thirtieth day an epithelial proliferation begins in the duodenum, and results in a more or less complete obstruction of its lumen. This obstruction is greatest on about the forty-fifth day, and seems to have ceased on about the sixtieth day. According to Tandler's theory, congenital atresia of the small intestine is due to persistent physiological epithelial obstruction.³ This theory was afterwards confirmed by E. Kreuter, and especially by H. Forsner⁴ of Stockholm; the latter writer maintains that a narrow epithelial stenosis may become a complete atresia later on in fetal life, and in this way he explains the presence of meconium below the atresia, as noted above in the report of my own case.

I think all will agree that the treatment of atresia of the small intestine must be surgical, but as to the kind of operation opinion still differs greatly. From the perusal of cases recorded (even during the later decennia), it will be noticed that in an astonishing majority only enterostomy has been performed, and it has always resulted in sudden death, associated with an enormous rise of temperature; yet even in 1902 H. Braun⁵ recommended this procedure as the normal method for deep-seated atresia of the small intestine. Naturally, I cannot share Braun's view; on the contrary, I maintain that if we are dealing with a fairly strong infant, without any other signs of bad deformity, we ought to perform a laparotomy, making the abdominal incision large enough to enable us to see where the obstruction is seated, and also to make sure that no second stenosis be present. Then the operator should make the anastomosis which the particular case demands. It will very seldom be possible to postpone the operation as long as in my case. As yet I have not been able to discover any account of anastomosis being performed for atresia of the duodenum. It will be noticed in the history of the recorded cases that while almost all the infants that have undergone this operation developed an exceedingly high temperature, although only enterostomy was undertaken, the infant operated on more radically by Fockens also got very high fever, yet completely recovered.

As we cannot suppose that failure is due in every case to defective personal asepsis on the part of the surgeon, we must direct our attention to the special source of the infection in the child itself. There is a risk on two sides—namely, from the skin and from the contents of the intestines. As is well known, the integuments of an infant during the first weeks of its life are always infected from the umbilical wound, and the delicate skin cannot stand any strong disinfectants. In order to eliminate this danger, I in the first place dressed the umbilical wound with cotton-wool moistened in a 1 per cent. solution of silver nitrate, before the putrefaction of the cord; and what was of still more importance, I sewed Moseig batiste to the margins of the wound before laying open the sheath of the rectus, so that the intestines and compresses could not touch the skin. It cannot be doubted that the stagnant and decomposed contents of the stomach involve a great danger of peritonitis; it is necessary, therefore, if there be any suspicion of atresia, that the greatest care and cleanliness be taken in the feeding of the infant, hence only an experienced nurse should be entrusted with a case of this kind. The strictest care

should be taken to prevent any of the contents of the intestines getting into the peritoneum during the operation. I chose the antecolic type of anastomosis as being the easiest to perform. The fact was that I was not able to apply it to the lower part of the duodenum on account of the adhesion of that part of the bowel to the posterior abdominal wall. A retrocolic anastomosis might for purely theoretical reasons have seemed to allow of almost normal anatomical conditions, but I consider that the drawing of the gut through the mesocolon and the more difficult application of anastomosis would have increased the risk of the operation considerably. Later, on reading Fockens's report, I was greatly interested in the fact that he had argued in a similar way.

SOME HINTS ON TIME SAVING IN OPERATIONS.

By EDWARD HARRISON, M.A., M.D., F.R.C.S.,
HONORARY SURGEON, HULL ROYAL INFIRMARY.

THAT an operation performed rapidly, without, of course, in any way impairing its efficient performance, is desirable in the interest of the patient, is, I think, admitted by all. Indeed, in many cases—for instance, a case of ruptured ectopic pregnancy—rapidity in operating may easily make the difference of life or death to the patient; and as necessarily the surgeon has frequently to undertake such cases, it is imperative that he should be able to act promptly, quickly, and safely. This is, however, not the point I am about to discuss; I am taking it for granted that it is better for the patient that any operation should be expeditiously performed. The gain, too, is not confined to the patient, but is time saved to the busy surgeon, and in hospital work, where operation succeeds operation, a saving of time is a great gain to all concerned.

How is time to be saved? First and foremost, I most emphatically state that it lies in efficient co-operation between the surgeon, house-surgeon, and theatre sister. I am, of course, now speaking of hospital work; any work in private must necessarily fall short of this. By constantly working together the surgeon, house-surgeon, and sister play into each other's hands and assist one another as do partners in any game—bridge or football, for instance.

Of the trio, perhaps the sister plays the most important rôle; a sister, such as we have at present at the Hull Royal Infirmary, must save hours in the course of a month's operating. A good sister knows the peculiarities of each surgeon she has to work with, and is ever ready to hand him the instrument he needs, never keeps him waiting a moment while she threads a needle but is ever alert, so that I often wonder that after five or six hours' work it is possible to remain good tempered and willing for anything further.

Then, too, much time is saved in a hospital between operations by efficient drilling of the nurses. I often sit and admire the way in which preparations are made for the next operation. After the dressings are applied the porters are summoned, the house-surgeon wheels the table out of the theatre, and then changes his gloves. The sister changes hers, and prepares the instruments for the coming case; one nurse swabs down the floor with a squeegee, another takes the bowls away, and replaces them with freshly sterilized ones; no one is in a hurry, all works as smoothly as a silent running motor car, and the theatre is ready before the anaesthetist has the next patient under.

After this, then, given a capable house-surgeon and a reliable theatre sister, what can the surgeon himself do in the saving of time? This, of course, varies with the individual; a man who in his youth has been accustomed to use his fingers as individual digits, who has practised such arts as carpentry, mechanical drawing, or piano-playing, has all his fingers under control, and can use each one as required without any effort. The boy who is fond of using his fingers in any deft way, such as familiarity with the different knots in use among sailors, one who delights

in conjuring tricks with string, wire, etc., has developed his fingers to an invaluable extent if he is to become a surgeon.

Before the days of anaesthetics the surgeons felt the need for rapidity in operating, and when we read of the deeds of the great surgeons of those days one can only marvel at their dexterity, but to amputate at the hip-joint in half a minute demanded a very different dexterity from what is required to-day. Then the sutures were introduced with what would be regarded as a packing needle, and no effort was made for an artistic result; the main thing was to accomplish the operation as rapidly as possible.

In what ways, then, can the modern surgeon improve on his predecessor in time-saving devices?

Let us consider what is required in almost every modern operation, as if in manipulations that have constantly to be carried out a second can be saved in each motion a considerable amount of time is saved in the course of a year.

A very large amount of time is occupied in every operation in suturing; take gastro-enterostomy or intestinal anastomosis as examples; here really accurate and artistic work is demanded. When one observes the way that ladies work with the needle assisted by a thimble one is constrained to ask why surgeons do not adopt a similar device? Watch the accuracy and speed with which they do their work. Why are we so slow to adopt their ways? The fact is that we are hidebound by tradition, and to meet modern requirements have had to devise variously curved needles which can be pushed through with one hand, a hand composed of a bunch of fingers with an opposing thumb, and pulled out by another similar clumsy organ.

Some six or seven years ago I set myself the task of learning to sew with a thimble, and I am sure that it will well repay any surgeon to spend a quarter of an hour each day under the direction of his wife in learning to sew. I began by sewing odd pieces of rag together, and was soon promoted to hemming such coarse articles as dusters, but after a few weeks' practice I was able to hem a fine cambric handkerchief quite accurately and with some approach to speed. I found it best to have the thimble on the third finger, using the thumb and two first fingers to hold it, and I still use that method. To any beginner, however, I should advise the usual method adopted by the sempstress, and become accustomed to having the thimble on the second finger, as, although you will not have at first the security of grasp which is given by using the two first fingers and thumb, this will be compensated by the greater directive control of the thimble. Still, by using the two fingers with the thimble on the third, the point can readily be made to pursue a semicircular course. When some proficiency is obtained, the first feeling that something has been gained is that the needle is so easily directed that its pointed portion is at once taken hold of by the thumb and forefinger of the same hand and pulled through, leaving the left hand entirely free for other work, such as steadying the part to be sutured. For example, when a piece of omentum is tied and cut off, it is desirable to bury the cut surface in order to prevent it forming adhesions; the stump can readily be invaginated and the mass held in the left hand while the right hand does the suturing; no assistance is needed, and while this is being done the house-surgeon can be replacing bowel or otherwise advancing the operation.

It may be urged that there are many positions in which it would be impossible to use a straight needle in preference to a curved one; this is so, but to a less extent than would at first be expected. It might be thought that for suturing the vagina or cervix after hysterectomy, where the surgeon has to work deeply in the pelvis, that a curved needle would be essential, but it is not so. In such circumstances a short needle must be used, the parts can be steadied by forceps, and only one hand has to be introduced into the pelvis. It is not in such cases as this that the straight needle is contraindicated, but rather in those in which there is no space available for the depression of the eye of the needle, as in sewing up the abdominal wound after an operation on the stomach or gall bladder in a *fat* muscular man; here, with rigid structures, I have often to use a curved needle, but this hardly ever happens in wounds below the umbilicus.

Second to acquiring the facility with the thimble I would place the ability to tie a surgeon's knot with one hand. The method of doing this was described by Borchgrevink.¹ After reading this article I was convinced of the importance of being able to tie the knot with one hand, and for some months carried a piece of string in my pocket and practised at the knot in any spare interval, passing the string through a buttonhole of my coat. It is a difficult knot to learn from a written description, but the time given to acquiring facility in its use will be very well spent by anyone. The first part of the knot is quite easy, but the second is at first distinctly difficult, and to learners I would give the hint that success in rapidly tying the second part lies in having plenty of laxity in the hand holding the distal end of the thread. Facility once gained the pleasure in knot-tying is greatly enhanced, and one uses, in preference, the single-handed method in cases where the double handed method might equally well be employed, as one can do it more easily and quickly.

It will be asked, How can this method of tying a knot accelerate the operation? Take, for instance, a breast case where there are twenty or more artery forceps applied and waiting for ligatures. A reel of catgut is taken in the right hand, its end passed round the forceps held up by the house-surgeon, the knot tied with the left hand, and held by the left hand while the house-surgeon cuts it off; while he is doing this the right thumb and forefinger grasp the new end of the catgut; the left hand then casts off the useless portion, and the house-surgeon lifts up the next clamp, and the surgeon has the end of the suture in his fingers ready to pass round it.

The house-surgeon should keep his scissors in his right hand, and not put them down until all the ligatures are tied. With his left hand he should lift the clips and unfasten them. This requires a little practice, but after a time the whole of the combined manoeuvre goes on like a machine; there is no hurry, but time is saved, and one feels that the work is progressing favourably.

Then, in applying interrupted sutures, as in the closure of an abdominal wound, the combination of the use of the thimble with the ability to tie the one-handed knot helps immensely. The needle is driven through with the thimble and taken by the finger and thumb of the right hand; meanwhile the left hand takes hold of the end of the strand of gut and ties, the right hand keeping hold of the needle, which is then ready for the next suture. The left hand now takes the ends of the first knot and holds the skin taut for the introduction of the second stitch; the needle is passed for the second time and then cast off while the house-surgeon cuts the gut from the first suture. The gut is now not long enough to enable one again to tie the single-handed knot, so one proceeds as follows: The left hand is holding one end of the gut to be used for the second stitch and also the short piece cut from the first suture; this latter may be disregarded, and the first portion of the single-handed knot tied, the second part being tied by the right hand. In this way a little time is saved by not having to discard the cut portion of the first knot and pick up the end again for the second one; the waste portion from the first knot falls away automatically when the second is completed.

By proceeding in this way time is saved by not having to pick up the needle, which is not let go until it is finished with. Contrast this with the double-handed method: The needle is passed and then laid down while the knot is tied, and if all goes well it has now to be picked up again, which takes a little time. But it is not always so; while left to itself it not infrequently becomes unthreaded, or, what is still worse, it contrives to turn round and prick one's finger. By using the single-handed method the needle never leaves the fingers, and its point is therefore always under control until it is finished with. Further, the short end of the gut can be held between the third finger and the ball of the thumb, so that there is no likelihood of its becoming unthreaded. When facility has been obtained with the single-handed method quite 50 per cent. is gained in time by its use, and this amounts to something when one has a long wound—as after amputation of the breast—to close.

Further, when one is operating without an assistant, it is easy to place all the sutures in a long wound without having to use the scissors until the completion of the operation, when all the strands may be cut at once. Thus,

the first suture is applied as described and the strands held taut with the left hand while the second suture is applied. The needle is then unthreaded and the second knot tied with the right hand, leaving a loop connecting the two knots. This is repeated as often as required, and when the wound is closed the strands can all be rapidly cut off.

Here time is saved by not having to pick up and discard the scissors at every suture. Of course this is a very small point, but it is the small points which tell.

So much, then, for ligatures and sutures; now about the instruments for use during the operation.

The first point is to use as few instruments as possible; a large number in a tray only adds to the difficulty of finding any one required. For most operations a pair of dissecting forceps, one toothed ditto, a pair of straight scissors, a couple of scalpels, and six to ten artery clips and half a dozen needles will be all that need be used.

Needles.

As the needle has to be threaded, so it is important that it should have an eye sufficiently large compatible with strength. The next point is that it should not too readily become unthreaded. These two points are admirably met in the Pattison needle, which has a pear-shaped eye; the thread can be easily passed through the large part of the pear-shaped opening and then pulled down to the narrow portion, which grips the suture and prevents its slipping. This valuable device is a great time saver, and also a help to keeping one in a good temper. Nothing is so exasperating as for the needle to become unthreaded at a critical moment.

There are some needles on the market adapted for easy threading. One of these is the calyx-eyed, in which the thread is passed through a couple of slots. It is true that it is easily threaded, but it also often becomes unthreaded, the suture slipping out by the way it entered. This is an objection, but not the greatest. I do not use such a needle in a gastro-enterostomy, for instance, as the thread can so easily be partly sawn through at the calyx, and as the life of the patient is literally hanging on that thread for two or three days it behoves one to make sure that the thread is not weakened in any part.

There is another self-threading needle which was once on the market, but is now, for some reason, difficult to obtain. This has a slot in the eye, so that the thread can be passed through in the same way in which one attaches a watch to the hook at the end of the chain. This is a useful time-saving device, and is free from the objection of liability to saw through the suture.

I always use a straight needle if possible, as I can then be sure where the point is, and in driving a needle through any tissue which opposes a perceptible resistance the needle may rotate on its own axis. If it is straight the point is not deflected, but if curved the point describes an arc of a circle and often comes out in a different place from that intended. Moreover, with a straight needle the thimble can be employed and by it the point directed in any desired direction.

Scalpels.

Some years ago the advantages of a round-ended knife were pointed out by a surgeon in the South of England, but I am unable to give the reference. This scalpel is shaped like a dinner knife, and I have found it most useful. In dissecting out glands in the neck, for instance, there is no likelihood of pricking an unseen vein, as there is with the ordinary pattern. The round-ended knife can be used in cases in which scissors ordinarily would be used. Time spent in laying down the knife and taking up the scissors is saved. As an example, the opening of the abdomen in appendectomy may be taken. When the external oblique is exposed the blunt-ended scalpel can be used to cut a slot at the lower angle of the wound, and the knife then inserted edge upwards and the incision made through the fibres of the oblique, as with a scissors. There is no point to catch in the underlying muscle, and all goes smoothly.

Artery Clips and Scissors.

I much prefer the box joint, for it is more durable and the teeth of the clips are more accurately approximated. Those with take-off joints are so liable to fall in two when taken up, and nowadays, when boiling is universal for sterilizing instruments, the need for taking them to pieces

is not so obvious. Twenty years ago, when the dependence was on carbolic for disinfecting them, the take-off joint was a decided advantage.

It is well to have them made with large rings for the thumb and finger, so that they can be easily picked up and let go. When several artery clips, which have been used only as pressure forceps, are to be removed, there is no need to put each one down when it is released; three or four can be taken up one after the other, letting the rings slide up the fingers; then if the rings are large they can all be slipped off at once, thus saving a little time. There are some made with a little projection on each side near the handles, so that they do not lie flat on the table, but the rings are slightly lifted off it; the instrument is then more quickly picked up.

As an example, let us take the opening and closing of the abdomen for appendicitis by the gridiron method.

The incision is made through the skin with an ordinary scalpel, which is then laid aside and not used again, for aseptic reasons. A round-ended knife is then used to divide the subcutaneous fat. Any bleeding points are now secured and tied off in the manner already described. The skin wound is retracted by means of the thumb and second finger of the left hand, and the round-ended scalpel taken up again and not laid down until the peritoneum is reached; a slot is made through the fibres of the external oblique at the lower angle of the wound. Into this the knife is slipped and the aponeurosis slit up, then with the handle of the scalpel it is freed from its loose attachment to the underlying muscle. The wound in the external oblique is now retracted by means of the first two fingers of the left hand and the thin covering of the internal oblique divided; then, with the handle of the knife aided by the fingers of the left hand, the muscle fibres are separated down to the peritoneum. The knife is now laid aside, and a further separation effected by means of the two fingers of each hand. If the patient is a strong muscular man, or very fat, retractors may be needed to expose the peritoneum, but, as a rule, I find them unnecessary. The peritoneum is now picked up with a couple of pairs of clips and the opening made with scissors. The two clips are allowed to remain on, and with two others the upper and lower angles of the wound secured.

In closing the wound, the upper of these clips is taken in the left hand and a catgut suture passed with a straight needle and thimble and tied with the left hand, the right not letting go of the needle. The forceps is cast off with the left hand and peritoneum pulled up by means of the thread; the house-surgeon at the same time holds up the remainder with the three other clips and approximates the margins. It is now easy to pass an uninterrupted suture rapidly to the lower end of the wound, where it is tied off with the left hand, the right keeping hold of the needle. The same needle, which has not been laid down, now picks up the lower margin of the internal oblique at the anterior part of the wound, and is passed down the length of the opening in the muscle and the upper margin taken up; then a lace-like suture is applied and knotted off where the needle was first introduced. The aponeurosis of the external oblique is united by continuous suture, using a straight needle and thimble, and finally the skin sutures placed as already described.

The whole proceeding is done very rapidly, although there is no hurrying; each one of the trio knows exactly every little step that is to be made, so there is no confusion, and all goes perfectly smoothly.

The above was written some time ago and laid aside, but after reading the interesting paper on "Time in Surgery" by R. P. Rowlands in the BRITISH MEDICAL JOURNAL of April 15th, I am constrained to publish it in the hope that after such an able introduction to the subject as Rowlands has given, other surgeons may be induced to give some account of their own particular "fads" conducive to time saving at operations.

Its objects are the foundation of professorships and scholarships in the various medical schools of the United States and the maintenance of institutions for the treatment of sufferers from tuberculosis.

DRESSINGS USED IN A CASUALTY CLEARING STATION.

By A. DON, F.R.C.S., MAJOR R.A.M.C.(T.F.).

TEN months in a casualty clearing station gives one an opportunity of trying the various methods of dressing wounds as they have been from time to time suggested, and of comparing their efficacy in cleaning damaged tissues, in preventing the spread of infections, and in adding to the comfort of the patients. If, as happens in my case, the surgeon is not identified with any of the newer disinfectants, a fair trial may be assured for each of them. The surgery of wounds, as distinct from the method of dressing, is not meantime under consideration, but it must be stipulated that, for real comparison, the surgical technique should not change coincidentally with the method of dressing. To change both at the same time introduces two factors, either of which may alter the whole picture.

In published writings on the treatment of wounds in the present war one meets with assertions that antiseptics have failed us; that previous experience in, say, South Africa, does not help us; and even the suggestion that the dressing of wounds is more the province of the physician than of the surgeon; and, further, that all previous knowledge of the treatment of wounds must be a bar to success out here. Such statements must be taken *cum grano salis*, even though the writers are experienced and men of note.

It is true that a surgeon's methods in civil practice become more or less stereotyped. Older men unlearn old methods with difficulty and assimilate new ones with diffidence, but one is still left with the feeling that the surgeon of experience who possesses the virility to be at the front is a valuable asset to the army. His civilian dogmas get a rude shock at first, and his confidence in his well-tried methods may be shaken, but he soon recognizes the new elements he has to contend with, and will certainly have met them before, if rarely or at least will be familiar with most of them from his knowledge of the history of surgery. The fact is that it is merely his memory that needs refreshing, and his fixed habits that need reforming.

Few even of the older surgeons have seen hospital gangrene, and they do not always recognize that this serious scourge of surgery throve on a lack of scientific knowledge of bacteriology and antiseptics, which is now taught to and understood by every medical student. The present gas gangrene is identical with the old hospital gangrene, and the mixed infections we see so frequently were in olden times, as sometimes even now, introduced in the dressings themselves. The greater number of shell wounds, and the high-velocity rifle bullet at close range, produce effects that are of daily occurrence here, but were new at first to surgeons who had been through the South African campaign. But all these effects have been met with before, and are, in fact, matters of history.

The one new feature is the trench warfare, and its effects on wounds. The soldier's skin, clothing, hair, every part of him which a missile has to traverse, is covered with mud, which is carried to the depths of every wound. Highly fertilized soil may contain every conceivable pathogenic and putrefactive organism. Such germ-laden wounds are unusual in civil life, and were so also in the South African war. They are, however, met with in accidents from agricultural districts, which are admitted mostly to small provincial hospitals, though they are also seen by surgeons attached to medical schools. The badly damaged and dead tissues at once putrefy and smell badly, and their treatment becomes more a question of sanitary science than of modern surgery, and has been more successfully dealt with by the disinfectants used in sanitation than by the commoner surgical antiseptics. To get rid of the smell and putrefaction in the wound has been to get rid of the unusual in the disease. What is new, then, in the surgery of this campaign is old in sanitary science, and older still in the history of surgery, which, being the older science, had dealt with the grosser infections much earlier.

Among the many methods of dressing wounds one comes across, none are really new, but one recognizes many an old friend in new war paint, habilitated with elaborate word-painting more or less accurate and convincing. A dip

into a good textbook of surgery in use, say, about the early part of last century will convince any sceptic, though it is a thankless task to recommend such a perusal. The names of drugs are less mystifying, but a good description of the treatment of foul wounds with chlorine, iodine, and saline compounds, and even of gas gangrene itself, will be found and will well repay the ardent student. Attention has already been drawn to this by other writers. The cruder drugs produced then, as now, in a short time very candidly stated, a clean surface from which exuded laudable pus—that transition in the discharge from the nauseating putrefactive débris of decaying tissues to the odourless creamy pus, then, as now, considered laudable. This pus comes from living tissues in which are to be found the ordinary pyogenic germs alone. Putrefactive organisms can attack only dead tissues or those weakened by pyogenic processes or mechanical traumatism. To get rid of the putrefactive organisms and to prevent the ingress of the pyogenic has been the problem of wound treatment for surgeons in the present campaign, and it is yet to a great extent unsolved. Towards this objective I offer my experiences in a casualty clearing station.

I. Hypertonic Solutions.

Wright's saline treatment has received perhaps more praise than any other. In theory it seemed excellent, but in practice the results are various. When used properly and in suitable cases they are good, but the cases require careful selection, and its application requires more skilled watching than can usually be given with the means at one's disposal so near the front. The method and choice of cases cannot be left to the discretion of a dresser or even to the average medical man attached to a casualty clearing station, and if used as a routine dressing the results are more often positively bad than passably encouraging. In the majority of places where hypertonic salines are used as a routine dressing they are either too long continued for bad lacerations or are applied to many cases almost clean, where they are unsuitable.

To living tissues strong salt solution is extremely irritating, and causes pain for a very considerable period after each application. This does not depend on the patients. The action of salt on wounds was well known in history, when it used to be rubbed into the cuts made by the lash, not for its healing power but it noted. I have personally experienced its smart, for it was a favourite dressing in hypertonic solution in my boyhood. I owe the preservation of a perfect finger joint to its use, yet I well remember the happy change to a soap and sugar ointment which completed the treatment.

The hypertonic method does well for joints, when they have not been laid open too freely, and probably lacerated wounds where the explosive force of the missile has killed the tissues for a considerable distance beyond the bullet track. The salt preserves these dead tissues from putrefaction (a well-known use of salt), for it is an absolute bar to the growth of putrefactive organisms, while its irritating effect on the living tissues sets up a more or less severe discharge, which helps to prevent the ingress of pyogenic germs. But such a dressing should not be covered by non-permeable tissue, which will check entirely such outward flow of serum. The tabloid and gauze pack is perhaps the best for dirty wounds in casualty clearing stations, as it can be left for a considerable time without attention. There is at first practically no pain following its application, for even the tissues that will ultimately live are rendered analgesic by the blow. But once the dead tissue separates, and the hypertonic dressing becomes painful, it soon produces purplish, waterlogged, shining granulations, which at one and the same time form a barrier to the exit of discharges, and to any feeble antiseptic action it might exert on the cooped-up pyogenic germs below. Absorption begins, and abscesses in the depths are not unusual.

How often are these pyogenic organisms present from the start? I am inclined to believe that even nowadays they are sometimes introduced much as they were by the surgeons in pre-antiseptic days. I have seen in hospitals out here the pernicious habit, which had almost disappeared in the best civil hospitals, of wringing gauze from antiseptic solutions with the bare hand. The result is that all the germs present in the previously dressed cases, are inoculated into the wound. Rubber gloves

prevent this patient-to-patient infection, and when combined with the method I adopt of dressing all the serious cases myself and leaving the bandaging to an assistant, often an orderly, and washing the gloved hands well with a cotton-wool dab in a strong antiseptic after each case, time is saved and perfect safety from multiple infection is assured.

Before the wound shows the purplish granulations described, and before the patient complains of the smarting, and in all wounds where the exposed surfaces are living tissues, hypertonic solutions are contraindicated. The saline method of Wright requires careful watching by the surgical specialist, who must see every case so dressed daily. It is not, therefore, suitable for routine work in a casualty clearing station, nor even in a base hospital. I have said nothing of the normal saline, with which everyone is familiar.

II. Hypochlorous Acid.

Hypochlorous acid has been used in the forms *eusol* and *eupad*. The deodorizing effect is sometimes magical, especially when the dry *eupad* is applied to stinking, bruised, and dead tissues. But *eupad* so used is very caustic and very painful, and should only be applied by the surgeon himself. *Eusol* solution, on the other hand, is seldom painful, and is a good routine application, but some skins are very susceptible to it, and it must not be applied for long periods to wounds of the back of the hand, dorsum of foot, and of the neck, forearm, and wrist. It should always be freshly mixed, applied once or exceptionally twice daily, and should not be covered by protective. The drip method is specially useful in compound fractures, and in all lacerated wounds of the limbs where there is gas gangrene and foul smelling sores. *Eusol* is one of the best methods we have tried, and it need not be continued after the wound is fairly clean and free from smell. A sterile dressing is then quite sufficient.

III. Iodine.

Iodine in spirit or watery solution acts pretty much like hypochlorous solutions as a deodorant, while the spirit preparations act like the hypertonic salines, by inducing a serous flow. Iodine is very irritating to most skins, and the pain continues for some time after the dressing is applied.

IV. Spirit: Glycerine.

Methylated spirit or glycerine, alone or charged with antiseptics—for example, biniodide spirit, glycerine and ichthylol—both act like the hypertonic saline in producing free discharge, and require frequent changing. They do not cause so much pain, but are expensive to use in routine work.

V. Carbolic Acid.

Carbolic acid, when used pure, canterizes the surface, and is only feebly antiseptic, as its combination with albumin dams back all discharges. It is a useless application where there is deep destruction of tissue. It runs over and destroys the skin, and cannot be recommended as a first treatment for wounds of any kind. In solutions of 1 in 60 on double cyanide gauze it is quite good in a rush. Large quantities of the gauze can be kept moist in this solution in small enamelled *marmites*, as recommended to me by Colonel Wallace, and this method is specially useful in busy times. It is painless, can be applied to most wounds indiscriminately, and the dressing can be left entirely to nurses and even to orderlies in emergencies without risk. But carbolic is a weak destroyer of putrefactive organisms. The greatest danger in its application is the wringing of the gauze with the bare hand; this can be avoided by gloves or by applying the dressing moist with sterile forceps.

VI. Sterile or Double Cyanide Gauze.

Dry sterile gauze or the double cyanide gauze are both quite good dressings for visibly clean wounds, and if removed by hydrogen peroxide when too adherent are suitable for dressing such cases, and convenient for rushes. They are safer than moist dressings when applied with the bare hand carelessly.

VII. Hydrogen Peroxide.

Hydrogen peroxide cleans a cavity or surface quickly, and is a good deodorant, but is not satisfactory as a wet

dressing applied on gauze. The under layers become clogged and non-absorbent. It is a weak antiseptic, which at once produces its total effect if thus applied. Like protective, it checks drainage of discharges and promotes absorption. Its mechanical effect is practically its only recommendation as a lotion for dressing. It is quite good as a bath for foul-smelling wounds, either alone or with boracic.

VIII. Continuous Irrigation.

I have not said much regarding continuous irrigation of wounds, as only exceptional cases in quiet times can be so treated in casualty clearing stations. This is especially true in a tented unit.

IX. Vaccines and Serums.

Injectations of polyvalent serum has seemed to do good in many cases, especially when used before an operation on a granulating wound where bone has to be removed or a plastic operation done. There is less local reaction and less general disturbance if a full twenty-four hours is allowed to elapse between the injection and the operation.

CONCLUSION.

It is not so much the antiseptic dressing used as its intelligent application that matters. Almost any one of the methods we have tried will give average good results, but there are cases in which one application is more suitable and more easily applied than any of the others, and it is right here, to use an Americanism, that the specialist in surgery in a casualty clearing station comes in. He should never become an enthusiast in any one method of dressing, as he is then a danger to his patients and an embarrassment to his colleagues, to whom freedom of choice is as necessary to secure their intelligent interest as a change of method of dressing may be to the patient. No surgeon or dresser in a casualty clearing station should try to drive a one-horse shay and so become a menace to the recovery of not a few of his patients.

ACUTE URINARY INFECTION WITH PARATYPHOID B BACILLUS.

BY

C. WORSTER-DROUGHT, M.B.CANTAB.,

TEMPORARY LIEUTENANT R.A.M.C.,

AND

ALEX. MILLS KENNEDY, M.D.GLASG.,

TEMPORARY LIEUTENANT R.A.M.C.,

BACTERIOLOGIST TO THE ROYAL HERBERT HOSPITAL, WOOLWICH.

It is now generally recognized that the differentiation between typhoid and paratyphoid fevers is a problem that can only with certainty be solved by the bacteriologist. It has been said that some distinction may be made clinically, in so far as cases of paratyphoid fever usually run a much milder course. Recently, however, several deaths from paratyphoid fever have been reported, and it is probable that this clinical distinction will prove unreliable; further, with the more detailed study of all febrile cases, it seems likely that anomalous forms of the latter will be recognized.

The case herein reported illustrates acute urinary infection with the *B. paratyphosus* B, and, while exhibiting little in common with ordinary paratyphoid infection as hitherto recognized, presents several additional interesting features worthy of record.

The patient, a private in the A.S.C., aged 17, was admitted to hospital on December 31st, 1915, for "abdominal pain and incontinence of urine." He had had no previous illnesses, and had never been abroad. He was quite well up till the morning before admission, when he was seized with intense and frequent desire to micturate, but was unable to pass more than a small quantity of urine at frequent intervals. This condition persisted throughout the day, and he experienced a certain amount of pain across the lower part of the abdomen. During the night he was unable to sleep, and felt "shivery." The following day the abdominal pain was rather more severe, and the slightest desire to micturate was always associated with inability to control the flow. There was no vomiting, no diarrhoea, and he complained of only slight headache.

On admission, the skin was hot and dry, the tongue very furred, the temperature 103° F., and the pulse 112. There was some tenderness in the region of the bladder, but nowhere else in the abdomen, and a quantity of albumin was found on

examination of a catheter specimen of urine. Nothing could be made out in any of the other viscera, the heart and lungs were normal, and the spleen was not enlarged. The next day (January 1st) the patient was rather drowsy, incontinence of urine was present, and a specimen, on standing, showed quite an appreciable deposit of pus.

The patient's condition remained much about the same until January 6th, on which date bladder control was regained although frequency of micturition continued and pus was still present in the urine. There was some diarrhoea on January 5th only, but at no other time. On January 8th a small quantity of blood appeared in the urine and persisted until January 12th; but the pus persisted in considerable quantity until January 17th, when it was noticed to be very much diminished. On this latter date a few hyaline casts were observed.

On January 1st the patient was placed on treatment with the following mixture, which was continued three times daily throughout the illness:—Hexamine gr. x, sodii acid. phosph. gr. xv, syr. aurantii 3i, aq. ad 5i.

On January 3rd *B. paratyphosus B* was recovered from the urine in pure culture; it gave the usual sugar reactions and agglutinated strongly only with a specific paratyphoid B agglutinating serum. The same organism was again isolated from the urine in pure culture on January 10th. A blood culture on January 5th proved negative.

A vaccine was prepared from the *B. paratyphosus B* recovered from the urine, and on January 11th an initial dose of 50 million was administered. On January 13th the agglutination reaction of the patient's serum against his own *B. paratyphosus B* was tested, using the macroscopic method, and a completely positive result was obtained up to a dilution of 1 in 100. On January 12th *B. paratyphosus B* was again recovered from the urine in pure culture. By January 12th the patient was free from pain and stated he felt much better. On January 16th 100 million of the autogenous vaccine were given as a second dose, and on the following day it was noticeable that the amount of pus in the urine was enormously diminished.

There was continuous fever from the onset up to January 7th, the temperature varying from 104° F. to 101° F., and from January 7th to January 15th there was an habitual evening rise to 100°–101°, although the morning temperature was normal. From January 16th onwards the temperature remained normal. The pulse-rate varied with the temperature. During the first three days it ran between 100 and 120 per minute, then tended to be a little slower, and on January 7th it varied between 80 and 90. From January 7th to January 15th the pulse ran between 80 and 100, on three occasions only going beyond 100. From January 16th onwards the pulse varied between normal and 100, surpassing this limit on only nine occasions.

On January 18th no paratyphoid B or other organisms could be recovered from the urine, and no pus cells were observed on microscopical examination. On January 20th tenderness over the bladder had disappeared, frequency of micturition had gone, and the patient felt quite well; a very faint cloud of albumin only was present in the urine.

On January 22nd we again failed to recover any organisms from the urine, but a few pus cells were seen on microscopical examination of the centrifugized deposit. On January 23rd the third dose of vaccine was given—namely, 250 million. On the 27th a trace of pus could still be made out in the urine, and on the 29th a 500 million dose of vaccine was administered. On February 1st a slight local reaction to the vaccine was noticed for the first time, and the patient's serum was found to completely agglutinate his own *B. paratyphosus B* in dilutions up to 1 in 400. On February 5th no organisms could be recovered from the urine, and a fifth dose of vaccine, consisting of 750 million, was given. On February 13th 1,000 million of vaccine were given as a sixth dose, and on this date the urine was found to be free from albumin, although a few pus cells could still be detected. On the following day bacteriological examination of the urine failed to show any organisms.

On February 20th the urine was still free from albumin, and no pus cells could be detected whatsoever. On February 24th the seventh and last dose of vaccine was given, namely, 1,500 million. On March 10th a careful search was made of the urine and only a few degenerate bladder epithelial cells were found after centrifugalization. No pus cells or organisms were seen, and cultures proved sterile. The patient, perfectly well, left hospital on this date for a convalescent home.

The faeces were examined bacteriologically on February 22nd, March 1st, 5th, and 14th, but on no occasion was the *B. paratyphosus B* or other member of the typhoid group recovered.

The infection in this case appears to have chiefly affected the bladder, although one cannot exclude an associated pyelitis which possibly was also present, but in a considerably slighter degree. The onset of the illness in its suddenness resembled ordinary paratyphoid fever, and in which "a feeling of chilliness is also common."¹ Apart from the localization of the infection the present case was markedly atypical in other respects. The pulse was not relatively slow (80 per cent. of cases), but was increased in rate in proportion to the rise in temperature; the spleen was at no time enlarged (50 per cent. of cases); there were no "spots" during the course of the illness (75 per cent. of cases), and no vomiting or abdominal tenderness beyond the early tenderness over the hypogastrium. In typical

paratyphoid fever diarrhoea is common during the first second, and third days, and it is a striking feature of our case that diarrhoea should not have occurred until the sixth day and then ceased on the day following.

It has been observed that in certain cases the *B. paratyphosus B* shows a marked tendency to pus formation; thus, among the purulent infections described are splenic abscess, suppurative orchitis, empyema, liver abscess, lung abscess, and peritonitis without perforation.² All these conditions, however, occurred following, or as a complication of more or less typical attacks of paratyphoid fever. H. Robinson,³ in commenting on a long series of paratyphoid cases, mentions, among complications, the fact that cystitis occurred once, and in this case *Bacillus paratyphosus A* was isolated from the urine. Stolkind,⁴ who is convinced that paratyphoid as well as typhoid infections are symptom-complexes, also states that cases of infection of separate organs have been met with—for example, appendicitis paratyphosa, cystitis paratyphosa, etc. He also describes, *inter alia*, an influenzal or respiratory form, but even in these cases the patients seem to show a large spleen and "spots."

It would appear, further, from a perusal of the literature, that it is by no means common to find paratyphoid bacilli in the urine during the course of an ordinary attack of paratyphoid fever. Fortescue-Brickdale,⁵ Dawson and Whittington,⁶ and others mention cases, but references are not numerous. As far as we are aware, urinary carriers of *Bacillus paratyphosus B*—that is, the bacillus occurring in the urine of otherwise healthy subjects—have not yet been reported. Wiltshire,⁷ in an examination of 98 cases of paratyphoid fever, says: "Kidney and bladder complications were very rare. In many cases . . . the urine was examined carefully for possible renal complications, always with negative results." Incontinence, apart from pyuria, sometimes occurs in severe paratyphoid, and was present in a few of Willcox's cases.¹

In connexion with our case it is interesting to recollect that in urinary carriers of typhoid the *B. typhosus* has its habitat generally in the renal pelvis, which is usually chronically inflamed, and it has also a secondary habitat in the chronically inflamed bladder.⁸ In fatal cases of typhoid fever the renal pelvis is often found congested, but the ureters and bladder are usually normal, though signs of cystitis may be found at times. In contrast to paratyphoid, bacilluria occurs in about one-third the cases of typhoid, although pyuria is recognized as a rare complication. Pyelitis sometimes occurs (Osler), and Patrick⁹ has recorded one fatal case of typhoid in which multiple abscesses were found in the kidneys *post mortem*.

In conclusion, to summarize the chief features in the case recorded above, we note:

1. Pyuria due to a pure infection with *B. paratyphosus B*.
2. The absence of the usual signs of paratyphoid fever.
3. The successful treatment with autogenous vaccine and hexamine.
4. The patient had not been abroad.

A CASE OF GANGLIO-NEUROMA OF THE SYMPATHETIC.

By DAVID RUTHERFORD ADAMS, M.D.,
ASSISTANT SURGEON, KILMARNOCK INFIRMARY.

ABOUT six cases of ganglio-neuroma have been recorded in Great Britain.¹ The history of this case is as follows:

A well-developed male child, aged 3 years, was admitted to Kilmarnock Infirmary on October 2nd as a case of acute intestinal obstruction from intussusception.

Twenty-four hours previous to admission he began to complain of severe pain in the abdomen, which was observed to be swollen and hard. Blood and mucus, with a small quantity of faeces, were passed several times by

the bowel. His condition was ascribed to a known indiscretion in diet. He had had no previous illness.

On admission the child looked ill and was very restless. The temperature was 104° F., pulse 160, and respirations 36. The abdomen was freely palpable. A swelling could be felt occupying the right iliac and right hypochondriac regions. It was immovable, very hard, and apparently circumscribed. Although the outline of the mass could not be entirely determined, the tumour appeared to be adherent along its deep surface, while the abdominal wall was freely movable over it. On palpation the whole mass seemed to be smooth, and of the size and shape of a large orange. A provisional diagnosis of sarcoma or of tuberculous glands was made.

The following morning laparotomy was performed. The abdomen was tense. The intestines were nowhere adherent, the ileum and part of the ascending, the transverse, and the descending colon were very red and inflamed, and about 6 in. of the ileum was collapsed, apparently from pressure. There was no farther sign which might have indicated a previous intussusception, and acute colitis was evident.

Behind the intestines, and pushing them over to the right and down into the pelvis, a large mass was found situated retroperitoneally along the right side of the bodies of the last four lumbar vertebrae, with the external iliac artery and vein crossing it superficially. The psoas muscle was behind the tumour and it appeared to be flattened. The tumour was immovable, and firmly adherent along its central and posterior surfaces; it was not adherent to the aorta. The condition was thought to be due to a sarcoma arising from the periosteum of the bodies of the vertebrae. A wedge-shaped piece was taken out of the substance of the growth for microscopical examination; a considerable amount of haemorrhage took place from the wound thus formed.

The child died the following day. The tumour was easily removed *post mortem*, it being apparently capsulated and only bound down by connective tissue to the sheath of the psoas muscle. No glandular involvement could be made out, and the kidneys and suprarenals were free from any implication in the tumour growth.

The tumour was kidney-shaped and rather flattened on its deep and central surfaces. Its length was 11 cm., breadth 9 cm., thickness 7 cm., and its weight 226.8 grams. The general appearance of the tumour was very like that of a fibromyoma. On section there was seen to be a very definite fibrous capsule. The substance of the tumour was firm, tough, and resilient. The cut surface was smooth and in some places glistening. White, grey, and yellow fibres could be distinguished in a general felted mass.

Microscopical sections were stained with the usual stains and also for axis cylinders, myelin, Nissl's bodies, fat and glia. It was easy to recognize that the great mass of the tumour was composed of nerve fibres supported in a fibrous tissue stroma. Both medullated and non-medullated nerve fibres were present. Large numbers of ganglion cells, similar to those of normal sympathetic ganglia, were seen in groups scattered throughout the growth. There were also many developmentally early ganglion cells, the so called sympathoblasts. The growth was non-malignant, and there was no metastasis.

I have to thank my chief, Dr. W. McAlister, for permission to publish this case.

SIR WILLIAM TURNER, Vice-Chancellor and Principal of the University of Edinburgh, left personal estate in the United Kingdom valued at £71,467, of which £33,730 is in Scotland.

In the summer term of 1914, the last academic peace term, there were 4,750 foreign students attending the German universities. In the summer term of 1915 this figure had fallen to 1,305, owing, as is alleged, mainly to the expulsion of about 2,600 students from hostile countries. It is, however, claimed that even in 1915 there were 62 Russians, 2 British, 5 Italians, and 1 Belgian students resident in Germany. Among the foreign students were 150 women.

THE THERAPEUTIC VALUE OF HYPOCHLOROUS ACID.

BY

RAÚL FLORES CORDOVA, M.D. LIMA.

(From the Lister Institute of Preventive Medicine, London.)

In October of last year I communicated to the *BRITISH MEDICAL JOURNAL*¹ some experiments on the neutralizing effects of hypochlorous acid on diphtheria toxin, and drew attention to the resistance the animal body offers to large quantities of the solution used.

During the last nine months various investigators have dealt with the hypochlorites as antiseptics—Lorrain Smith, Murray Drennan, Rettie and Campbell,² Dakin,³ Schütze⁴—and also given the results of treatment by intravenous injection—Lorrain Smith, Ritchie and Rettie,⁵ and Brand and Keith,⁶ in cases of puerperal infections; Fraser and Bates,⁷ in cases of toxæmia consequent to gas gangrene.

In this paper I publish further and more detailed experiments to determine the antitoxic and antiseptic power of hypochlorous acid *in vivo*.

It has been shown by Dakin³ that *in vitro* staphylococci suspended in saline are killed within two hours by sodium hypochlorite, 1 in 500,000, but that when serum is present a concentration of 1 in 1,500 is needed.

It has been thought, therefore, important to prove experimentally (1) which is the highest concentration of HClO tolerated by animals, and (2) what is the lowest concentration producing an antiseptic or antitoxic effect.

Rabbits of about 2 kilos in weight and therefore with approximately 90 c.cm. blood were used. The HClO solution employed was ensol with a hypochlorous acid concentration of 0.5 per cent, physiological saline being used in place of water and CaCl₂ added on account of its antitoxic properties; it is prepared as follows:

To 800 c.cm. physiological saline add 10 grams bleaching powder and 10 grams boric acid, shake vigorously, allow to stand for two or three hours, then filter and add to the filtrate 2 grams of chemically pure calcium chloride. The solution now contains HClO in a strength of between 0.5 and 0.6 per cent; saline is added until the required concentration of 0.5 per cent is reached. Owing to its instability the solution must not be used longer than three days after preparation.

While 20 c.cm. of this HClO solution, giving a concentration of about 1 in 1,100 in the blood of the animal, were generally well tolerated, 10 c.cm. proved to be entirely harmless, and the concentration of about 1 in 2,000 that resulted appeared, moreover, to be near the limit of efficiency; 5 c.cm. doses (about 1 in 3,800) seldom led to beneficial results.

Attention may be drawn to the fact that a great number of toxins of bacterial origin are considered to be of an albuminoid nature (Brieger and Fraenkel,⁸ Brieger and Boer,⁹ Etienne Burnet¹⁰); it is possible, therefore, that hypochlorous acid may neutralize toxins by coagulating and eventually precipitating them.

The following tables show the efficacy of 10 c.cm. doses of the HClO solution in certain artificially produced infections and toxæmias.

TABLE I.—Diphtheria Toxin.

6	100 "	10 c.cm.	—	10 c.cm.	Healthy.
Control	100 "	—	—	—	Dead after 48 hrs.

CONCLUSIONS.

It has been found that in rabbits 10 c.cm. intravenous doses of a 0.5 per cent. HCIO solution, even when repeated on two or three days in succession, produce no ill effects, that they may delay or prevent the onset of symptoms due to the injection of the animals with diphtheria and tetanus toxins, and with cultures of *Bacillus perfringens* and *Staphylococcus pyogenes aureus*, the rabbits recovering from the infection or remaining healthy.

Hypochlorous acid intravenously administered is therefore to be regarded as of therapeutic value; the antiseptic apparently delays the development of bacteria and destroys their toxins, thus enabling the natural resistance of the animal to assert itself.

It is suggested that this destruction of toxins may be in the nature of a protein coagulation.

A SIMPLE METHOD FOR THE INTRAVENOUS INJECTION OF EUSOL.

BY

JAMES M. GRAHAM, M.B., F.R.C.S.Ed.,

INTERIM ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH;
ASSISTANT SURGEON, DEACONESS HOSPITAL, EDINBURGH.

THE intravenous injection of eusol has been recommended by Lorrain Smith, Ritchie, and Rettie¹ to combat the toxæmia in cases of septic infection. Encouraging results have been recorded,² and the method of treatment has opened up a new field of investigation. The object of this note is to describe a simple method of injecting the solution by means of a syringe and needle. It is preferable to introduce the solution without exposing the vein by incision, as the patient is less disturbed by the simpler procedure, and it may be necessary to repeat the injection several times. It is further of advantage to employ a syringe rather than a funnel and tubing attachment to the needle, as the rate of injection can thereby be more readily controlled.

A 20 c.cm. Record syringe, is of suitable size, but the capacity of the syringe is not important. To avoid the necessity of detaching the syringe from the needle, for the purpose of refilling, a simple two-way cannula is employed fitted with a stopcock. The ends of the cannula are moulded to fit easily but firmly on to the syringe at (c) and to the needle at (A). A lateral

Syringe, cannula and needle for intravenous injection of eusol.

opening is placed at (B) and connected by rubber tubing to the flask containing the solution of eusol. By turning the stopcock the syringe can be connected either with the needle, as seen in the diagram, or with the eusol solution by means of the lateral opening. It is best to use a fine needle, as the rate of injection should be slow—usually about 10 c.cm. in one minute. In the case of small veins also a fine needle is more likely to penetrate the wall of the vein successfully. If the needle is slightly bent, as seen in the diagram, there is less chance of puncturing the vein a second time. A superficial vein in front of the elbow is usually available. If there be difficulty in finding a suitable vein, the patient should be kept in a warm atmosphere for some time before the injection. In cases where no vein can be demonstrated, even with a tourniquet, the arm should be placed for a few minutes in a hot-air or hot-water bath.

Before insertion the needle should be attached to the cannula and the cannula to the syringe, so that the entire apparatus is rigid and easily controlled. There should be a few cubic centimetres of saline in the syringe, and after puncturing the vein the plunger should be slightly withdrawn; if the vein has been successfully entered, a stream of blood will be drawn into the syringe. The saline within

the syringe should be injected next, in order to make certain that there is no leak. The stopcock is now turned and the syringe filled by withdrawing the plunger. After reversing the stopcock, the eusol is slowly injected into the vein. This process is repeated till the desired amount is injected. At the conclusion a syringe of saline should be introduced. The initial dose should be from 50 to 100 c.cm., but later as much as 150 c.cm. may be given. Care must be taken not to inject any eusol into the tissues, as even a few drops will cause severe pain.

The solution injected is eusol, to which common salt has been added in the proportion of 8.5 grams per litre. It is prepared by shaking up 25 grams of a mixture of equal parts of chloride of lime and boric acid in 1 litre of water and subsequently filtering; to the filtrate 8.5 grams of common salt are added. Before injection the solution of eusol should be warmed to about the blood temperature by placing the containing flask in a basin of hot water.

It is important to note that it is essential to adhere strictly to the directions given for the preparation of eusol, which is a balanced mixture containing about 0.5 per cent. hypochlorous acid and 1.2 per cent. calcium borate.³ The presence of the borate gives the solution a reaction faintly alkaline to litmus.

It has already been pointed out that it is impossible to inject either free hypochlorous acid alone or solutions of sodium hypochlorite.⁴

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN UNUSUAL CASE OF MUMPS.

Miss McC., aged 22, a student at a physical training college, returned from Scotland on January 27th, 1912. On January 29th she gave a lesson in a school where mumps had been prevalent for several weeks. On February 1st she was skating for several hours. During that night she was seized with vomiting and acute abdominal pain. The vomiting ceased by the morning, but the pain remained, and was treated by hot fomentations. I saw her first on the morning of February 3rd. She then complained of considerable abdominal pain about two inches above the umbilicus. The abdomen was rigid and flat; the temperature was 102°, and the pulse 100. There was a history of constipation. She was given one ounce of castor oil and the hot fomentations were continued. By the evening her bowels had acted four times, and some scybalous masses had passed. The pain was now referred to the region of the descending colon, which appeared to have still some hardened faecal masses in it. She was given a simple enema, which acted well, more scybala passing. The pain then passed to the left ovarian region, where it remained till the evening of February 6th, when the temperature, which had kept between 100° and 102°, dropped to normal; on February 7th it again rose to 101°, and she had pain to the right of the middle line over the right ovarian region. This pain continued, and on February 9th there was fullness and dullness over its seat; this increased, and on the morning of February 11th Mr. Gifford Nash saw the patient with me. He found the lower part of the abdomen doughy and oedematous, with rigidity of the abdominal muscles. By digital examination the rectum was found to be ballooned and considerable exudation round it. She was removed to the nursing home for observation.

On the morning of February 12th both parotid glands showed the typical swelling of mumps, the fullness of the abdomen was less, and the tenderness considerably diminished. By February 21st the patient was convalescent, all parotid swelling had gone, and also the fullness and tenderness from the abdomen. From the sequence of events, it would appear that the pancreas was first affected, then the left ovary, after that the right ovary, and finally both parotids simultaneously.

There is no history of the patient being exposed to infection before her return here. Is it possible that she

received the infection on January 29th when teaching in the infected school? Fourteen to twenty days is the usual incubation period for mumps according to most writers, but Fagge in his book says from six to twenty-one days.

I wish to express my gratitude to Mr. Gifford Nash for his kind advice and valuable assistance in this rather puzzling case.

ANDREW CHILLINGWORTH, L.R.C.P.Ed.,
M.R.C.S.Eng.

Bedford.

AVULSION OF THE DISTAL PHALANX OF THE THUMB.

A DRIVER of the A.S.C. was exercising a mule when the animal bolted, and the man was thrown off his feet and dragged, owing to the fact that his right thumb in a woollen glove had been caught in a small ring in the harness. A ditch chancing to cross the path the man dropped into it and came to a dead stop, with the result that the distal phalanx of the thumb, still clothed in the glove, cleanly severed, was torn off, carrying with it the tendon and belly of the flexor longus to a length of 9½ in.

ROBERT SCOTT, M.B.,
Temporary Lieutenant R.A.M.C.

THE TREATMENT OF SEPTICAEMIA BY "FIXATION ABSCESS."

(By J. D. SPEID SINCLAIR, M.B., Ch.B., Resident
Medical Officer.)

THE history of the following case is one of three months' duration, and so typical of septicaemia that I shall confine my remarks to the more salient features, without entering into the minute details of the course of the illness.

Mrs. L., aged 39, was admitted on October 19th, 1915, suffering from septicaemia following confinement a month previously. Physical examination was negative except for a slight presystolic murmur at the apex. There was no discharge from the vagina; the uterus was freely movable and normal in size. She complained of no pain, and no tenderness was elicited in the pelvis on vaginal examination.

Course.

The temperature ranged between 100° morning and 103° to 104° and sometimes 106° in the evening, accompanied by rigors, and so continued for two and a half months, in spite of treatment.

The usual methods of treatment, including antistreptococcic serum, and stock vaccine, were tried, but her condition remained unaltered.

As she was becoming progressively weaker I decided to try treatment by "fixation abscess." Turpentine (m 20) was injected under the skin below the angle of the right scapula. As this unfortunately caused considerable pain fomentations were applied every three hours. In forty-eight hours the injected area became red and swollen; on the third day after injection I detected slight fluctuation, and made an incision into the abscess, but very little pus exuded. Fomentations were continued and resulted in a copious discharge of thick pus, the patient meanwhile being more comfortable and comparatively free from pain. On the fourth day after incising the abscess a large slough was removed, and the temperature dropped to 99° and remained so for four days, when it went up to 102°, with a rigor. After the rigor the temperature became 99° and next day 98.4°. On the following day it rose to 104°, accompanied by a rigor, after which it became normal and remained so. She was discharged in due course perfectly well.

By this method of treatment the actual microbe responsible for the patient's infection is employed to stimulate the antibodies, a guarantee which cannot be given even with an autogenous vaccine.

Reports of Societies.

SHAKESPEARE AND MEDICINE.

At a meeting of the Medical Society of London held on May 1st, the President, Lieutenant-Colonel WILLIAM PASTEUR being in the chair, Sir STCLAIR THOMSON delivered the annual oration, choosing for his subject "Shakespeare and Medicine."

Sir STCLAIR THOMSON, in the course of his oration, said that in this tercentenary commemoration it was surely very right that our profession should pay its tribute of recognition to our greatest genius, for after the great poetical subjects of love, hate, ambition, and war, there were probably no matters so frequently dealt with by Shakespeare as those in which the medical profession was concerned. There was a special reason why the Medical Society of London should take a particular interest in the most many-sided man the world had ever known, for its library contained the only authentic record of his death. This was found in the Commonplace Book of the Rev. John Ward, vicar of Stratford-on-Avon, commenced thirty-two years after the poet's death. In one of the sixteen duodecimo volumes of this work appeared

Shakespeare, Drayton, and
Ben Jonson had a merry
meeting and it seems
drank too hard for
Shakespeare died of a
feavour there contracted.

There was no need to surmise that Shakespeare actually studied medicine, but there was abundant material to show that he had a knowledge and comprehension of it that was simply marvellous. We could appreciate and enjoy and benefit by all that poets had seen and written, without attributing to them prophetic or superhuman powers. So with the medical references in Shakespeare, the science of his medicine was decidedly of his own period, and, like all science, it had moved forward. His profound knowledge of human life and human nature remained and explained why he is, and must always be, one of our greatest masters of medicine. The mere references to various diseases, symptoms, drugs, and so forth need not be collected as remarkable evidence of the great poet's medical knowledge or insight. Sir StClair Thomson said he would refer to such matters and to Shakespeare's knowledge of contemporary medicine very briefly, and give more consideration to his astonishing acuteness of observation, his familiarity with the ways and thoughts of frail humanity, his discrimination of disease according to age, sex, and circumstances, his sensitive regard for our "brittle life," his sweet reasonableness and deep human sympathy, and his profound knowledge of that part of physiology and pathology which might be studied in the daily life of the street, the market, the tavern, the Court, the camp, or the home. These were subject to no errors of investigation; they were eternally true. The whole gamut of human life was epitomized by the humorously melancholy Jaques in twenty-eight pregnant lines.

The orator then spoke briefly of the state of medicine in the sixteenth century, and pointed out that Shakespeare, by the marriage of his eldest daughter, Susanna, with Dr. John Hall of Stratford, had plentiful opportunities for becoming acquainted with the life, habits, and ways of thought of a medical man and for picking up a fairly intimate knowledge of the practice of medicine 300 years ago.

Out of thirty-six plays medical characters were represented six times: (1) Dr. Caius in the *Merry Wives of Windsor*; (2) an English doctor, and (3) a Scottish doctor in *Macbeth*; (4) Dr. Butts in *Henry VIII*; (5) Cornelius in *Cymbeline*; and (6) the physician in *King Lear*. No character represented a surgeon. Dr. Caius was treated more as a figure of fun than as a regular physician, and it was probable that Shakespeare meant to represent a quack and not the learned Dr. Caius. Dr. Cornelius was possibly suggested by the famous physician of Charles V and simply adapted for dramatic purposes. The Dr. Butts represented in the fifth act of *Henry VIII* was no doubt Dr. William Butts, Fellow of Gonville Hall, Cambridge, and of the College of Physicians, who lies buried in

Fulham Church. Cornelius played with honour and astuteness a difficult part when the Queen asked him for poison, and the physician of King Lear played his part well and sympathetically. Cerimon in *Pericles* was both a physician and a nobleman, so that the good social status of the medical man was here accepted and illustrated. No nobler panegyric of our profession could be written than that put in the mouth of Cerimon.

Quacks, who flourished abundantly in the period, were portrayed in several plays. Among such characters were Pinch, Friar Lawrence, and Helena. Quacks and medical mountebanks were found in the earlier plays, and the first practitioner of medicine for whom Shakespeare did not entertain contempt was the physician in *King Lear*, which was written about 1606, the year before the poet's daughter married Dr. Hall.

Shakespeare showed an astonishing familiarity with many purely professional or technical matters, and manifested an intimate knowledge of the history of medicine. He employed medical terms which no ordinary playwright would know how to introduce. The diseases most frequently referred to were ague, rheumatism, plagues, pestilence, fever, measles, the sweat, and leprosy, but casual mention was made of many others. Their mere mention was of no moment; what should give us pause were the frequent flashes of genius which were revealed by the insight sometimes given of the appearances, character, and progress of the disease or of the patient. That the poet should so often ascribe mental characteristics to pathological states was surprising considering the age in which he lived. By quotations the orator illustrated Shakespeare's acquaintance with a deposit of lithates, the treatment of the *embonpoint* of success, digestion, chlorosis, goitre, epilepsy, crisis, and the well-known tests of life.

A large number of herbs and drugs and other preparations were mentioned by Shakespeare. What was of more striking and general interest was the evidence of the remarkably wise and reasonable views which Shakespeare manifested on the subjects of treatment, diet, and hygiene. He did not overestimate the help of medicine, and indicated the *vis medicatrix naturae*. He justified the custom of medical note taking. Music as a remedy, especially in mental states, was frequently mentioned.

Shakespeare's medicine reflected that of the period, for in his plays were found the doctrines held at that time. Such were the belief that our bodies consist of four elements—fire, air, earth, and water; the doctrine of "humours," and the view that plants possess peculiar powers if plucked at night, and during particular phases of the moon; the old beliefs in the influence of the planets on disease, and of the moon on the mind, and that toothache is caused by a humour or a worm. Even the quackery of his age was reflected in his pages—for example, that of water-casting. He was well acquainted with blood-letting—the practice of the period—and made frequent reference to the blood and circulation, though in the latter he naturally reflected the view which preceded Harvey's discovery.

The orator then, by many quotations, illustrated Shakespeare's knowledge of the voice, consumption, air and climate, syphilis, cancer, obstetrics, public health, mental diseases, surgery, and vivisection.

Shakespeare's deep sympathy with the tragedy of suffering shone out from every page of his plays. In his concluding section Sir StClair Thomson demonstrated the insight which the poet had into the influence of sympathy upon the patient, the relationship between hope and prognosis, the value of mirth and distraction, the virtues and evils of alcohol, the advantages and effects of abstinence, the horrors of insomnia and the benefits of sleep, the characteristics of our "sad humanity" as it falls into "the sere, the yellow leaf," and finally into the attributes of death.

Shakespeare's plays would be read by physicians when every medical treatise of the present year would have been completely eclipsed, and they would continue to be studied by future generations until "there shall be no more death, neither sorrow nor crying, neither shall there be any more pain."

Sir SIDNEY LEE, in proposing a vote of thanks to the orator, congratulated him on making a notable contribution to the celebration of the tercentenary. Mr. D'ARCY POWER, who seconded, said that the imperfect writing in

the poet's autograph suggested to him the effect of disease rather than of illiteracy, as some supposed.

The vote having been passed with acclamation, the meeting was adjourned.

There were displayed many exhibits which were related to Shakespeare and his time. These included some from the Wellcome Historical Medical Museum comprising *materia medica* mentioned in his plays, prints of medical men of the period, engraved portraits of Shakespeare, his house at Stratford-on-Avon, the Globe Theatre, and of a copy of the bust above his tomb, an enlarged photograph of a London apothecaries' shop of the period, oil paintings of a urine-caster and of blood-letting, portraits in oils of Sir William Butts and Dr. Caius, two London Delft pots used in Shakespeare's time, and a touch-piece and proclamation used in connexion with the royal cure of the King's evil. A selection of medical and surgical works from the library of the society, augmented by loans from the libraries of Dr. Lloyd Roberts, Dr. A. F. Voelcker, and Mr. D'Arcy Power, and from the Historical Medical Museum, was also on view. Other exhibits were a cross made from Shakespeare's crabtree, lent by Mr. D'Arcy Power; an unknown portrait of Shakespeare, lent by Dr. de Havilland Hall; medicine jars, lent by Dr. Mitchell Bruce; and bookplates of the Shakespeare Memorial Library from the collection of Mr. Bethell.

THE INFLUENCE OF ANAESTHETICS ON THE BODY TEMPERATURE.

At the annual general meeting of the Section of Anaesthetics of the Royal Society of Medicine on April 14th, the President, Dr. HAROLD LOW, in the chair, Dr. M. S. PEMBREY and Dr. F. E. SHIPWAY read a paper in which they pointed out that the influence of anaesthetics on the temperature might be exerted upon the loss of heat, the production of heat, or upon both of these processes. In man the practical methods of observation were the determination of the deep and surface temperatures, and, as a measure of the production of heat, the determination of the respiratory exchange. They had used the former method in man. Deep anaesthesia abolished the regulation of both the loss and production of heat, so that the response of the warm-blooded animal to external heat and cold resembled that seen in cold-blooded animals; a fall of external temperature diminished, a rise increased, the production of heat. It was this fact which complicated the problem. The internal temperature of a patient might show a fall, a rise, or no change, according to the conditions involved during the period of anaesthesia. A fall in the rectal temperature from 100° to 97° was within physiological range, when the whole extent of the daily variations in temperature was considered, but in the case of an anaesthetized patient subjected to an operation in a warm theatre (72° to 74° F.), such a fall might occur within one hour. During short operations of slight severity precautions against the loss of heat were not urgent, for in an adult there was, owing to the mass of the body, a reserve of heat not rapidly dissipated in a hot theatre. In such cases the advantages of warm ether as compared with cold might not be so apparent. On the other hand, in the case of a long operation or an operation upon a patient possessing low resistance the difference might be of great practical importance.

The authors had used an "open method," in which ether was dropped continuously on to two layers of domette or about twelve layers of gauze spread over a Schimmelbusch mask, which was so closely applied to the face that the whole of the respiratory current passed through the fabric on the mask. In the case of warm ether the end of the tube from the apparatus was placed under the mask and ether vapour pumped in just before each inspiration. The mask rested upon a shaped pad of flannel. With this method the temperature under the mask through which the patient breathed varied from 48.2° to 78.8° with cold ether, whereas with warm ether it was about 90°. A patient breathed about 5 litres of air per minute, and the expired air was raised to 96° or thereabouts. It was obvious, therefore, that more heat must be lost from the respiratory tract, although the expired air with cold ether might not be warmed to the same extent.

With such an "open method" they had never observed a lower temperature in the inspired air under the mask than 48.2°, the temperature of the air of the theatre being 77°, and they thought that some explanation was necessary for the exceedingly low temperature recorded by some observers. The air in the mask was being warmed constantly by the skin of the face and every few seconds by the expired air. For example, with a Schimmelbusch mask of two layers of domette and a pad placed over the face the temperature of the air was 91.4° to 93.2° five minutes after the mask had been placed over the face, the temperature of the room being 71.6° to 73.4°. The mask and pad were removed from the face and ether dropped upon the domette as during an administration; the temperature of the air fell to 32°; they were immediately placed over the face, and within one minute the temperature of the air rose to 61.7°. As regards the temperature of the body, observations of the rectal temperature were necessary. The surface temperature of the skin might rise under the influence of ether owing to dilatation of cutaneous vessels, and thus increase the loss of heat so much that the internal temperature fell. With warm ether the loss of heat from the skin could be more readily compensated. The excitability of the medulla was increased by a rise, diminished by a fall, in the internal temperature. This effect upon the respiratory centre was well known, and in a more pronounced form was seen in heat polypnoea or dyspnoea. The heart was stimulated by warmth, and the exchange of gases between the blood and the tissues was facilitated by a rise, delayed by a fall, in temperature.

A normal man reacted to external cold by diminishing his loss and increasing his production of heat. The anaesthetized man, paralysed for sensation and movement, had lost this control, and the level of the chemical changes which were a measure of vital activity could be maintained only by external warmth. This loss of control involved also the possibility of an abnormal rise in the temperature of the patient if he were exposed to excessive heat. A great practical advantage of warm ether was that it enabled the surgeon to operate in a cooler theatre; the ideal must be to keep the patient warm without exposing the staff to the depressing effect of high temperatures. Apart from diminished efficiency and endurance, a warm and moist atmosphere introduced the danger of the sweat of the surgeon undoing all the elaborate precautions taken to preserve aseptic conditions.

The "open method" was not strictly open. The mask and pad confined the air to a considerable extent. The dry and wet bulb thermometers recorded 88.7° and 85° under the mask, and varied in the air of the room 72.5° and 65.3°. The breath moistened the air; the amount of carbon dioxide might be 3 or 4 per cent. of the total 250 c.cm. of air under the mask; there was, according to the closeness with which the mask was applied and the thickness of the material, a certain amount of rebreathing, which might be an advantage when the stimulating effect of carbon dioxide was required.

Dr. SHIPWAY said he had used warm vapour anaesthesia for eighteen months. One part of the evidence in favour of the method had been given in the joint paper just read; the other part was due principally to some American anaesthetists, who had shown that warm vapours were safer, and diminished the loss of heat in the anaesthetized patient. He himself had found that anaesthesia could be pushed with warm vapours to a greater depth, and with less liability for respiration to become dangerously weak. The reason was physiological in that warmth increased the respiratory activity and stimulated the heart. Induction of anaesthesia was quicker and more quiet, respiration was calmer, since warm vapours were more readily absorbed and were less irritating. Shock was less; his results had been better with warm than with cold vapours.

A discussion followed.

THE late Sir Frederic William Hewitt left estate of the value of £35,378.

THE American Proctologic Society will hold its eighteenth annual meeting at Detroit, Mich., on June 12th and 13th under the presidency of Dr. T. Chittenden Hill of Boston. Among the communications to be presented are reports by Dr. Dwight H. Murray and by Dr. L. J. Hirschmann on the treatment of pruritus ani by autogenous vaccines.

Rebiewz.

ON MODERN METHODS OF TREATING FRACTURES.

THERE are movements—not to call them fashions—in surgery as in other spheres of human activity, and for a generation the thoughts and the ingenuity of surgeons have been turned mainly to the devising and perfecting of abdominal operations. The war has made the subject of fractures and injuries of joints very urgent on its practical side. Many new problems relating to complicated fractures are arising and the experience of civil practice has not afforded adequate opportunities for their solution. It has to be recognized that the immediate treatment of fractures in the war, not only of complicated fractures, whether compound or not, but also of simple fractures, calls for the adoption of procedures at the field ambulances which shall be then and there practicable, on a large scale, under the trying conditions which there exist, and with the means available, which are necessarily limited. It is true that when such cases reach the casualty clearing stations more complicated procedures may be feasible by way of operative interference not possible in the field ambulances, to say nothing of the first-aid posts. But, in deciding on any procedure to be undertaken at the casualty clearing station, the surgeon must have constantly in mind the practical questions which arise in regard to the safe transport of the wounded man to the base, and even beyond that point in hospital ships. With these practical considerations in mind, for they are essential elements of sound treatment in war, we sought guidance in Major Hey Groves's book *On Modern Methods of Treating Fractures*.¹ The position with regard to fractures is of urgent importance alike to the individual wounded soldier and to the nation, and on that account we cannot gloss over opinions which we believe to be erroneous, more especially when expressed by high authorities.

We regret to have to say that, in our opinion, formed after careful study of the book, Major Hey Groves does not express the British view of what is considered modern and best. The author shows evidence of having come under the influence of the German school; this in itself is no drawback, for it is well to try all things, but it is necessary to hold fast that which is good. The trouble is that the author does not seem to have mastered the teachings of the British school. This is doubly unfortunate, for one of the greatest geniuses of all countries in this particular branch of surgery was the late Mr. Hugh Owen Thomas, M.R.C.S., of Liverpool. A study—it must be close and very careful of details—of Thomas's methods would preserve for our country the reputation which Major Hey Groves seems disposed to give to Bardenheuer.

The non-operative treatment of Lucas-Championnière (massage) and the operative methods of Arbuthnot Lane are freely dealt with, but the prominence assigned to them is so great that the book fails to give a representation of British procedures applicable to conditions arising in the present war, or even to those which occur in civil practice in times of peace. From the operative point of view the methods of treatment described are not suitable for general adoption. From the non-operative point of view we doubt whether the views advocated are better than those referred to in the first chapter of the book, in which the practice of the surgeons of ancient Egypt is mentioned.

We will refer briefly to the views of the author upon one of the commonest of fractures—Colles's—as an illustration of failure to describe what we may call British practice of to-day. The treatment advocated (p. 28) for "a case of Colles's fracture of the usual variety with impaction and slight deformity. . . . For the moment it does not matter if the case is one of sprain, separated epiphysis, or fracture," is as follows: "The patient is to be seated opposite the surgeon and the hand gently taken in his and light massage applied. . . . The whole of the first séance lasts for about twenty minutes. . . . The arm is then lightly bandaged to a splint—of which Carr's is certainly the most comfortable. . . . Having arrived at

this stage, arrangements should be made to have an x-ray picture taken." When dealing with Colles's fracture "with much displacement of the fragment," the author writes: "In the first place, it is wise to be guided by one's estimate of displacement by the x rays rather than by examination of the hand." What is to happen to men who suffer in the wilds of Africa, the steppes of Russia, in the bogs of Ireland, the Highlands of Scotland, or in Wild Wales, from this very common fracture? "The replacement of the fragment . . . should be made only after the limb has been soothed and pain abolished, if possible, by the preliminary massage. If this has been highly successful, it may be possible in the hands of an expert to carry out the reduction with no other anaesthesia than that induced by the stroking. But for most practitioners, with whom the author would include himself, it is seldom possible to accomplish this sleight of hand, and recourse must be had to general anaesthesia" (p. 31). This quotation indicates a lack of acquaintance with the practice in Britain of those who have studied the epoch-making work of Hugh Owen Thomas. We would point out that the whole *séance* of reduction of the deformity and fixation of the damaged parts in suitable splints—the "setting of the bone"—takes as a rule less than one minute by the method advocated formerly by Thomas and now by Robert Jones.

As another illustration we may take what is said of the treatment of fractures of the femur by the splint which bears Thomas's name (pp. 57 and 58). Thomas's description is to be found in his book published about forty years ago, and attention has been prominently directed to it by correspondents and contributors in recent issues of the JOURNAL. Major Hey Groves suggests no fewer than five modifications of Thomas's splint, and does not think that even then it can be as efficient as his own wire cradle. The object of his modifications is to make Thomas's splint effective, but the views of those who have practical experience of that splint properly constructed and properly applied can best be stated by quoting the advice Thomas gave some forty years ago: "To the younger practitioners of surgery I would urge them to be adepts practically, before introducing alterations, which too frequently in the absence of experience must be either useless or injurious."

The illustrations of pathological conditions of bones given in the book are very good, and so are the models of surgical appliances for operative procedures. Most of the latter, we believe, will afford a curious study of the operative customs of modern peoples when the sedimentary deposit of this war is subjected to analysis by the future historian in search of the bed-rock. We feel rather confident that these relics will be either extremely localized or very sparsely diffused, and that the palaeontological place assigned to them will be on a shelf for fleeting fashions in modern methods of treating fractures.

JACOBSON'S OPERATIONS OF SURGERY.

It is probably to most people always more or less a matter of astonishment that in ordinary times so many books on medical science find their way into the market. It is something more than astonishment that fills the mind when we find the output little lessened in the midst of war. To issue a new edition of a world-famous book entails enormous labour on editors and publishers, if the work is to be maintained at its previous high standard of excellence both in matter and in form. This hard task has, we believe, been most successfully accomplished in the new edition of *The Operations of Surgery (Jacobson)*² by Messrs. ROWLANDS and TURNER. Let us say at once that the new "Jacobson" ranks easily first as the finest work in its subject in our own and probably in any other tongue. Books on operative surgery too frequently are hard, rigid—or shall we say cadaveric? Jacobson, above all things, is a living human book, whose sole interest is the welfare of the patient.

The work consists of two handsome volumes, creditable in every bibliographical sense to the well-known publishing house which issues them. In the first volume the operations on the head and neck, thorax, vertebral column, arm, and leg, are described; the second volume is devoted

¹ *On Modern Methods of Treating Fractures*. By E. W. Hey Groves, M.S., M.D., B.Sc.Lond., F.R.C.S.Eng. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd.; Toronto: The Macmillan Co. of Canada, Ltd. 1916. (Med. 8vo, pp. 298; 136 figures. 7s. 6d. net.)

² *The Operations of Surgery (Jacobson)*. By R. P. Rowlands, M.S.Lond., F.R.C.S.Eng., and P. Turner, B.Sc., M.S.Lond., F.R.C.S.Eng. In two volumes. Sixth edition. London: J. and A. Churchill. 1915. (Roy. 8vo, pp. 1040 and 940; figures 410 and 388. £2 10s. net.)

entirely to the operative work of the abdomen—this apparently unequal division of regions being demanded by the increased attention given in recent years to the latter branch of surgery. In the new edition the method of description of each operation followed in earlier editions has been preserved, and, indeed, extended. It is so characteristic that it is worth examining. Let us take, for example, the operation of removal of the breast. Before the actual description of the operative procedure is reached the authors have discussed important matters connected with it under these headings: (1) Indications; (2) results and dangers of the improved operation for removal of malignant disease of the breast; (3) local recurrence and the present-day extensive operations; (4) wide and thorough operation; (5) careful and judicious selection of cases; (6) continued frequent supervision of patients. Each of these points is fully entered into, the experience of all eminent operators narrated, and the permeation theory described and illustrated, not in a perfunctory, but in an educative and enlightening fashion. Then the operation itself is described step by step with diagrams and photographs, practical hints in technique, suggestions for the comfort of the patient, references, and footnotes, so that every conceivable difficulty is met. Whenever possible, especially in the interests of clear understanding, the actual words of an authority are quoted. Indeed, it is one of the eminently valuable features of the work that so many and such full literal quotations are made. It will readily be appreciated that when this method is adopted all through the two volumes Jacobson is much more than a textbook on operative surgery. Its title indicates the intentions of the original author to build a work in which the veritable manipulative part of surgery and its tools occupy a small place in comparison with the why and the wherefore and the when of a particular mode of treatment. In other words, it is primarily the interests of the patient that are in the heart of the authors, and they force that interest on the mind of the reader. The book is a philosophical and artistic yet eminently practical treatise on the operations of surgery.

Frankly we make no attempt to criticize in detail. We have carefully perused very many pages, and have been constantly impressed with the elaborate detail, the inclusiveness of every description, the adherence to reliable personal experience, the kindly acknowledgement of faults and mistakes, the friendly guidance to the young and less expert operator, the graceful, scholarly writing. Many features of the work project themselves before our minds, and one of the most prominent is the well-balanced sanity of view on disputed points. Two examples may be quoted: In discussing the operations of Harrison and Edebohlis for chronic nephritis, the authors say that consideration of the pathology of Bright's disease and the dangers incident to the operation do not lead them to expect from these operations more than may be looked for after judicious long-continued medical treatment. In considering the dire effects and heroic treatment of chronic intestinal stasis, lately so much discussed in England, no prejudice is raised, but several pages are given of verbatim quotation from the writings of Lane and others; yet withal the writer enunciates his own views with absolute clearness. "Personally I am unable to agree with his (Lane's) views concerning either the pathology or treatment of constipation. . . . Although Sir A. Lane's views do not seem to be supported by adequate proofs or to find much favour yet in this country they are certainly worthy of our serious consideration. Therefore I think it best to give his own words and illustrations." An unbiassed, unprejudiced outlook like this permeates the whole work.

Minor criticisms may be made on some small omissions. There is no mention of the frequent occurrence of the thick deposit of phosphatic debris on the edges of a suprapubic cystotomy wound and how to deal with it. We do not find the credit of first performing laparotomy for some forms of tuberculous peritonitis clearly allotted. It is our recollection, though we cannot find the original reference, that John Duncan of Edinburgh first advocated that form of treatment. Nor is there any mention of precise anatomical details in the method of injecting alcohol into the second and third divisions of the fifth nerve, though Harris's paper is referred to with the remark that the method is of value. We should have liked

a more exact statement as to the mode of applying the loop of jejunum to the posterior wall of stomach in posterior gastro-enterostomy—whether it shall be anti-peristaltic or iso-peristaltic—a point of real difficulty, in our judgement almost the only one in the operation. And last, we venture to think that more emphasis than mere mentioning might be laid on Macewen's method of controlling the abdominal aorta. The reviewer has done it himself on at least four occasions, and thinks that no other is worth mention.

A few instances have been observed in which the proof reading has slipped past blunders; these are, in volume i, middle of page 344, bottom of page 345, page 916, line 11; volume ii, page 476, references to figures wrongly made twice, page 699, eleventh line from top, and page 700, third line from bottom.

This, then, is a great work, a worthy exposition of a great art as it is practised by British surgeons (for, after all, the references to surgery outside the British empire are few in comparison with those inside). Not only are the authors to be highly complimented on producing it with such commanding success, but the surgical part of the profession is to be congratulated on the possession of such a treasure house of surgical learning and skill.

BOOKS ON CHEMISTRY.

For many years the student of physical chemistry has learnt to divide the properties of chemical substances into three groups in relation to their composition and structure. Some properties, such as weight, are termed "additive." Others depending only on the number of molecules concerned are termed "colligative"; gaseous volume, and the elevation of the boiling point or depression of the freezing point by substances in solution may be quoted as examples of colligative properties. Properties of the third group, depending on the arrangement of the atoms in the molecules of substances, and not merely upon their kind or number, are termed "constitutive"; and one of these, studied in the forties of last century by Kopp and elaborated by many chemists since his day, has recently been submitted to an elaborate reconsideration by Mr. G. LE BAS.^a He has written a highly technical account of the molecular volumes, that is, the volumes occupied by the molecular weights, of a great number of liquid chemical compounds. The value of such work lies in this—that careful study of the molecular volumes of organic and other compounds often enables deductions to be drawn as to the constitutions of their molecules, the ways in which the atoms are grouped therein, and often as to the valencies of the atoms concerned. In Kopp's hands molecular volume appeared to be an additive property; now that its partially constitutive character has been very thoroughly tested, its study becomes extremely helpful to the chemist. Mr. Le Bas's volume is filled with facts and figures, and comparatively little attention is given to the inferences to be drawn from them. The book is accordingly one for the advanced student of chemistry only, and to him it should prove both interesting and instructive.

The second edition of Mr. J. N. FRIEND's excellent book on valency^b has been brought up to date by the inclusion of many pages devoted to the theories of valency that have resulted from Sir J. J. Thomson's recent hypotheses as to atomic structure and electrons. The valency of an atom or element is defined as its power of fixing or combining with other atoms. From the chemical point of view it is quite the most important and characteristic property an element possesses. It has been the subject of unceasing study since the idea of an atomic attractive force (the modern "valency") was first clearly formulated by Frankland in 1852; before that time the conception of chemical affinity was inevitably vague, and could not be studied from the quantitative point of view for want of any clear conception of the differences between atoms and molecules. Yet for all this study our theories of valency are but

^a *The Molecular Volumes of Liquid Chemical Compounds from the Point of View of Kopp.* By G. Le Bas, B.Sc.Lond. Monographs of Inorganic and Physical Chemistry. Edited by A. Findlay, D.Sc. London: Longmans, Green and Co. 1915. (Med. 8vo, pp. 282. 7s. 6d. net.)

^b *The Theory of Valency.* By J. N. Friend, D.Sc.Birm., F.I.C. Second edition, revised. Textbooks of Physical Chemistry. Edited by Sir W. Ramsay, K.C.B., F.R.S. London: Longmans, Green and Co. 1915. (Cr. 8vo, pp. 206. 5s. net.)

slender growths of small heuristic value; they do not explain all the known facts, and they have led to singularly little in the way of research or discovery. There is good reason to believe that the problem of valency will ultimately be solved in terms of positive and negative electricity. Dr. Friend gives a thorough account of the history of the idea of chemical valency in his early chapters; the bulk of the book is occupied with the valency of the nine groups of elements in their periodic classification; the last fifty pages are given to the various physical, electronic, and electrochemical theories of valency. The text is clearly written, and demands from its readers no more than an elementary knowledge of physics and chemistry. Comparison with the only other book on the subject with which we are acquainted—namely, Hinrichsen's contribution to the chemical *Sammlung* of Ahrens, dated 1902—shows how greatly theoretical chemistry has profited during the last dozen years from the incursions of experimental physicists and electricians. Mr. Friend's volume may be warmly recommended to the attention of all who are interested in the progress of chemical science.

Mr. H. J. H. FENTON has recently written a little book⁵ intended to serve as a brief introductory outline of physical chemistry for fairly elementary students. The text covers the ground satisfactorily; it describes results rather than methods, detailing the views at present held, but rarely attempting to set out any of the experimental means or observations whereby such views have been reached. As a result there is a detached and academic air about the physical chemistry taught in this volume that makes the subject seem unreal or even dry; perhaps it is inevitable that this should be so. The book is designed for use in the study, not the laboratory.

A new *Textbook of Elementary Chemistry*,⁶ by Professor A. SMITH, makes a bold attempt, as the author says, to present the subject in a manner that is both rational and interesting. He thinks that while one sex will take especial interest in explosives, metallurgy, mortar, plaster, and cement, the other will be more attracted by plastics (from which hair-combs and artificial silk are made), starch, sugar, soap, and the digestion of foods. He attributes considerable importance to the work of the Russian author, statesman, and chemist, Lomonossov, in the middle third of the eighteenth century; but only makes incidental mention of so distinguished a chemist as Berzelius. The dry facts of inorganic chemistry are reduced to a minimum in the text; interest and colour are supplied by the inclusion of numerous economic or industrial details of the practical applications of chemistry to the arts and manufactures. How far a short elementary textbook constructed on these lines is capable of giving the student of chemistry a solid foundation on which to build is a matter that can only be settled by experience.

In the British edition of his small laboratory manual⁷ of elementary chemistry, designed as a companion to the textbook mentioned above, Professor A. SMITH sets out about a hundred practical exercises for the student. These vary in difficulty and complexity from the dissolving of caustic soda in water to the estimation of molecular weights by determination of depressions of freezing points. The text is brief and concise, and is abundantly interspersed with interrogation points to mark the moments at which the student should stop and make intelligent observations, or ask himself intelligent questions about the phenomena observed. Professor Smith undoubtedly covers a great deal of ground in his *Laboratory Outline*; the student who works through it will have every opportunity for acquiring a sound knowledge of practical chemistry.

Mr. W. M. HOOTON's brief manual of *Qualitative and Volumetric Analysis*,⁸ written for beginners in the science

of inorganic chemistry, gives a synoptic and tabular account of the reactions whereby metals and salts may be recognized and estimated by volumetric analysis. A certain number of the organic substances commonly met with are also taken into consideration; the rare metals are omitted from the general tables. The text has been cut down to a minimum, and is not self-explanatory; it is of a nature to appeal to the student's memory, and not to his intelligence. The use of such books is inevitable where but little time can be given to the study of chemistry; Mr. Hooton's volume is a good example of the class.

One of the platitudes of economics to which the study of industrial chemistry has given rise is that the prosperity of a country may be estimated by its consumption of sulphuric acid. A technological manual on *Sulphuric Acid and Sulphur Products*,⁹ recently published, estimates the world's annual production of the acid at seven or eight million tons; in Europe some four million tons are produced a year, the quantity having quadrupled since 1878. It is stated that the world's production of sulphur has been revolutionized by the discovery of vast subterranean beds of the pure element in Louisiana and Texas; the sulphur is extracted most ingeniously in the form of an emulsion by forcing down through iron pipes superheated steam which melts and mobilizes it, and compressed air which brings the emulsion to the surface. Dr. MARTIN and Major FOUCAR give numerous interesting details of the manufacture of sulphuric acid, sulphur dioxide, various sulphites, carbon disulphide, and hydrogen sulphide, which is employed for the purposes of chemical analysis and also in the manufacture of a few dyes. The book is unequal and sketchily written in places; it is well illustrated, and should be of interest to those who are concerned in any way in the subjects with which it deals. Numerous references to the literature are included.

NOTES ON BOOKS.

PROFESSOR PETER THOMPSON has recently printed eight papers¹⁰ representing part of the investigations carried out in the anatomical department of the University of Birmingham during the last few years. Several of these papers have appeared before, three in the *Journal of Anatomy and Physiology*. The book leads off with a full description, written and illustrated by the editor, of a human embryo 7 mm. in length, presumably twenty-six days of age, cut in serial sections 10 μ in thickness; this presents numerous points of interest to embryologists. Six of the papers deal with embryological subjects. The editor is to be congratulated on the general excellence of the book, which shows abundant evidence of the activity of research in the anatomical school over which he presides. The get-up of the volume and the illustrations are excellent.

The effort to set out the most recent theories of scientists and sciolists in forms readily intelligible to the layman is one that has always had an attraction of its own. We have before us three books¹¹ of popular psychology that are admirable examples of their type, well written, magisterial in style, but, so far as their contents go, of the nature of a Barmecide feast. In one of these volumes Dr. PUTNAM gives an account of *Human Motives*, from the point of view of medical psychology. Dr. CORIAT, in his book on *The Meaning of Dreams*, offers a popular description of psycho-analysis and interpretation on conservative and not unduly Freudian lines. Dr. BRUCE's book on *Sleep and Sleeplessness* presents a simple and rational account of the subject, and has the virtue of emphasizing the harmfulness of hypnotics as used by the layman.

⁵ *Physical Chemistry for Schools*. By H. J. H. Fenton, M.A., Sc.D., F.R.S. Cambridge: The University Press. 1916. (Cr. 8vo, pp. 223, 3s. 6d. net.)

INFANTILE MORTALITY AND THE RELATIVE VALUE OF MEASURES FOR ITS PREVENTION.

THE subject of the Milroy Lectures before the Royal College of Physicians of London was "Infantile mortality and the relative practical value of measures directed to its prevention."¹ The course was delivered by Dr. S. G. MOORE, who, as medical officer of health for Huddersfield, has had exceptional opportunities of appreciating the value of the various measures suggested, inasmuch as Huddersfield is a town which has been a pioneer in these matters.

The Infant's Right to Live.

In the early part of his first lecture Dr. Moore laid down the proposition that a child was born into the world possessed of certain elemental natural rights, quite apart and distinct from any legal right to property it might inherit. Every infant held these rights directly from those from whom it derived its being—that is to say, from its mother and father—and indirectly from the community or State into which it was born. The existence of its direct rights from its immediate parents did not nullify its indirect rights from the social organization as a whole. The infant had a right to a reasonable chance to survive to such an age-period that its own action might influence its destiny, and had a right, therefore, to a reasonable degree of protection from external influences which might imperil or destroy its life. Infant deaths from summer diarrhoea were practically absent from the returns in winter, but were numerous in summer. Infant deaths from bronchitis and pneumonia were practically absent from the returns in summer, but were numerous in winter. Therefore, Dr. Moore argued, in these forms death comes to infants from external conditions, and every infant had the inalienable right, held both from its parents and from the State, to be protected from these as well as from other external causes of death. He thought it necessary to lay down these propositions in order to oppose them to two doctrines which often found expression. One was, that as many infants were born to lives of misery, and would never do any good, they might be left to die. The other was that heredity counted much and environment little; that acquired characters were not transmitted, and that therefore most, if not all, of the labour in the field was vain.

Retrospect.

He then sketched the special work done in Huddersfield. First of all, in 1902-3, the reports of deaths from all causes were scrutinized with a view of selecting the disease, or group of diseases, likely to repay special preventive measures. Infant mortality was selected for five reasons: (1) The numbers of deaths of infants constituted so large a proportion of the total deaths, that any substantial reduction of the infant mortality figure would effect a material reduction of the general death-rate. (2) The causes of deaths of infants in quite a considerable proportion were manifestly preventable. (3) The lives to be saved were at the threshold of existence. (4) When an infant dies it is through no fault of its own; it appeals from its helplessness and its innocence. (5) The cost promised to be almost negligible. In 1904 a detailed report was presented to the sanitary authority, and in 1905 it approved a scheme of work against infant mortality, including the voluntary notification of births to the medical officer of health, and the visitation in their homes of all newly born infants immediately after birth by women doctors, followed by voluntary workers. The officials were informed that no inquiry would be made as to how many visits they paid. They were not to be in a hurry, but they were instructed to spare neither time nor effort in the endeavour to be sure before terminating the visit that the mother was instructed fully in the knowledge essential to the welfare of her offspring. Two forms of advice, "short" and "extended," were printed, and were to be left for the information of the mother.

In 1906 parliamentary powers were obtained requiring the notification of births to the M.O.H. In the following year Parliament passed an Act enabling every sanitary authority to require the notification of births, and in 1915

notification was made compulsory throughout England and Wales.

Dr. Moore then gave a summary of conclusions expressed in the reports of the medical officer to the Local Government Board on infant mortality. In commenting upon them, Dr. Moore said that the greatest service they rendered lay in pointing out that sickness and death in infancy meant sickness and death in later life *pari passu*, and continued as follows:

The demonstration of the existence of "blots" in good areas and of the existence side by side of areas of high and of low infant mortalities is of great significance. Not climate, nor topography, nor municipal sanitation, but the lives, the habits of the mothers in the homes, determine the difference.

I venture to express the opinion that throughout these conclusions too much importance is given to general measures. Because infant mortality is a part only of the general death-rate, and because it is a component thereof which presents special characteristics, particular action is needed for its elimination—procedure immediately directed against those influences and conditions which are peculiarly inimical to the young.

So much in passing; I must recur to this point. A paragraph in the first report does not lead to the same conclusion as another in the second. They are not irreconcilable. The former tends to show that there is no evidence that the non-domestic employment of mothers is injurious. The latter is to the effect that such employment "must necessarily" do harm. I agree with both of these apparently divergent conclusions. I have reason to know for my own district that the former is well founded (I went into the question in 1908), and I am convinced that the latter must be true. But to discuss the matter now would take too long. The influence of the industrial employment of women on family life generally, on child-bearing, and on the health and lives of the infants and children has not yet received adequate attention. It should be insisted upon that the family is the unit of the nation. The sum of the families is the nation. This social question of female industrial employment is so great and so complex that no individual can investigate it adequately, even in a lifetime, yet it needs investigation.

It may be worth while to express the opinion that the explanation of the apparent irreconcilability of these particular conclusions may be the following: Under satisfactory conditions of family life generally, if in a section of a community the mothers worked all day away from the homes we would be able to show statistically that such employment caused an excessive infant mortality. But the existing conditions are so bad, the infant mortality is so excessive, the margin between the inevitable minimum (of something less than 40 deaths per 1,000 births), and the mortality which actually prevails is so great that the effect of the mother's absence from her duties to her offspring is masked by the additional resources commanded by her wages.

I cannot readily accept the dictum that the experience of organizations which supply food to expectant mothers shows that the condition of the mother before parturition has a definite influence upon the capacity for suckling. On the face of it that conclusion appears to be unavoidable. How can an ill-nourished woman so develop during pregnancy that the mammary tissue shall become adequate? It is not to be expected. But we have yet to hear advanced the natural corollary that the uterine tissues of the under-nourished woman fail to increase and to function (except in such cases as come under the proper designation of asthenia). Moreover, we know that the trophic nerves are able to exercise a selective faculty. And also the oft-cited phenomena of the very low infant mortality observed during the Lancashire cotton famine and the siege of Paris increase the difficulty of acceptance of this opinion. True, other factors played a part in Lancashire and in Paris, but it is undoubtedly the case that infants were breast-fed by mothers who had undergone privation during pregnancy to an extreme degree, and who, moreover, were semi-starved during suckling. Nevertheless, all women generally, and all mothers in particular, hold the natural right at the hands of their fathers, husbands, and sons to be well nourished at all times. I merely deprecate this particular statement about nourishment and suckling lest it should form a reason, or an excuse, to withhold from the infant its natural and only proper food.

In concluding his first lecture, Dr. Moore dealt briefly with the painful and difficult phase of the infant mortality question which related to unwanted infants, and incidentally referred to what he, following many other writers,

¹ The lectures were published more at length in the *Lancet* for April 22nd and April 29th.

called the "mothering" of babies. "No doubt," he said, "robust infants can survive in its absence, but, on the other hand, it is well to recognize the fact that there is an inherent instinct and appetite in the young mammal to huddle and nestle against its mother's body, and to receive warmth and nourishment therefrom. This experience has led me to believe that in all cases these things are necessary for the well-being of infants, and that there may be certain cases where the lack of them determines the balance against the infant, even to the extent of causing its death."

Influence of Special Measures on Infant Mortality.

Dr. Moore began his second lecture by saying that while he substantially accepted the statements in the official publications of the Local Government Board, he was of opinion that in them too great importance was given to general sanitation as accounting for reduction in infant mortality observed during recent years, and too little to work specially directed to meet the particular circumstances of infant life. In Huddersfield the infant mortality-rate showed a distinct decline in and after 1907, when special work against infant mortality in that town came into full operation. After pointing out that it was well known that infant mortality was low in rural and generally in small urban districts, particularly in agricultural areas, he said that it was equally well known that the standard of sanitation in these very places was of the lowest, and continued as follows:

I by no means wish to suggest that general sanitation, and especially municipal cleanliness, do not favourably affect the health of infants as of inhabitants generally, but, speaking as one who has given close attention to the problem for a long while, I would lay stress upon the view that other factors are of a greater significance and importance. It is well known that a heavy toll on the lives of the very young is levied in industrial districts where the employment of women is at a minimum but where the standard of life is low as well as in other industrial districts where their employment is at a maximum. I believe that the explanation of the former phenomenon is that the infants are individually neglected in the homes of the people, and I have no doubt that a breast-fed baby living in insanitary surroundings but cared for by its mother would have a very much greater chance of surviving than one bottle-fed and neglected by its mother, however excellent might be the sanitation of the house and the district in which it lived. Instances have been adduced where in the same street in certain families there have been many surviving children, and in other families of a similar social grade the survivors have been few.

Relation of Infant Mortality to Rate in Next Four Years of Life.

In dealing with this subject Dr. Moore mentioned the statement that the result of preserving the lives of infants would have a generally bad effect on succeeding ages—a statement based on the argument that heredity rather than environment should be taken into account. The statistics of Huddersfield did not support such a contention:

The curve (he said) showing the death-rates per 1,000 per annum at ages from 1 to 5 years follows very closely the corresponding curve at age 0 to 1 year. But if the work against infant mortality were only temporary in its influence, the curve at succeeding ages ought to have shown a rise. Of course, this is not the case. I have referred to these arguments against the utility of endeavouring to reduce the infant mortality figure elsewhere and from another point of view. It really does not appear to be worth while to labour the point, but I will recall the fact that in the Local Government Board Reports on this subject the same demonstration is given, and over extended age-periods.

The result in Huddersfield was corroborated by a study of the death-rates at each of the first five years of life for England and Wales calculated per 1,000 survivors at each age-period. The curves, after making allowance for the greater vulnerability at the earliest age-period, substantially followed one another—that is to say, a reduction in the infant mortality-rate (deaths under 1 year of age) was followed by a reduction in the mortality in succeeding years.

The Principal Causes of Infant Mortality.

In Huddersfield during the period 1907–1914 there was a positive reduction of infant mortality. An analysis of the principal causes showed that during that period the proportion of deaths attributed to premature birth rose from 14.9 per cent. to 17.8 per cent.—a movement compatible with the belief that preventable deaths had been eliminated in part, thus increasing the proportion of deaths hitherto considered to be unavoidable. This belief was strengthened by the fact that of the other principal causes diarrhoea, bronchitis, convulsions, whooping-cough, and measles all showed a decline, and pneumonia only an increase. Under the head atrophy, debility and marasmus, there was also a very marked decrease—from 13 to 8 per cent. of the total deaths, a fact which militated against the common view that many deaths at early ages result from a lack of vitality consequent on premature birth.

The Relation between Birth-rate and Death-rate.

Both the birth-rate and the death-rate were declining in England and Wales. In the period 1871–1915 the reduction in the birth-rate amounted to 32.7 per cent., while that in the death-rate was 36.8 per cent.; but the birth-rate had fallen about 12 per 1,000 and the death-rate only 8 per 1,000. The fall was fairly uniform in both curves, but that of the birth-rate was the steeper, so that the two tended to run together, and it was necessary to keep in mind the fact that whereas there was nothing to prevent the continuance in the decline of the birth-rate, which might even be accelerated, human vitality fixed a point below which the death-rate could not fall.

Reduction of Infant Mortality in Large Towns.

From an examination of infant mortality figures in thirty of the large towns of England and Wales, and comparing the period from 1877 to 1906 with the period 1907 to 1914, he drew two conclusions—first, that the reduction of mortality and the saving of infant life had been very substantial; and, secondly, that it had not been gradual; improvement in sanitation, however, had been gradual. The same was true of municipal cleanliness, the spread of education, the habits of the people, and so on. The mean infant mortality figure prior to the special work against infant mortality in Huddersfield was 156; the mean since that work had been in operation was 105. The calculation of the complete expectation of life showed that this particular work had added three years of life to each generation.

Provision for Infant and Child Welfare.

Dr. Moore then passed in review the existing provisions for infant and child welfare, including the Children's Act and the Notification of Births Act. The notice to the sanitary authority of the existence of the infant was followed more or less completely and more or less systematically by a visit to the infant in its home. The quality of the services rendered was very unequal, and left much to be desired. From a scrutiny of the list of health societies issued by the National League for Physical Education and Improvement, it appeared that of the 489 different associations 9 were national, 70 were municipal—in the sense that they were associated with and assisted by different sanitary authorities, and the remainder purely voluntary. Dr. Moore estimated that the societies altogether assisted 155,000 infants annually. In six localities antenatal work of various kinds had been established; this side of the work was still very recent and undeveloped, and no doubt much more would be done in the near future. The movement for the establishment of milk dépôts seemed to have languished; 11 were opened between 1899 and 1906, 1 in 1910, and 1 in 1912. Four had been closed. The cost in relation to the number of infants helped appeared to be the stumbling block. There was no doubt that the cost per meal of pasteurized milk was considerable. On the other hand, it was imperative to provide food for infants which would not destroy them. The conditions of the industrial milk supply in this country were such that in hot weather the only milk commercially available for poor people did, in fact, destroy babies in large numbers.

British Medical Journal.

SATURDAY, MAY 6TH, 1916.

URGENT DEMAND FOR MEDICAL OFFICERS.

STATEMENT BY THE WAR OFFICE.

THE Central Medical War Committee has the authority of the Director-General Army Medical Service for stating that a considerable number of medical men is required at once for service in the Royal Army Medical Corps. The development of military operations has caused a large proportion of the medical officers who have hitherto been serving in this country to be detailed for service abroad, and it is essential that there should be others ready to meet future demands.

This request for officers has come before the enrolment scheme of the Central Medical War Committee has been completed. The Committee is therefore compelled to ask for volunteers from among both the enrolled and the unenrolled. Those willing to join within a month should send their names at once to the Central Medical War Committee, 429, Strand, W.C., or make direct application to the War Office.

ENROLMENT: AN EXPLANATION AND AN APPEAL.

SIR,—During the next few weeks the course of events seems certain to lead to renewed fighting, to very many casualties, and to a call for more and more doctors to tend the sick and wounded. The supply could be met—as, if other methods fail, doubtless it would be met—by conscripting medical men, but some time ago the War Office recognized that a certain scheme of voluntary enrolment could be made to give them what they wanted and in a better way. The working of the scheme, as is now well known, was entrusted in England and Wales to the Central Medical War Committee, a committee representing the profession at large and the several medical corporations and schools, and in close touch with the Insurance Commission, and the great Government departments which employ medical men.

This scheme of voluntary enrolment, as contrasted with conscription, appears to present certain very great advantages, in which both the community at large and the individual practitioner will have their share. In any circumstances some doctors must go and some be kept at home; but whereas with conscription the task of selection might fall into the hands of local lay tribunals, the voluntary scheme provides that in each district it falls to a local committee of medical men, whose professional knowledge and knowledge of local conditions enables them to form a better judgement both of the needs of the civil community and the difficulties of the individual practitioner; while in any case from their decision an appeal lies to the Central Committee.

This scheme of voluntary enrolment has been framed to secure also a due rotation of work and sacrifice; so that when the volunteer has completed the year of service for which he signs on he is free to return home, his place with the army being taken by

another—an arrangement fairer to himself and better for his civil patients than indiscriminate compulsion.

Now, the success of the scheme obviously depends on the number of enrolments. If the response is meagre, the Army Medical Department will be starved, or rather conscription must come. Moreover, the correlative provision for the civil population, and the fair distribution of sacrifice, will be imperilled. It is true that the response so far has been fair, but, with the spring campaign upon us, the need for more men, and yet more, is so pressing that there is considerable anxiety even in respect of the immediate future. The scheme can only work well if all, or practically all, our brethren of suitable age enrol themselves. However, we find that, not unnaturally, some are hesitating to enrol lest a lack of enrolments should expose them unfairly to be summoned. This cannot, in any case, happen, since the Committee has decided that no calls shall be made until 75 per cent. are enrolled. We are all proud of the record of our profession in the past, and of its splendid service in this war; we shall be still more proud if it rises to meet the crisis and will deal with it by voluntary effort. If by age and office we are sheltered from the claims of service, we know none the less clearly how hard is the call upon many of our younger brethren, with many of whom we have been in correspondence. Domestic duties or pecuniary claims may seem imperative; surely, however, when in the day of victory the old relations are restored, the public will know how to reward those of us who, setting all else aside, obeyed the call of King and country.

Let us conclude, as we began, by saying that the need is now so urgent, that the time for consideration cannot be prolonged. By the enrolment of all who are of military age the burden of each will be lightened.—We are, etc.,

Cambridge, May 1st.
Oxford, May 2nd.

CLIFFORD ALLBUTT,
WILLIAM OSLER.

All readers will recognize the grave importance of these two communications. The two documents should be read together. They are addressed particularly to medical men of military age, but they concern all members of the profession, for in order that a sufficient number of medical men of military age may be obtained it is necessary that others shall loyally help to do their work.

The statement of the Central Medical War Committee, made at the request of the Director-General A.M.S., has reference to the immediate situation. The military authorities require at once from England and Wales a considerable number of medical officers for the R.A.M.C. The need is urgent, as men who keep an open mind and think for themselves must have been quite prepared to learn, though probably we shall hear again about the medical men already in the service who are not being used as economically as possible. Allegations of this kind tend to unsettle men's minds and to give the weak-kneed excuse for hanging back, but the profession has by this time learnt how limited is the value to be put on this sort of criticism. In this particular instance the Central Medical War Committee satisfied itself by a personal interview with the Director-General at the end of last week that the demand now made for more medical officers is fully justified and cannot be postponed.

It is unfortunate that so large a demand should have come just at this moment, because enrolment is not completed. The Central Medical War Committee decided recently that no call on the enrolled should be

made unless and until 75 per cent. of the men of military age had signed the form of application for a commission. That percentage has not yet been enrolled. The demand of the War Office, however, is urgent. The only course the Committee can take in these circumstances is to make an appeal to the medical profession voluntarily to furnish the number required, in spite of the fact that enrolment is still incomplete. In taking this course the Committee is encouraged by the fact that many amongst the enrolled have already expressed their willingness to go so soon as they are told that they are wanted; in fact, but for the enrolment scheme some of them would ere this have sent in an application for a commission direct to the War Office. The Central Medical War Committee now invites these and others to send in their names at once, without waiting till the pledge given by the Committee as to the percentage of possible enrolments has been redeemed.

As things are with the country at this moment, medical men of military age, whether enrolled or unenrolled, are to understand that their services are now required by the army. The time is past when a man whose services can be spared is justified in refraining from taking a commission because in his own opinion he is better employed where he is. The extension of the fronts in various parts of the world and the military operations imminent will strain to the utmost the medical resources of the country, and a dearth of medical officers at this time cannot fail to have an effect in helping to prolong the war.

That the principle of the enrolment scheme cannot be applied fully at this moment is due to the unfortunate circumstance that a certain proportion of the men for whose advantage it was devised have hung back. This hesitation may, in part, have been due to a failure fully to understand the purpose of enrolment. It has been explained on many occasions, and it is stated once more with brevity and cogency in the letter from Sir Clifford Allbutt and Sir William Osler, who have always shown themselves as sympathetic towards private difficulties as jealous for the honour of the profession. They state very clearly the difference they perceive in the position of an enrolled man and of a man taken for service under any system of compulsion that may be introduced. The hints which the Central Medical War Committee has given in this direction on previous occasions have been in some quarters, we are informed, described as threats. They are not threats; they are statements of fact, as anybody who reads the daily newspapers and the reports of Parliament will conclude for himself. There are many differences between the man who voluntarily enrolls and the man who waits to be fetched. There are differences which affect the moral of the matter, but there is also this practical difference, that the medical man who takes service under the conditions which have been arranged in relation to enrolment has the advantage over other members of the community that he is only called upon to serve for one year. The stockbroker or lawyer who takes a commission in the army takes it for the duration of the war. So, too, the Territorial medical officer and the officers of the Special Reserve who were called up at the beginning of the war; they must serve for its duration. It is an absurd piece of petulance to read anything of the nature of a threat into the statement that the increasing difficulty in providing medical officers may lead to the abolition of the system of commissions for one year. It is a common-sense statement of a probability which every unprejudiced person can realize for himself.

Is it more consonant with the honour and interests of the profession to take service voluntarily or to wait to be dragged out by Act of Parliament? Is it more pleasant and decorous for a professional man to wait to be summoned before a local tribunal, there to have his duty and private affairs discussed by a body of laymen, or to accept the privilege of having his position fully considered by his peers? Can any medical man assert that the introduction of conscription will diminish, or indeed to any tangible extent affect, the difficulties which will have to be faced by a medical man called upon to enter the army?

We go back to the point that the army must have doctors. It wants a continuous flow into the Royal Army Medical Corps, and it wants an unusually large number at this moment. The relation of the medical profession to the civil population is a national question. It should be decided by a national body. A local tribunal is not competent to decide on the value of an individual medical man in relation to the values in other parts of the country.

It is true that compulsion now looms in the near future; but it is still essential that the medical profession should make the enrolment scheme a success. Let every medical man under 45 remember that the paramount interest of the country is that the war should finish as quickly as possible, and finish victoriously; that the medical service of the army is essential to its efficiency; that the service must have doctors in sufficient numbers; and that no man is really in a position to select himself, that is, to decide whether he should enter the medical service or stay at home. The Central Medical War Committee is the only body in England and Wales, and the Scottish Medical Service Emergency Committee the only body in Scotland, which has knowledge of all the difficulties and the methods of dealing with them. Fairness to all members of the profession as well as to the public requires that a proper selection should be made. We assert that these statements have never been seriously disputed; they are demonstrably true—in fact, axiomatic. The appeal is therefore to every medical man of suitable age who has not yet enrolled to do so. By enrolling he accepts the Central Medical War Committee or the Scottish Medical Service Emergency Committee as arbiter. He can enrol by filling in the form to be obtained from the secretaries of the Committee at 429, Strand, or the convenor of the Scottish Committee at the Royal College of Physicians in Edinburgh. He will thus be doing his share to ensure the success of a scheme which, while it will supply the needs of the army and preserve all that is essential for the treatment of the civil community, at the same time provides for the sympathetic consideration of the difficulties of individual medical men, and the maintenance of the dignity, honour, and interests of the profession as a whole.

LONDON SCHOOL OF TROPICAL MEDICINE.

SIR RICHARD HAVELOCK CHARLES, G.C.V.O., Serjeant-Surgeon to the King and President of the Medical Board of the India Office, has, at the request of the Secretary of State for India, accepted an invitation to become dean of the London School of Tropical Medicine in succession to the late Sir Francis Lovell. The institution is to be congratulated on having secured as its head a man whose professional and personal distinction will shed lustre on the office, while his administrative capacity and knowledge of the tropics will be of the greatest service to the school. Sir Havelock Charles has for a considerable time taken a deep interest in its fortunes. His long experience

in India, where he took a large part in the reform of the medical schools at Lahore and Calcutta and gained the confidence of native students in a very unusual degree, makes him peculiarly fitted for the post which he has now been called upon to fill. He may be trusted to co-operate in a spirit of friendly rivalry with Sir Leonard Rogers and his fellow-workers of the Calcutta School, the foundation stone of which was laid by Lord Carmichael on February 14th, 1914. An illustrated account of the institution as it will be when the buildings are completed was published in the *BRITISH MEDICAL JOURNAL* of March 7th, 1914 (p. 562). That school has a special function of its own to fulfil, and there is ample room for an Indian foundation as well as for Mr. Joseph Chamberlain's creation at the Victoria and Albert Docks. On the outbreak of the war the number of students at the London School dropped from sixty almost to vanishing point, and practically no post-graduate work is being done there. We are glad to learn, however, that the school opened its session on May 1st with ten students. Sir Havelock Charles comes to his new task at an anxious time, but we have the fullest confidence that his tact, energy, and wide experience in educational work will enable him to deal successfully with a difficult situation.

NEW MEDICAL BATHS AT TORQUAY.

A NEW chapter in the history of Torquay as a bathing station was begun on May 1st, when a large medical bathing establishment was opened on Beacon Hill, between the bay and the harbour. The baths are one result of an ambitious scheme of municipal development which has been going forward during recent years at this famous Devonshire resort. The idea of having an up-to-date system of medical baths was first started in 1910, and after a careful study of the bathing establishments at the inland spas, the work of converting the old bathing saloons to this new purpose was begun in July, 1914. Difficulties arising out of the war account for the fact that the work has only just been completed. The new baths consist of thirteen treatment rooms, with twice that number of dressing-rooms, and are divided into ladies' and gentlemen's suites. There has also been installed a large subterranean swimming bath. The decorative style of the whole work, in vitreous mosaic, is in harmony with the hygienic idea, and the outlook is open to the waters of the bay. The treatment given includes local vapour and electric baths, and baths of sea water and of medicated water, such as in the Nauheim, pine, and sulphur treatments. Provision is also made for Aix and Scotch douches, with water softened more than ordinarily; and a bath which it is hoped may become famous as a Torquay speciality is a salt and seaweed bath—or, as it is called on the east coast, an ozone bath—the seaweed at Torquay being prepared for application in a newer and rather better way than has hitherto been the case. On the occasion of the opening of the baths by the mayor (Mr. C. T. Towell), testimony was given by the Chairman of the Baths Committee to the assistance rendered by local medical men, some of whom had formed themselves into an advisory board in connexion with the work. With the completion of the task this advisory board ceases, but two or three medical men, including the President of the Torquay Medical Society and the Secretary of the South-Western Branch of the British Medical Association, have been appointed as a medium of communication between the Baths Committee and the local profession, so that this enlightened municipal enterprise will continue to be stimulated by an enlightened medical opinion. After the official opening, Dr. Fortescue Fox gave an address, congratulating Torquay on a climate favourable to the action of the baths, especially during the colder months of the year. The eastern part of our island, he said, was desirable for those who needed to be stimulated,

the western part for those who needed to be rested. The east quickened the pace, the west tranquillized and slowed down. He likened the Tor Bay portion of the Devonshire coast to the Italian Riviera, and expressed the opinion that Torquay as a marine climatic station promised many advantages for the after-treatment of disability arising from wounds. In this, as in general respects, more might be done in the way of associating British health resorts with one another, not in sterile rivalries, but in mutual co-operation. He had been struck by the strong individuality of our health stations. Each had its own characteristics, and in our little island there was room for all of them, especially now and in the immediate future. The co-operation of the local medical profession in this new Torquay venture was promised in the course of brief speeches by Dr. Winter (the deputy mayor) and Dr. Gervis. The company, which numbered a thousand or more, then made a detailed inspection of the bathing suites.

THE ROYAL ACADEMY.

THE one hundred and forty-eighth exhibition of the Royal Academy of Arts in London, now open at Burlington House, may be recognized at once as one of unusual merit. Seen in the turmoil of the Private View, when the floor is even more crowded than the walls, and the eye is continually distracted by meeting the originals of many of the portraits hovering in the immediate neighbourhood of their counterfeit presentments, this year's Academy gives an uncommon impression of strength and varied interests. The number of pictures of academic type and interest—we use the word "academic" in the Pickwickian sense—is not so large as usual. It would seem that the war has broadened the sympathies of both the contributors to the exhibition and the hanging committee alike. As is natural, there is a khaki tone about many of the most arresting pictures on the walls; here there is less of the flamboyancy noticeable in so many of last year's war pictures, and there is evidence of a better realization of the true horror of war. An excellent example of this will be found in Gallery No. VI, where "The Return to the Front," from Victoria Station, is depicted with a vigour and freedom from sentimentality that are rarely exhibited in compositions of this class. Zeppelin raids and aeroplanes in battle receive their due illustration, and the doings of our fleet are recorded in a number of fine canvases. Hospital pictures, too, are naturally to the fore, but surgeons will be horrified to see the pictures, which one must suppose to be accurate in detail, of the overfurnished and crowded rooms full of dust-collecting bric-a-brac that are now being employed as wards for the wounded. A khaki setting is the prominent feature of many of the portraits in the exhibition; portraits, usually the chief feature of the Academy, form this year a less important part of it, for one reason or another. There are, however, portraits of Royalty; there are many portraits of military men, young and old, and not a few of beauties, débutantes, and children. Why is it, one may ask, that children so often have to be painted with large, watery, and gleaming eyes that to the medical man are undoubted exemplars of "Bright's bright eye" and indicate nephritis? Probably the explanation lies in the words Corney Grain used to sing, "Which is very in-artistic, but the public like it best." Another feature of Academy exhibitions to which the public is inexorably attached is very fully represented this year; we refer to the problem pictures and morality pictures that hang on the walls in large numbers, awaiting solution or interpretation, and always attracting much interest and many spectators. There is even a medical problem picture in Gallery No. VII; standing in front of this canvas, many a medical man will be inclined to think that the doctor's prohibition here depicted has come a quarter or half a century too late.

WITTENBERG: A GERMAN DENIAL.

REFERENCE was made in the BRITISH MEDICAL JOURNAL of April 22nd to a semi-official denial by the German Government of the charges made against the administration of the Wittenberg prison camp in a report by the Government Committee "on the treatment by the enemy of British prisoners of war." Further denials, evidently inspired, have appeared in the German press. As usual, these are inconsistent. While in one quarter it is said that if in the early days some prisoners lacked clothes, this was due to their love of gambling, in another it is alleged that the "Wittenberg fables" are spread with the object of persuading the English soldiers, "whose courage needs various kinds of stimulants, that death is preferable to capture by the Germans"! Again, while it is asserted that energetic measures were taken as soon as the epidemic broke out, and medicines, wine, and milk were provided in large quantities for the prisoners, the excuse is put forward that at the beginning of the war the doctors did not possess the experience they have since gained. This is doubtless true, but it amounts to an admission that the outbreak was not, at any rate at first, dealt with effectually. The plea contrasts strangely, too, with Dr. Léonetti's story of a German doctor, who during the outbreak of typhus at Langensalza congratulated a French medical officer on having been brought to Germany, "where he would learn how to treat patients." It must also be pointed out that what the German papers call "the lying and slanderous report of the state of things at the Wittenberg camp" does not rest entirely on British testimony. In the *Times* of April 27th a French sergeant released in February was quoted as recording his "hellish experience" of Wittenberg. He speaks of it as a camp of misery where he had suffered tortures from hunger which brought on two heart attacks; where the prisoners' parcels were pilfered and their tins of preserved food prized open by German bayonets. He describes it as "the home of brutality, where police dogs were let loose unmuzzled among us in the barracks, where scourge and lash and knout were current change, and where the posts to which we were tied caused many an illness." He calls Wittenberg "a camp of death," where 800 of his comrades perished either from lack of care or from cowardly rifle fire. This exactly confirms the British report. Wittenberg is not the only German camp where sick prisoners were badly treated. Speaking of Cassel, private Archibald Allan, 2nd Battalion, K.O.S.B., says¹ that when he was transferred to an internment camp on the outskirts of the town there were fully 10,000 prisoners there, and typhus was raging. "It became so bad that the German orderlies were not allowed to enter the camp, and all the food for the prisoners was passed through wooden shoots" from the outside. "When the fever abated, the orderlies returned to their usual duties, but the sufferings of the prisoners did not diminish." We have more than once quoted the testimony of Dr. François Léonetti, and we may add that it is fully confirmed by Drs. Deléarde and Halluin, who worked at Langensalza and Niederzwehren during the outbreaks of typhus. Their report is published in the *Revue d'Hygiène* of April 20th. The story of these camps is a record not only of cruelty and cowardice, but of gross professional incompetence. The incapacity to put into practice the prophylactic measures which sanitary science, as it has been developed in more enlightened countries, has shown to be effective is one more striking piece of evidence showing the backwardness of Germany in this respect.

DENTAL RESEARCH AND DENTAL NURSING.

THE National Dental Association of the U.S.A. and others interested in philanthropic work have organized an institute the purpose of which, as more fully set out in the articles of incorporation, is to find and establish means for

the complete relief of mankind from the direct and indirect ravages of dental and oral diseases, to encourage research, and to acquire and administer property to carry out these objects. It is incorporated and has its offices in Cleveland, Ohio, and possesses two well-built houses containing twenty-five research rooms and a lecture room. Part of the work is to be carried on locally and part by means of grants in aid to workers in other parts of the U.S.A. A memorandum has been issued setting out a long list of subjects fit for investigation, ranging from systemic diseases resulting from oral infections to the finding of a substitute for platinum in dentistry ("one-third of the platinum used in the world is in the art of dentistry, amounting to about 2,500,000.00 dollars per year, and is lost"). Many of these subjects are already being investigated under the aegis of the institute. It has a limited membership of sixty. Of these, thirty-three are permanent non-dental members, elected from leading research scientists, philanthropists, and business men. Among them are such names as Victor C. Vaughan, Charles H. Mayo, George W. Crile, Frank Billings, and Mr. Thomas Forsyth. Such names are a guarantee of the earnest spirit in which the work is being entered on, and we congratulate the prime movers and organizers of the undertaking on the successful launching of their scheme. It will be no small benefit if by its means dental research in the U.S.A. becomes systematic and co-ordinate. While realization of its objects lies with the future, the known ability of those whose names are published as already at work under the guidance of the institute affords good ground for hope of ultimate triumph. Almost simultaneously with the announcement of the opening of this research institute we have news of the passage of a bill by the New York Legislature providing for the training, registration, and licensing of women to act as dental nurses. They may "graduate" as dental hygienists in one year. Their function is to scale and clean teeth, but they must always work under the supervision of a licensed dentist. Mr. Edward F. Brown, Secretary of the Dental Group of the Advisory Council of the Committee on Child Hygiene, New York City Health Department, explains that the object in view is the prevention of dental caries and oral sepsis, and credits Dr. Alfred C. Fones of Bridgeport with having already successfully experimented in the use of the "dental hygienist." It is intended that the dental nurse shall deal primarily with the teeth of the school population of New York City. The result of her work will be watched with interest. Her introduction may well be epoch-making in the history of public health.

TRAINING IN OPHTHALMOLOGY AND
OTO-LARYNGOLOGY.

Dr. Todd of Minneapolis has discussed recently, in *Ophthalmology*, the higher education of students desiring to become specialists in eye and ear surgery. He points out the necessity for a thorough course of instruction and training in both the theoretical and practical sides of these subjects. Post-graduate courses are useful to enable the general practitioner to rub up his knowledge of medicine and surgery, but attendance at a course of such lectures in a special subject does not make a man an expert, although in America it has led to the development of what Dr. Edward Jackson has called the "six-weeks specialist." Dr. Todd points out that a beginning has been made in England by the creation of the diploma in ophthalmology by the Universities of Oxford and Liverpool; this can only be regarded as a beginning, because neither is the reward of a thorough methodical training in the subject. Some of the American universities have gone further, and in 1914 the University of Minnesota Medical School established courses for the preparation of specialists, not only in ophthalmology, but in other branches of medicine. An

¹ *Glasgow Herald*, January 27th, 1916.

applicant must have graduated from a high-grade medical school, and must have acted for a year as house-surgeon at a general hospital. The courses cover a period of two or three years, and when completed the student, after he has carried out a piece of research, is granted the degree of D.Sc. in ophthalmology or other subject. Such a course of preparation might be organized in London in connexion with the special hospitals, and the degree of F.R.C.S. might be open to the specialist who has been so trained. It is an anachronism that the most coveted diploma in Britain should be the monopoly of the anatomist and general surgeon.

TRAUMATIC GLAUCOMA.

PROFESSOR GOLDZIEHER, of Budapest, has reported¹ two cases of glaucoma following injuries received in battle. He expresses the opinion that the question of primary glaucoma, consequent upon a concussion injury to the eye, has not received the attention it deserves, and recalls the views of von Graefe and Schmidt-Rimpler, who both denied the possibility of such an occurrence, and of Wagenmann, who allowed its possibility. In one of Goldzieher's cases the man, aged 29, was buried by explosion and was unconscious when dug out; on recovering consciousness both eyes were red and watery, but the left was more affected than the right. For a week after the injury he was also deaf; the right eye soon recovered, but at the end of a week he saw badly with the left. He quickly returned to duty and was transferred to the south-western front, where, in July, he was injured in the hand, and was sent to hospital. The right eye was then quite normal, the left almost blind from glaucoma; it was free from injection; the anterior chamber was deep and the iris normal; the pupil was moderately dilated and practically inactive to light. With the ophthalmoscope subcapsular opacity could be seen in the lens below the horizontal meridian; the capsule was uninjured; there was no subluxation or tremulousness of the lens; the vitreous was clear, and the disc deeply cupped. In the extreme upper periphery of the fundus was seen a bleached area with numerous fine dots of pigment regularly arranged, and some yellowish splashes of irregular contour with unpigmented edges. Goldzieher attributes the fundus change to retinal haemorrhage, and thinks that the lens opacity can be accounted for by the coup and the area of fundus change by the contrecoup. In the other case a Roumanian was injured by shrapnel in the left eye, which was free from injection but stone blind. From a small punctiform corneal opacity there extended backwards through the anterior chamber, which was of normal depth, a fine thread of anterior synechia connecting the corneal opacity with the anterior surface of the iris; the iris was otherwise normal, the lens and vitreous were transparent, and the disc deeply cupped. There can be little hesitation in pronouncing the second case to have been one of glaucoma secondary to the perforating injury with anterior synechia formation. It is well known in this country, and we should have expected also in Hungary, that glaucoma is by no means an infrequent complication of perforating wounds with anterior synechia formation. The fact is one of the strongest arguments in favour of dealing with all such anterior synechiae if possible by operation. This very complication not infrequently ensues in cases in which a broad synechia is present, though it is true glaucoma must be rare in connexion with so fine a tag of synechia as the author relates; in spite of this, we, however, see no reason to alter the view of the case expressed above. It is not so easy to account for the first case, though we are inclined to look upon this also as an example of glaucoma, possibly secondary to some low form of cyclitis following the injury.

¹ *Wien, klin. Woch.*, January 20th, 1916.

REPORTS ON THE CONDITION OF PATIENTS.

THE Central Ethical Committee of the British Medical Association had before it at its meeting on April 7th correspondence which raised the point whether a medical practitioner was justified in making a report upon the condition of a patient to a third party without the patient's knowledge and consent. The Ethical Committee adopted a resolution to the effect that medical practitioners should not furnish any such reports without the knowledge and consent of the patient. We are told that applications for reports are not infrequently made by lawyers to practitioners in attendance upon injured persons in connexion with proceedings under the Workmen's Compensation Act and otherwise, and that when met with a rebuff the lawyers are apt to reply that such reports are furnished in many hundreds of cases during a year. We are not prepared to accept a general statement of this kind as correctly expressing the practice of the profession. The ethical principle involved is simplicity itself. It is this, that the duty of a doctor called to attend upon a patient is to that patient and to nobody else. The only exceptions we know of to this rule are, first, if the patient be of tender age or *non compos mentis*, in which case the report must be made to the parents or guardians; and, secondly, certain specific instances in which the Legislature has thought fit to lay the obligation of giving a certificate upon a member of the profession, as in the case of notification of infectious disease.

THE next session of the General Medical Council will begin on Tuesday, May 23rd, at the Council's new premises, 44, Hallam Street, Portland Place, London, W. The President, Sir Donald MacAlister, K.C.B., will take the chair at 2 p.m.

Nature has received from Professor B. Menshutkin, of the Polytechnic Institute, Petrograd, the gratifying information that Professor I. P. Pavlov, the eminent physiologist, is alive and well. The report of his death, which reached this country last February, was due to a confusion of names. The professor who died was the distinguished surgeon, E. V. Pavlov.

THANKS to the courtesy of Sir G. H. Makins, treasurer, and Sir Wilmot Herringham, secretary, through whom thirty-one volumes have recently been received, the series of the volumes of the *Transactions* of the International Medical Congress in London in 1913 in the Library of the British Medical Association is now almost complete. The only volume now missing is Part I of Section XXII (Radiology), which is out of print. The Librarian will gratefully acknowledge the receipt of a copy of this part sent to him at 429, Strand.

Medical Notes in Parliament.

War.

Compulsory Military Service.—The Prime Minister began his statement to the House of Commons on May 2nd by dwelling on the actual growth which has taken place in the army since the beginning of the war. In August, 1914, the army at home consisted of 6 Regular and 14 Territorial divisions, in addition to the garrisons overseas, which might be roughly estimated at 6 divisions, making 26 in all. The country now had 42 Regular and 28 Territorial divisions, that is to say, 70, or, adding the Naval division, 71. In order to estimate the contribution of the empire as a whole, excluding India for the moment, there must be added 12 divisions from the Dominions, making 83 in all. The total naval and military effort of the empire from the beginning of the war to this time exceeded 5,000,000 men.

The obtaining of this enormous addition had involved a prodigious effort both here and throughout the empire. There were two limiting conditions in the matter of recruiting which applied to us, and hardly, if at all, to any of the other belligerent countries. The first was the maintenance of sea power and sea supremacy both by means of the navy and the mercantile marine, and, next, the financing of the Allies. Investigations made in July showed that to maintain a 70 division army a weekly influx of 25,000 to 30,000 men must be obtained. The provision of additional men, both those included in the bill introduced last week and the 200,000 still unattested married men, in the later part of the year, was of vital importance to the maintenance in due strength of the army in the field in view of the contingencies of the summer and autumn campaign. The Government's conclusion was that while the number of men required could not be obtained in due time under the existing machinery, the number needed was actually available, that was to say, could be spared from industry without incapacitating us from the discharge of our other responsibilities, which were quite as essential to the successful prosecution of the war as the maintenance of a fixed number of men at the front. Compulsion was a pure question of practical expediency, but if it was to be applied successfully it must be with something in the nature of general consent. In the bill to be introduced on May 3rd it was proposed to apply general and immediate compulsion, but it was not believed that a larger number of men would be got or in a shorter time; but general and immediate compulsion would have the immense advantage of getting rid of the piecemeal treatment to which so much objection had been taken in all quarters of the House, and of the sense of, at any rate temporary, injustice and inequality which that mode of treatment was apt to engender. Speeches made on April 27th from the Labour benches encouraged the belief that there was a general desire to settle the whole matter, with all the controversy and heated feeling which had been introduced, once and for all, and to get it finally out of the way at the earliest moment. Sir Edward Carson, who followed, took up Mr. Asquith's special reference to the Labour party. No distinction, he said, ought to be drawn between classes. Every class had given of its best to the war, and while feeling full sympathy with anybody who had to give up his house and home to fight for his country, he believed that the classes which would suffer most were the professional classes, many of whom had sent him bitter tales of what had happened to their business and to their families, and of the bringing up of their children in the sphere of life in which they were born. But there was no difference in classes: it was equally hard upon everybody. The ensuing discussion lasted about three hours, but did not elicit any points of novelty. The Prime Minister, in introducing the bill on May 3rd, said that the first clause subjected all males between the ages of 18 and 41, married or single, to compulsory enlistment in the army, every male coming within the operation of the bill as he reached the age of 18. It would come into effect thirty days after it was passed, or thirty days after a lad attained the age of 18 subsequently to the passing of the bill, but he could voluntarily enlist during this period of grace. These provisions were subject to the exceptions contained in the first schedule of the Military Service Act. The second and third clauses provided for the extension during the period of the war of the services of men now serving, and for the recall to the colours of time-expired men, whether married or single, if at the time of the passing of the bill they were under 41 years of age. The bill also empowered the Army Council to review the medical certificates of those rejected on medical grounds since August 14th, 1915. The reason for this, Mr. Asquith said, was that the standard of medical fitness had now been extended, and men not fitted for service abroad were being taken for less arduous duties. It was desirable that there should be an opportunity to review them, and he believed a great many of the men would be glad to be reviewed. The fifth clause dealt with the exemption for two months given under the Military Service Act to a man leaving industries of national importance with the intention of joining others of like character. The bill would also provide for the formation of a special reserve to which men in the army or Territorial

Forces might be transferred, the intention being that men in this reserve might be or would be employed to a large extent in civil life, but would be immediately available for military service in case of military necessity. The bill also authorized the transfer of Territorials into other corps of Territorials or regular battalions. After a short discussion, Mr. Long replied, and the motion to introduce the bill was carried.

Prisoners' Camps, Germany.—In reply to Mr. Malcolm, on May 2nd, Sir Edward Grey said that it appeared from notes received from the United States Ambassador at Berlin in April and May, 1915, that typhus was present at Zossen, Altdamm, Schneidemühl, Gardelegen, Wittenberg, Zerbst, Sagan, Cassel, Erfurt, Langensalza, Ohrdruf, Chemnitz, Altengrabow, and Salzwedel. Unofficial reports had reached His Majesty's Government that, in addition to Wittenberg, Altengrabow and Schneidemühl were abandoned by the Germans. As regarded Gardelegen, it appeared that, except for one German doctor who died at his post and another who acted in a most praiseworthy manner, the camp was deserted by the Germans. The fact that typhus was present at a camp prevented officials of the United States Embassy at Berlin from furnishing officials' reports based on personal inspection. All the reports received from the United States Embassy down to March 31st would be included in a forthcoming White Paper.

Invalid Prisoners and Swiss Resorts.—Further questions were asked on this subject in the House of Commons on May 2nd, but as the Press Bureau issued a communication on the evening of the same day, it will be more convenient to reproduce it.

The Secretary of State for Foreign Affairs learns from the United States Ambassador that the German Government have accepted the proposal of His Majesty's Government for the transfer to Switzerland of British and German wounded and invalid combatant prisoners of war. The precedent formed by the arrangement between France and Germany will be followed as closely as possible.

The Swiss Government have been requested by telegraph to send the necessary number of doctors to examine the German prisoners in this country. A party of Swiss doctors is already in Germany for the purpose of examining the French prisoners, and advantage will no doubt be taken of their presence to examine the British prisoners.

Officers' Ration Allowance.—In reply to Colonel Yate, on April 27th, the Financial Secretary to the War Office said that the ration allowance to officers of the Territorial Force, applicable in cases in which officers were able to draw rations in kind, but preferred for their own convenience to draw the cost in cash, was 1s. 3d., which was the actual cost of the present ration.

Reduction of Notification Fees.—The Lords' amendments to the Local Government (Emergency Provisions) Bill were considered by the House of Commons on May 2nd, and a drafting amendment in the clause reducing the fee for notification from 2s. 6d. to 1s. was agreed to.

Motor Car Duties.—The Chancellor of the Exchequer said, on April 27th, that it was not proposed to interfere with the existing exemptions in respect of motor car duties. Trade cars, fire-engines, motor cars used by a local authority for fire brigade purposes, ambulances, and cars brought into the United Kingdom by a person making only a temporary stay were totally exempt. Motor vehicles kept by a duly qualified medical practitioner for the purposes of his profession were chargeable with one half of the duty. The question whether it would be possible to extend exemption to cars used exclusively for public purposes was under consideration. In a written reply to Mr. Byrne, who asked a question as to the injustice of the proposed new taxes to Irish motor users whose cars were, with few exceptions, either of old pattern or of American makes, Mr. McKenna said that the whole question of the proposed increase in the motor car licence duty was receiving careful attention, but he was not prepared to adopt the suggestion that the value of cars should be the basis of the tax.

The report of the Committee of Visitors for the year 1915, presented to the annual meeting of the Royal Institution on May 1st, testified to continued prosperity and efficient management. Sixty-two lectures and nineteen evening discourses were delivered during the year, and 803 volumes, including bound volumes of periodicals, were added to the library.

THE WAR.

BRITISH RED CROSS CONVOYS AT VERDUN.

(From a Correspondent in Northern France.)

THE nature of the assistance that the British Red Cross Society has been affording in the Verdun fight can be described in half a dozen words—it is fighting line evacuation work. But the relations between the society and the French authorities require rather more explanation. They commenced, not at Verdun, but quite early in the war, varied in their character for a good many months, and crystallized to some extent about the time of the extensive operations in Champagne, and recently assumed a definite and probably final form, and this is practically as follows:

(1) The society undertakes to supply, and the French authorities agree to accept, the assistance of a certain number of convoy sections. (2) As soon as any such section reports itself for duty it becomes for the time being an intrinsic part of the French army, the cars being regarded as part of the French mechanical transport equipment and the personnel as French soldiers. (3) As such the drivers and section leaders are billeted and rationed, receive the ordinary pay of French troops engaged in the same work, and belong to the Service de Santé command.

This does not mean that when the society has delivered at a given spot a certain number of ambulances and a certain number of trained men it ceases to have any connexion with the matter. Its ownership of the cars is not altered by the fact that they are under the absolute control of the French authorities, and its responsibilities towards the workers continue, even though these rank for disciplinary and all other purposes as French soldiers.

In other words, the cars, or what is left of them, return into its possession when no longer required by the French, and meantime it is responsible for the maintenance of a personnel to work them, and for the salaries that it has previously agreed to pay the men who constitute it.

The arrangement sounds curious, perhaps, but really there are plenty analogies for it in civil life. Something of the kind was necessary, because in such a vast business as the conduct of a war it is inconvenient to depend upon labour which is not under absolute control.

In the early stages of the war the French authorities accepted the assistance of many private individuals who were in a position to assist in the removal of the wounded from the battle line to the hospital areas. The disadvantage of this kind of assistance soon became obvious, and little by little the French began to exclude volunteer ambulance workers from the war zone, unless they agreed to cease to operate as independent workers, and to become units in a definite organization.

They also applied the same principle in dealing with members of the British Red Cross Society. Many individuals more or less closely connected with the society began to do ambulance work for the French in the autumn of 1914, a considerable number of them being citizens of the United States of America, who brought over their own cars. Eventually they were organized by the British Red Cross Society into two small ambulance units, and both of them did a great deal of useful work during the first half of 1915. But in the summer of that year the British Red Cross Society allowed one of them to break up; many of its cars were no longer roadworthy, and the officer who had been in charge of it had been offered other employment. The other convoy, however, the society decided should still be maintained, but that after it had been refurbished it should be handed over entirely to the French.

In the early autumn of last year, when the Artois-Champagne operations were in progress, this unit found itself overworked and the officer in charge of it asked the British Red Cross Society for the unofficial loan of another dozen ambulances. These were supplied forthwith by the British Commissioner in France, and the augmented unit did such valuable work that the question was raised whether the loan should not become permanent, and other units be allotted to the French on the same lines.

At first the answer seemed likely to be in the negative for the central authorities of the society in London were not disposed to approve the scheme on account of the expense involved. Fortunately, however, just at this moment a cheque for a very large sum was placed at the disposal of the Commissioner in France by a former ambulance worker in France, who on his return home had devoted himself to collecting subscriptions for ambulances. It was then at once arranged to put the idea into operation forthwith, and eventually to supply the French with three sections or ambulance units in all.

The first of these sections was ready just before the battle of Verdun began, and two other sections have since been sent down. There are therefore now some sixty-six British Red Cross cars at disposal in the Verdun area. They work in three main divisions, each of which is in effect a complete unit, since each has its own repair lorry, a travelling kitchen, and a touring car for the use of the section leader, who is responsible for the work and discipline of his section and any subsections, that it may form. In addition there is an officer who exercises general supervision over the whole convoy, and ranks as the local representative of the British Red Cross Society.

Judging from the reports that have filtered through, the conditions of life in which this Verdun convoy is doing its work are rougher than those to which motor ambulance convoys are subjected on the Flanders front, and the work itself in some respects more trying. Apart from going on night after night, the distances that some sections and subsections have to travel before they can unload seem to be very great, and there is a paucity of roads fit for heavy motor traffic. Some subsections seem also to be doing work which on the British side is not allotted to convoys but to field ambulances—that is to say, they are collecting from first posts within easy reach of machine gun and rifle fire.

All, too, seem to have to pass frequently along roads lying between the heavy artillery positions on both sides. Shells can consequently be heard whistling overhead, and though they may constitute no particular danger, the possibility of some of them falling short always exists. The noise, too, is great, for the line is more or less curved, and consequently guns seem to be banging from every direction.

It is clear, therefore, that the men attached to the convoy are justifying their existence to the full, and that the British Red Cross Society is well earning any credit which it may receive in respect of this matter.

BRIGHTON HOSPITAL FOR PATIENTS WHO HAVE LOST LIMBS.

THE Pavilion Military Hospital, Brighton, until lately used for the treatment of sick and wounded Indian troops, has been thoroughly renovated, and is now open for the reception of English wounded. A special feature of this hospital is that two divisions, comprising over 500 beds, have been entirely renewed for the treatment of patients who have lost one or more limbs. It has been found that many patients who have undergone amputation have had a long and tedious convalescence, which might in many cases have been considerably shortened if the best means of treatment of their stumps had been available; they would include those cases which, owing to necrosis of bone with discharging sinuses, have been sent from hospitals to convalescent homes to make room for other wounded.

The conditions for which it is especially intended that patients shall be admitted to the Brighton hospital are (1) persistent sinuses after amputation; (2) bulbous nerve ends in stumps; (3) adhesions limiting the free movements of a joint; (4) flexion of joints by contraction of scar tissue; (5) cases requiring re-amputation, as, for example, for conical stumps, and after flush amputations which have not properly healed. Shortly, any condition of stump which does not allow the proper fitting of an artificial limb will be considered suitable for admission. When a patient has been successfully treated for any of these disorders, and his stump is quite ready for fitting an artificial limb, he will be transferred to Queen Mary's Auxiliary Hospital, Roehampton, to have this artificial limb supplied.

It is hoped that workshops may be opened at the hospital

at which men will be taught trades during their stay. These trades will, of course, vary with the condition of the men, and care will be taken that the particular trade selected shall be suitable to the particular deformity.

The hospital is under the command of Colonel Neil Campbell, C.B., C.I.E., who was in command of the hospital for wounded Indian soldiers in the same building. The officers in charge of the two divisions are Lieutenant-Colonel Davis, I.M.S., and Major Brailey, R.A.M.C. The wards are of good size, airy, and well arranged, the largest containing about 130 beds. There are two operating theatres, an x-ray room, a disinfectant, cook houses, a canteen, and all that is necessary to make a military hospital complete in all details.

TRAINING SCHOOLS FOR MAIMED SOLDIERS.

ONE of the most urgent problems created by the war is the provision of new means of livelihood for soldiers incapacitated by wounds from carrying on their previous occupations. For this purpose arrangements have been made in most of the belligerent countries for the establishment of schools in which men crippled, blinded, or otherwise disabled can be trained for such work as their condition allows them to do. In this country the Incorporated Soldiers' and Sailors' Help Society, besides supplying financial help until the formalities required for the granting of pensions are complete, instructs men in useful trades, and when they have acquired sufficient skill employs them in its own workshops. Men with one arm are taught painting and other trades in which two hands are not needed, or they are engaged in feeding wood or paper to hand machinery. A year ago the society had workshops in London, Edinburgh, Dublin, and Brookwood (Surrey), and was taking steps for a large extension of its operations. Mr. C. Arthur Pearson's work at St. Dunstan's, Regent's Park, in the treatment and training of blinded soldiers and sailors is known to every one. In the *BRITISH MEDICAL JOURNAL* of November 20th, 1915, it was announced that at the suggestion of the Scottish Veterans' Garden City Association, the president of which is Lord Wemyss, a scheme had been worked out for the establishment in the various areas of Scotland of villages where the maimed soldier might find a home for his family and be trained in some useful work by which he might supplement his pension. Ground has been secured at Longniddry, not far from Edinburgh, and an interesting account of the work with plans and other illustrations has been issued by the association. In Ireland a hospital, designed for 4,000 wounded Irish soldiers, has been established in Tipperary; those unable to resume their occupations are given instruction in wood and metal working, typewriting, and telegraphy. In France the Ministries of War and of the Interior have been studying the whole question. But official action is slow, and in the meantime a movement started by Maurice Barrès, the distinguished writer; M. Edouard Herriot, Senator for the Rhône department and Mayor of Lyons, and Dr. M. Carle, has led to the establishment of schools for maimed soldiers at Lyons, Saint-Maurice (near Paris), Marseilles, Bourges, Montpellier, Saint-Etienne, Bordeaux, Toulouse, Pau, Orleans, Nancy, Rouen, Havre, Clermont-Ferrand, Tourvielle, and several other towns. Dr. Carle, who is physician in chief to the schools, in his book *Les Ecoles professionnelles des blessés*, which was reviewed in the *JOURNAL* of December 11th, 1915 (p. 862), gives the fullest account we have seen of the objects aimed at, and the methods adopted for their attainment. The training is either commercial or industrial. In the former class maimed men who have completely recovered, and who are free from tuberculosis, are taught what might be called clerking in all its branches; the course comprises French, writing, shorthand, book-keeping, commercial geography, with English and Russian as optional subjects. The industrial classes comprise bookbinding, shoe-making, tailoring, carpentering and toy making, iron and wood work, basket and broom making, modelling in clay, harness making and general saddlery. Workshops for the manufacture of orthopaedic apparatus are being organized. The school at Tourvielle has a section of horticulture, where all the sheds and conservatories have been built by the pupils. The men receive, in addition to their pension

of Fr.1.70 a day from the State, an allowance of Fr.1.25 a day from the school, together with the proceeds of their labour, whether done for the institution or in fulfilment of orders from outside. In Germany an institution for the supply of artificial limbs has been established at Charlottenburg; there the sort of work which the wounded men are fit to do is decided upon, and they are trained as workers in metal and wood, transport labourers, textile workers and agriculturists, and taught to work with the hoe or broom, and to drive carts. The German National Education Society has raised a fund of £25,000 to assist the blind until the State gives them suitable employment. They are trained as telephone operators, typists, and masseurs; those who are musically inclined are given instruction in music. The Hamburg Society for the Blind assists blinded soldiers till they can return home and take up the work of learning some trade. The Austrian Red Cross has established schools for crippled men; in the early part of last year four institutions for the teaching of trades were at work in Vienna and one in Prague. In Italy committees have been formed at Milan, Bologna, Florence, Turin, Lucca, Leghorn and elsewhere for the training of mutilated soldiers in new occupations. In an address on the re-education of the wounded, delivered in Rome not long ago, Professor Foà said that after four months of war Italy had 1,160 maimed men; statistics extending to November 20th, 1915, brought the number up to 4,000. To these must be added many cases of men disabled by frostbite. In New York a Permanent Blinded Relief Fund for Soldiers and Sailors—British, French, and Belgian—has recently been organized. It is estimated that six months' training will enable blinded men to earn their living. The idea of training schools for wounded soldiers is not new, though it has never before been acted upon on so large a scale as the exigencies of the present war have made necessary. It is not only a matter of livelihood for the men, but of peace of mind and freedom from anxiety and depression. The whole question is ably dealt with by Dr. Borne in a book, entitled, *La rééducation des blessés et des mutilés de la guerre* (Paris: Renouard, 1915), which may be studied with profit by all who wish to take an active part in soothing the lot of our maimed heroes.

THE ST. JOHN HOSPITAL, SOUTHPORT.

In the *BRITISH MEDICAL JOURNAL* of April 22nd (p. 603) reference was made to the work of the St. John Hospital, Southport, which is the largest V.A.D. establishment in England. The medical officer in charge, Mr. W. C. Bental, F.R.C.S., has sent us an interesting account of the hospital; we regret that, owing to want of space, we can only publish a brief summary of his article. In the early days of the war one of the ordinary V.A.D. hospitals was started with thirty beds. The institution received such enthusiastic support from the citizens of Southport under the active leadership of the mayor, Alderman J. E. Willett, that it was decided to provide for a large expansion of the original scheme. The loan of two mansions, each with extensive grounds attached, was obtained, and on these grounds a hospital was erected on the pattern of the 1st Eastern General Hospital at Cambridge. Southport was then able to offer to the War Office a hospital of 500 beds with staff complete. It is within the area of the Western Command, which has its head quarters at Chester. Though graded as a "Primary" hospital, in order to save extra official work, it is linked to the 1st Western General Hospital, Fazakerley, Liverpool. It consists of eight blocks, connected by covered ways. Each block consists of a ward with sixty beds opening on the common corridor at one end, where are a nurses' room and the ward kitchen. Across the corridor are three rooms connected with a sanitary block containing a lavatory and a bathroom for the men, and a nurses' sanitary room for the storage of bed-pans, with cleansing appliances. The wards are open to within two feet of the floor on the south-west side, and, as a protection against wind and rain, there are alternate windows and shutters on lift-off hinges; to ensure a sufficient supply of fresh air when these have to be closed, a 9-in. opening under the eaves runs along both sides of the ward, while in the gable at each end there is another opening for ventilation. Besides the kitchen and food storage department, which is quite separate from the other buildings, the hospital contains a

dispensary, nurses' dining-room, cloakroom accommodation, linen stores and sewing-rooms, together with matron's and kitchen superintendent's offices. In the reception block there is a large, well-heated waiting-room which opens into an undressing-room, off which is a small store for dirty and infected clothes. The men on arrival are stripped and bathed; then they go into the dressing-room where hospital clothes are supplied, and from this they go to the wards. After thorough stoving kits are placed in a pack store. In each branch of the hospital there is a spacious and fully equipped operating theatre. Trains bring wounded direct from Southampton. In addition to the men from abroad there is a steady stream of cases—hernia, appendicitis, varicocele, etc.—from the troops billeted in the town. One of the hospitals has been practically rearranged as a hospital for dysentery and enteric fever, with an extensive department for bacteriological examinations under the supervision of the honorary pathologist, Dr. E. Cronin Lowe. In the x-ray department, under the supervision of Mr. Thurstan Holland and Dr. Oram of Liverpool, there is a full plant for electrical treatment, massage, diathermy, etc. One-third of the practitioners in Southport have joined the forces, and the medical staff of the hospital consists of twenty-two temporary divisional surgeons (who are not-commissioned or paid) appointed by the Order of St. John from the practitioners remaining. These surgeons constitute a medical board which meets monthly. The management of the hospital is in the hands of a council representative of all interests concerned, with a chairman under whose cognizance all matters of expenditure and administration are brought. In the administration three Voluntary Aid Brigade Divisions of the St. John Ambulance Association, one of men and two of women, work together.

There is a matron at each hospital, with a staff of thirty-four trained nurses, who take charge of the wards, and are assisted by a staff of V.A.D.'s. The total cost of the buildings with full equipment amounted to £12,000, which was raised by public subscription. For maintenance the War Office makes a grant per day for every wounded man, and the people of the town are liberal in their support of the hospital, of which they are very proud. A permanent record of the work of the St. John Hospital, Southport, has been issued by the medical officer in charge, in the shape of a book, containing, in addition to a short history of its development, descriptions of its various departments and other appropriate literary matter. The work is illustrated by a number of admirable photographs. The whole forms a pretty souvenir of an effort for the relief of our sick and wounded warriors which is in the highest degree creditable to the people of Southport and to the medical profession of the town.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died on Service.

The battleship H.M.S. *Russell* struck a mine in the Mediterranean on April 27th, and sank, with considerable loss of life. Of the officers, twenty-seven were killed or died of their injuries. Among the latter were two medical officers—Fleet Surgeon W. R. Center and Surgeon P. D. Pickles, R.N.V.R., who died in hospital at Malta on April 28th.

Fleet Surgeon William Rudolf Center was the son of the late Brigade Surgeon W. Center, I.M.S. He was educated at University College, London, and at the Universities of Aberdeen, Edinburgh, Strassburg, and Berlin. He took the M.B. and C.M. with honours at Edinburgh in 1893, and the M.R.C.S. and L.R.C.P.Lond. in 1896. Entering the navy in 1896, he became Fleet Surgeon on May 13th, 1912. He qualified as an interpreter in German in 1911.

Surgeon Philip Dobson Pickles, Royal Naval Volunteer Reserve, who died in the Malta Naval Hospital from the effects of the fumes following the mining of H.M.S. *Russell*, was the son of Mr. J. J. Pickles, surgeon, of Leeds, and was 33 years of age. He was educated at Leeds Grammar School and Leeds University, and took the diploma of L.M.S.S.A. in 1908, subsequently holding the posts of resident medical officer, Leeds Public Dispensary, house-physician of Leeds General Infirmary, and clinical assistant at Armley Hospital, Leeds Tuberculosis Association, after which he went into practice at Earby, near Skipton

in Craven. He joined the R.N.V.R. on March 16th, 1914, and on the outbreak of the war was appointed to H.M.S. *Russell*.

ARMY.

Died of Wounds.

Lance-Corporal Robert Gordon Caldwell Stewart, M.D., of the 15th Royal Highlanders, C.E.F., died on March 29th, at the Toronto General Hospital, from the effects of a wound received at the battle of St. Julien in April, 1915. Dr. Stewart, who was a graduate from the medical college of Dalhousie University, was in practice at Kingston, Ontario, when the war broke out, and held the military rank of sergeant-major in the 48th Regiment of Toronto. He at once gave up both professional and military rank and enlisted as a private in the 15th Royal Highlanders, and was soon promoted to be lance-corporal. At the battle of St. Julien, as he was attending to a wounded comrade, a rifle bullet penetrated the back of his head, emerging at the corner of his left eye. For some weeks he was deaf, dumb, and blind, but gradually the effects of shock disappeared, and he recovered speech and hearing, and finally the sight of his left eye. He returned to Canada, and was operated upon in the hope that the sight of the other eye might be restored, his only desire being to return to the front. Unfortunately his death occurred two days later.

Died on Service.

Major Paul A. Gillespie, M.D., of the South African Expeditionary Force, German West Africa, died of bubonic plague on March 24th at Winburg, South Africa. Major Gillespie, who was in his forty-ninth year, was born at Cannington, Ontario, and was educated at the Jarvis Collegiate Institute, Toronto. He entered the University of Toronto and received his medical degree in 1890. He practised for six years at Penetang, Ontario, and then went to South Africa and commenced to practise at Winburg. When war broke out he became a medical officer in the force commanded by General Botha, and again offered his services for the German East African campaign under General Smuts with the rank of major. On one occasion Major Gillespie was taken prisoner and condemned to be shot as a British spy; fortunately, however, the British forces captured the town in which he was prisoner before the sentence was carried out.

Captain Edward Wilkinson Deane, whose death was announced in the casualty list published on May 1st, was born in 1872, joined the Australian Army Medical Corps last year, attaining the rank of captain in May, 1915, and came over to Europe with the first reinforcements from Australia.

Captain Edward Bush Hartnell, R.A.M.C.(T.F.), was announced as having died on service, in the casualty list of May 2nd. He was educated at Bristol, Dublin, and Guy's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1892. After filling the posts of junior house-surgeon of Chesterfield Hospital and resident medical officer of Dover Hospital, he went into practice at Bridgewater, in Somerset. He joined the 14th London Mounted Brigade Field Ambulance as lieutenant on September 22nd, 1914.

The casualty list published on April 28th includes the name of Captain R. R. J. Holmes, R.A.M.C.(T.F.), as having died recently on service. He died of fever, contracted on service, in the military hospital, Malta. He was the only child of the late Captain Robert Holmes of Cloncaugh, Woodlawn, co. Galway. He joined the 1st (Maidstone) Home Counties Field Ambulance as lieutenant on August 22nd, 1914, and became captain on April 1st, 1915.

The death of Lieutenant Guy Verney Fletcher, R.A.M.C., was also announced in the casualty list of May 1st. He was educated at Melbourne University, and took the Scottish triple qualification in 1899, also the M.R.C.P. Edin. in 1901. He subsequently served as second resident physician of Monsall Hospital, junior resident surgeon at the Royal Eye Hospital, Manchester, and assistant medical officer of Brownlow Hill Infirmary, Liverpool. He took a temporary commission in the army in May, 1915.

Lieutenant A. L. Thornley, R.A.M.C., who died after a protracted illness, was the son of Dr. and Mrs. Thornley of Bolton. He received his early education at the Bolton High School for Boys, and Epworth College, Rhyll. He

studied medicine in Edinburgh University, where he graduated M.B., Ch.B. Edin. in 1907. After this he went to Berlin to study ear, nose, and throat work, and from there was appointed house-surgeon to the Birmingham Ear, Nose, and Throat Hospital. He afterwards went to the King Edward VII Hospital, Cardiff, and acted as house-surgeon to the ear, nose, and throat department for two years, and for six months as house-surgeon in the surgical wards. He commenced practice in Cardiff as an ear, nose, and throat specialist, and was appointed by the corporation to attend ear, nose, and throat cases notified for treatment by the school medical officer. He was secretary of the Cardiff Division of the British Medical Association, which post he had to relinquish on accepting a commission in the R.A.M.C. He had been instrumental in getting a large number of medical men to accept commissions in the army.

Accidentally Killed.

Captain Reginald Kinloch MacGregor, R.A.M.C., was notified as accidentally killed, in the casualty list published on May 2nd. He was educated at St. Bart's, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1911. Entering the R.A.M.C. on August 7th, 1914, as a temporary lieutenant, he was promoted to captain on completion of one year's service.

Wounded.

Major C. A. J. A. Balck, R.A.M.C. (Dublin).

Major Walter Bapty, M.D., 2nd Canadian Mounted Rifles.

Captain W. McK. H. McCullagh, R.A.M.C., Special Reserve (Dublin).

Lieutenant C. Heald, R.A.M.C., temporary (aeroplane accident).

Lieutenant T. D. Miller, R.A.M.C., temporary.

Missing.

Lieutenant and Quartermaster E. H. Atkins, R.A.M.C. (Dublin).

Captain J. H. Beilby, R.A.M.C. (T.F.), Worcester Yeomanry.

DEATHS AMONG SONS OF MEDICAL MEN.

Johnston, Alec Leith, Lieutenant King's Shropshire Light Infantry, son of Dr. George Johnston, of 23, Seymour Street, London, W., killed in action on April 22nd. He was educated at St. Paul's School and at Exeter College, Oxford, holding scholarships at both; and was the writer of the series of articles "At the Front" and "At the back of the Front" in *Punch*. He got a commission as second lieutenant in February, 1915, and became lieutenant in August.

Marsh, T. E. L., Acting Lieutenant Royal Marines, second son of Fleet Surgeon Marsh, R.N. (retired), of Liss, Hants, lost in H.M.S. *Russell* on April 27th, aged 19. He was educated at Malvern College, passed into the Royal Marines just before the war, and joined the *Russell* in April, 1915.

Webb, George Tudor, Second Lieutenant Royal Fusiliers, youngest son of the late Dr. W. H. Webb, of Kingsbridge, killed in action on April 21st, aged 26. He got his commission last July.

MEDICAL STUDENTS.

Binning, William B., Machine Gun Corps, died of wounds, aged 19. He was educated at Failford School, Cowdenbeath, and at Beith Higher Grade School, and was studying medicine at Edinburgh before the war. He got a commission as second lieutenant in the 11th (Service) Battalion of the Cameronians (Scottish Rifles) on December 14th, 1914, and went to the front in October, 1915.

Edwards, A. J. A., Second Lieutenant Royal Scots, attached Loyal North Lancashire Regiment, died of wounds, was a native of Durban, South Africa, and a medical student at Edinburgh. He joined the 11th Service Battalion, Royal Scots, as second lieutenant on February 4th, 1915.

Tresidder, Charles Tolmie, Captain Gloucester Regiment, who was mortally wounded on the night of April 17th-18th, was the youngest son of Captain T. J. Tresidder, C.M.G., late R.E. After being educated at Uppingham and Dulwich College he studied for the medical profession at St. Bartholomew's Hospital, and would have taken his final examination before the war but for the accident of breaking his leg when playing football. He served for three months as a dresser with the Duchess of Westminster's War Hospital. He received a commission in the Lancashire Fusiliers on January 9th, 1915. He was promoted lieutenant on May 4th, and, having taken a first class instructor's certificate with distinction in machine gun work, was shortly afterwards gazetted captain. He subsequently transferred to the Gloucester Regiment, and was given the post of brigade machine-gun officer.

HONOURS.

A SUPPLEMENT to the *London Gazette* of May 2nd, issued on May 2nd, announced the following promotions and appointments to members of the medical profession for distinguished service in the field:

C.B.

Temporary Colonels:

C. A. Ballance, M.V.O.
F. D. Bird, M.D., F.R.C.S.
Sir Victor A. H. Horsley, F.R.S.
William Hunter, M.D., F.R.C.P.
V. Warren Low, M.D., F.R.C.S.
A. W. Mayo Robson, C.V.O.
C. Snodgrass Ryan, M.B. (Colonel Australian A.M.C.).
J. Purves Stewart, M.D., F.R.C.P.
Charters J. Symonds, M.D., F.R.C.S.
William Thorburn, M.D., F.R.C.S.

K.C.M.G.

Surgeon-General William Babbie, V.C., C.B., C.M.G.

C.M.G.

Temporary Colonels:

Archibald E. Garrod, M.D., F.R.S.
F. M. Sandwith, M.D., F.R.C.P.
A. H. Tubby, M.B., F.R.C.S.
W. H. Willcox, M.D., F.R.C.P.

Lieutenant-Colonels:

F. Etherington, C.A.M.C.
S. H. McKee, C.A.M.C.

Temporary Lieutenant-Colonel C. H. Lindsay, M.D., R.A.M.C. (T.F.)

Major E. G. Davis, C.A.M.C.

D.S.O.

Lieutenant-Colonel E. V. Gostling, R.A.M.C. (T.F.)
Major J. G. Bell, M.B., R.A.M.C.

Military Cross.

Temporary Captain W. N. Rishworth, M.B., R.A.M.C.

NOTES.

CANADIAN HOSPITALS.

It is announced that the Canadian General Hospital, No. 7 (Queen's University Military Hospital), which is under the command of Lieutenant-Colonel Etherington, C.A.M.C., has left Cairo for England, where it will be reorganized. It is probable that it will then go to France. No. 6 General Hospital, the gift of Laval University, Montreal, recently arrived in England. This unit is under the command of Lieutenant-Colonel George Beauchamp, C.A.M.C. No. 5 Canadian General Hospital, under the command of Lieutenant-Colonel E. C. Hart, C.A.M.C., of Victoria, was recruited in the province of British Columbia, and is now stationed at Salonica.

CASUALTIES AMONG GERMAN DOCTORS.

The *Muenchener medizinische Wochenschrift* (February 29th, 1916) states that a survey of the losses among German army doctors, gleaned from the casualty lists Nos. 1 to 450, shows the total loss in the army and navy amounted to 1,164. Among these there were 264 killed, 130 died of illness, and 1 died of gas poisoning. Thus the total number of deaths was 395. Further, there were 148 severely wounded, 411 slightly wounded, 133 prisoners, 76 missing, and 1 ill.

THE GERMAN ARMY MEDICAL SERVICE.

At a session of the Prussian Lower House it was stated¹ that more than 14,500 medical men were serving in the army, and that the majority of them belonged to the reserve, the "Landwehr," or to the civilian medical profession subject to military duties. The total number of cases of cholera in the army had not exceeded 300, and in Prussia only 41 cases occurred among the civilian population. In the autumn of 1914 typhoid fever had been fairly prevalent on the western front, but early in 1916 it was practically stamped out. This change was attributed to prophylactic inoculation; so extensively had this measure been adopted, that a total quantity of 26 c.b.m. of vaccine had been used. The amount of cholera vaccine used amounted to 29 c.b.m.

¹ *Muench. med. Woch.*, March 7th, 1916.

THE *Muenchener medizinische Wochenschrift* of November 23rd, 1915, gives a list of forty-one inaugural dissertations presented at the University of Kiel during six months of the past year. No fewer than 28, or 70 per cent., dealt with neurological and psychiatric subjects.

Ireland.

WE have received no news from our Irish correspondents this week. It is to be gathered from the graphic letters of Mr. John E. Healy, editor of the *Irish Times*, that the house of the College of Surgeons of Ireland in St. Stephen's Green was made to serve as the chief ambulance dépôt or hospital of the insurgents. A number of wounded were also taken to the Royal City of Dublin Hospital in Baggot Street, which runs into St. Stephen's Green. Mr. Healy states that the first serious street fighting took place on Tuesday, April 25th, at the corner of Pembroke and Lansdowne Roads, where the rebels had seized a doctor's house, from which the troops coming from Kingstown were fired on. When the house was captured in the evening the bodies of nineteen Sinn Féiners were found within. On the same day the insurgents seized an ammunition shop, from which they had Trinity College under close and direct fire. The College was occupied by soldiers, and on Wednesday, April 26th, a field gun was brought to the roof of the College and the ammunition shop blown to pieces. In spite of all this, a term examination was carried on with the usual exactness within the walls of the College. The house of the College of Surgeons seems to have been one of the last buildings held by the insurgents, and Mr. Healy states that on April 30th there were some 200 wounded men in the building.

Scotland.

THE annual report of the Scottish National Society for the Prevention of Cruelty to Children stated that while in many cases homes were better owing to the absence of the father on service, in others women whose husbands were away had given way to excessive drinking, but in practically every instance the woman was drinking before. From a statement made at the annual meeting it appears that the preventive work of the society has been remarkably successful. During 1915 in Edinburgh alone 545 soldiers' wives had been under supervision, and it had been possible to save 500 from prosecution. The number of complaints during the year was 7,200; this was 1,653 less than in the previous year, but the welfare of 22,263 children was involved. The report expressed alarm at the great ignorance and carelessness with regard to child life in many quarters, and dwelt on the evil effect upon physical health caused by ignorance, drunkenness, dirt, and neglect. The motion for the election of the honorary secretaries made by Major C. D. Murray was seconded by Dr. James Carmichael, and adopted.

India.

MALARIA IN BENGAL.

SOME novel ideas in regard to the prevalence and spread of malaria were enunciated in a lecture given by Dr. C. A. Bentley at the Senate House, Calcutta, on swamps and floods in relation to Bengal malaria. Malaria, he said, was usually associated with the presence of swamps, and in the Punjab and in many other countries the occurrence of floods was followed by an outbreak of epidemic malaria. The physical conditions in Bengal, however, were vastly different from those of the Punjab, and what held good in one part of the country was not necessarily true of another. Bengal was very largely deltaic and swampy, but many swampy countries were practically immune from malaria, as, for example, the marshy country round Alexandria, and—until drainage was begun—the swampy delta round Ravenna in Italy. The explanation of these apparent anomalies was that the larvae of the anopheles mosquito were always found round the edges of pools, streams, etc., but never far from the edge; it was in fact the amount of water edge that governed the output of mosquitos. In Dacca, for instance, the mosquito season occurred during the dry weather, that being the season when there was most water edge; in the monsoon the

country was largely inundated, and the water edge was consequently much reduced. Reclamation of land often caused violent outbreaks of malaria, not because there was any poison in the soil, but because until drainage was thoroughly effective ideal breeding places for mosquitos were provided by the land in process of reclamation. In an average Bengal village there were numerous small depressions and hollows, and it was said that these were largely responsible for the prevalence of malaria. Yet in East Bengal, where the conditions as regards physical configuration of the soil were almost exactly similar, there was comparatively little malaria. The true explanation of this paradoxical state of affairs was that it was only in the monsoon season that malaria was conveyed by the anopheles mosquito; a large portion of East Bengal being inundated at that period of the year the number of malarial mosquitos was kept in check. In Central Bengal, owing to the fact that extensive flooding no longer occurred, every little pool during the dangerous months was a breeding place for mosquitos.

PLAGUE IN INDIA.

There were as many as 6,628 deaths from plague in the whole of India during the week ending February 5th. Bombay Presidency and Sind and the United Provinces account for 1,721 and 1,628 respectively. Other provincial figures are: Madras Presidency, 431; Bengal, 3; Behar and Orissa, 603; Punjab, 65; Burma, 350; Central Provinces, 703; Mysore State, 162; Hyderabad State, 874; Central India, 80; and Kashmir, 6.

Correspondence.

TIME IN SURGERY.

SIR,—The act of saving "time in surgery" is one that even slow operators can accomplish by avoiding unnecessary pauses, and I agree with Maylard that this is specially desirable in many cases of abdominal section. In fact, apart from the interests of the patient, which are vital, one finds that the practice comes naturally to surgeons who do many operations in a day, if only to save the time of themselves and their assistants. Even small and simple operations, requiring ten seconds, are apt to be extended to as many minutes by the evil habit of dawdling and rambling on the part of some. Quick operating, when it does not come naturally to the surgeon, can be acquired by example, and need not be accompanied by hurried movements. Though I have often erred in operating too slowly, I have also often found occasion to perform rapidly with equal ease.

The first time I attempted pylorotomy I was astonished at the simplicity of the process in that particular case, and the short time occupied in finishing it without hurry. Cases differ greatly, and some are easily and quickly done, while others are difficult and exasperating in the time necessarily spent. I have seen abdominal hysterectomy quickly and thoroughly done by surgeons at home and abroad, but never so quickly as, or more brilliantly than, by Doyen, without the slightest hurry, during the Paris International Medical Congress of 1900.

I then made the acquaintance of Professor Alex. R. Simpson, whose untimely death by accident we have had so recently to deplore. It was he who told me of a demonstration to be given by Doyen on August 8th. There was a crowd of surgeons of all nationalities, among them Collins Warren of Boston and Ernest Laplace of Philadelphia. When the audience had collected in the theatre, I found myself at the back, in the blazing heat of the window. Seeing Simpson somewhere in a bad place, Doyen said, "Gentlemen, please make room for our seniors," and placed him with Sir William MacGormac and Reginald Harrison in the middle of the front row, and I slipped in next to Harrison.

Among many operations came the abdominal hysterectomy which we four saw from a distance of under two yards. The operation was done without an instant's pause or the slightest hurry, and finished in about ten minutes, with admirable skill. In one of the intervals, while the folding doors into the corridor were wide open, I noticed a person with a camera photographing the

company. I thought no more of this till some months later, when a friend pointed to what he described as an interesting article in, I think, *Black and White* entitled "In the cause of humanity." On the opposite page was a photographic engraving illustrating the article, in which I saw objects reminding me at once of Doyen's theatre. Then I saw the patient's knees over the edge of his tilted table, and Doyen's back by her side; then Simpson seated in the middle, MacCormac, Harrison, and myself standing beside him, with the rest of the international crowd.—I am, etc.,

RUSHTON PARKER,

Professor of Surgery in the University of Liverpool;
Lieutenant-Colonel 1st Western General
Hospital, R.A.M.C.(T.F.).

Liverpool, April 30th.

THE CONTROL OF VENEREAL DISEASES.

SIR,—The main recommendations of the Report of the Royal Commission on Venereal Diseases have been received with remarkable unanimity. The proposal that facilities for diagnosis and treatment should be made freely available for every sufferer has been approved from every side, and I have not heard of any opposition or criticism. The President of the Local Government Board has indicated that at least three-fourths of the cost will be borne by the Imperial Exchequer. The path is therefore clear for general hospitals, universities, and local authorities to make their plans for carrying out the work. Whatever controversies may arise on side-issues, they must not be allowed to obscure this humane, reasonable, and much-needed reform.

With this in mind, may I briefly refer to two points which are, or may be, controversial, and which were raised by the important article in the *Edinburgh Review*, quoted in your issue of April 22nd, p. 597?

The first of these is the suggested compulsory detention of patients in workhouse infirmaries. About this proposal opinions are much divided. It would appear to be advocated chiefly on *a priori* grounds. I have searched the published evidence, and have failed to find any adequate case made out for this departure from the general lines of the report. Would it not be well to postpone any such change until a beginning has been made with the national system of free and voluntary treatment, and until we see what is to be the relation of Poor Law infirmaries to that system?

The second point is prophylaxis. On this thorny question the Royal Commission kept silence, but it is being widely discussed, and thanks are due to you for being prepared to handle it. If the application of simple germicidal remedies within a few hours after exposure to infection proves as efficacious as is alleged, their use amounts to a logical extension of that early treatment on which the Royal Commissioners rightly lay stress. In the case of an individual who had yielded to temptation, few would hesitate to give or advise such treatment. Therefore, where large numbers of men are assembled, it may be right to provide facilities for it. If, however, such provision should convey (as it might if unwisely announced) a false impression that the authorities look with tolerance upon sexual vice, this would be a disgrace to our army now, and a national disaster in the future when the men return to civil life. Such provision therefore makes it even more necessary that men should be told not only the risks of self-indulgence but also the duty and healthfulness of self-control. They should learn that the best soldier and the finest man is he who does not need to use prophylactic measures because he practises continence, which is the only absolute prophylaxis.

There is surely a clear distinction between this disinfection after known exposure, and another method referred to by the *Edinburgh reviewer*—namely, the so-called "prophylactic packet," handed to men before they leave the camp or ship. The latter plan amounts to an admission to each individual who receives a packet that he is not expected to exercise self-control. It is utterly incompatible with any sound moral or physiological teaching, and I cannot see how it can possibly fail to be an encouragement to vice.

Most thoughtful people will agree with the reviewer when he says that any widespread improvement in morals

"will be due to moral causes, not to materialistic fear of specific diseases." But improvement in morals is the only radical means of preventing venereal disease, and we stultify ourselves if in efforts to minimize the results of an evil we lose sight of its fundamental cause.—I am, etc.,
London, S.W., April 28th.

HELEN WILSON, M.D.

THE "SOLDIER'S HEART" AND ITS RELATION TO THYROIDISM.

SIR,—Besides those with a physiologically normal thyroid there are great numbers of people in whom the secretion of the gland is either more or less deficient, or more or less superabundant. The extremes are, of course, examples of myxoedema and of Graves's disease. But a deficiency or an excess may be present in such minor degree that the subjects thereof, although presenting definite symptoms upon examination, may be more justly looked upon—as, indeed, they pass in ordinary affairs—as members of a type rather than as sufferers from disease.

There is still another variation from normal in which symptoms of hyperthyroidism—especially those connected with the nervous system—are superimposed on a basal and general minor hypothyroid state (*petite insuffisance thyroïdienne*). The explanation may be that certain functions of the gland are directly diminished and others exaggerated by variations in the secretion itself, or—if the thyroid is to be regarded as the master of the whole endocrinous system—that these variations in its secretion lead to an instability of control.

The practical point is that all these people are so little removed from normal that they are readily accepted for the army if fit in other respects, and in my experience the great majority of cases of "soldier's heart" occur in patients belonging either to the "thyroid instability" type described above, or to the type of minor hyperthyroidism. One could with fair certainty undertake to reproduce the condition experimentally in members of these types by subjecting them to circumstances similar to those of the soldier's life, which result in frequent and wide variations of blood pressure—namely, prolonged and sudden physical strain, excessive tobacco smoking, mental anxiety, and shock.

I believe, therefore, that the soldier's heart is usually the outcome of submitting these particular thyroid types to such conditions, and that both the normal type and the pure hypothyroidian are far less likely to suffer.

Some principles in the general treatment of soldiers invalided with this complaint suggest themselves at once: Tranquil life in fresh air, preferably at sea level, with enough amusement to keep them from brooding over past horrors; plenty of bed and sleep—the latter procured, if necessary, by a simple hypnotic; purin-free diet; strict regulation of stimulants, including tea and coffee; restriction of tobacco, especially in the form of cigarettes, which not only, in common with all tobacco, stimulate the suprarenals, but when inhaled have a further and more direct effect upon the heart by irritating vagus terminals.

As regards special treatment, the indications are to improve katabolism and to restore cardiac tone. I know no better method of attaining both objects than by using the interrupted and reversed faradic current in the way perfected by Professor J. Bergonié, by which the skeletal muscles in their entirety may be thrown into rhythmic contraction; varied at the desire of the operator in rate and intensity, without discomfort or fatigue to the patient, without strain upon the heart, and with a beneficial effect upon the muscles themselves. The patients thus obtain the beneficial results of exercise without any effort of will or any draft whatever upon their already enfeebled capital energy, whilst at the same time the heart is helped, by the enormous stimulus to venous return, to deliver a large output against a negligible rise in pressure.

It is extraordinary how during this treatment the most excited heart will settle down in a few moments to quiet regular work, the patient concurrently losing all sense of its irritability. A period of quiescence follows and becomes longer after each sitting, and it is difficult to imagine better final results than are given by this very complete method of physiotherapy.—I am, etc.,

J. S. KELLETT SMITH.

Eastbourne, April 25th.

SIR,—Sir James Barr, in his article on "The Soldier's Heart," emphasizes the need for more calcium in the food of soldiers.

About five years ago I pointed out in the *Hospital* of February 4th, 1911, that there was this great deficiency, and I laid the matter before the Director-General, A.M.S., who replied "that a board was about to sit on the question of food supply, and that my suggestions would be put before them."

Evidently the board did not agree either with the opinions of Sir James Barr or yours truly,

Swansea, April 19th.

G. ARBOUR STEPHENS.

THE INGUINAL INCISION FOR INTRASCROTAL AFFECTIONS.

SIR,—The article by Mr. Maylard in your issue of April 22nd (p. 589) is of great interest as a reasoned explanation of the choice of site for the incision in intrascrotal affections. That the choice of the inguinal region in most such cases may not be novel he is careful to point out, and would be the first, as is well known to surgeons here, to welcome information tending to place points of surgical treatment in historical sequence. I therefore take the liberty of giving one or two references on the question.

In an article entitled "Six cases of hydrocele in infants treated by operation," published in the *BRITISH MEDICAL JOURNAL* of February 22nd, 1913, Mr. James H. Nicoll, surgeon to the Western Infirmary, Glasgow, dealt with the incision discussed by Mr. Maylard. The article was illustrated by a plate with two figures showing the hydrocele sac being pushed up into the inguinal incision. The object of Mr. Nicoll's article was not so much to draw attention to the situation of the incision (since that was made according to his practice of many years) as to give specific instances of the wide scope of operations which might advantageously be performed at an out-patient department. Mr. Nicoll has used the inguinal incision for intrascrotal affections (where the scrotal skin is sound) for about twenty years. I myself have witnessed his use of it in hundreds of cases during the past seven years.

In their *Manual of Surgery* (vol. iii, Operative Surgery, 1913, p. 578), Thomson and Miles quote Winkelmann as recommending the inguinal incision for hydrocele. These authors also recommend it for castration if the skin of the scrotum is not involved in the disease (p. 572).

Beesly and Johnston, in their new *Manual of Surgical Anatomy* (Hodder and Stoughton, 1916, pp. 262, 268) describe the inguinal incision for radical cure of hydrocele, and on p. 266 give it as an alternative to the scrotal incision for excision of the testis.—I am, etc.,

Glasgow, April 25th.

CHARLES BENNETT, M.B.

THE FEES OF GENERAL PRACTITIONERS.

SIR,—I think every one will admit that the medical profession has come forward very freely in many directions during the present crisis, but I also think that we should be justified in looking after our own interests a little, both for our own sakes and the sakes of those who are serving, and the present gives an opportunity which will never arise again to do two things—(1) to raise our fees; (2) to teach the public to allow medical men more freedom.

Expenses all around are increasing, while the fees of general practitioners in England remain grossly inadequate, and it is our own fault that they are so. My own fees are as high as the custom of the district will allow, but the other day a small local tradesman came into my surgery, remained fifteen minutes, obtained important advice as regards his health, and a bottle of medicine which cost me at least 1s., and paid me 3s. 6d., which I am sure he thought was quite enough. The next day the same man visited the dentist, remained ten minutes, had two teeth extracted, and willingly paid 7s. 6d. Could I quote a better example to support my plea that general practitioners should raise their fees, so that we might have some prospect of earning enough to retire, instead of dying in harness, as most of us do at present?—I am, etc.,

May 1st.

GENERAL PRACTITIONER.

JEJUNOSTOMY AND JEJUNO-COLOSTOMY.

SIR,—Mr. Handley thinks that the procedure I advocate for post-operative faecal or intestinal vomiting—namely, jejunostomy with subsequent restoration of the jejunum—is a more severe one than his proposal of jejunocolostomy plus caecostomy, and quotes a paragraph from my paper in support of his opinion. Quotations divorced from their context are fallacious; he should have added at least the following further quotation:

It is true that after jejunostomy a second operation to close the opening has to be faced, but this is not such a serious undertaking as might at first sight be thought.

That a risk is incurred is of course obvious; but on the other hand, Mr. Handley's proposal involves a risk in my opinion still greater—the performance of an intestinal anastomosis during a period of acute obstruction.

Mr. Handley says that caecostomy openings often close spontaneously; they do, but not by any means always. But what of the opening between the jejunum and transverse colon? Does that close spontaneously? And if it does not, to what extent is it injurious to the patient? These are questions which cannot be answered on one recently operated on case.

Mr. Handley claims that his proceeding improvises a physiologically complete intestinal canal. An intestinal canal consisting of the oesophagus, stomach, and a few inches of jejunum and colon is not physiological; neither is a communication between the jejunum and colon. He misuses the term.

He assumes that the successful result he achieved in the case published in his recent paper was due to the possession by the patient of this "physiologically complete intestinal canal." I hold that it was due to the fact that in the making of it he drained the jejunum, and that there is really no difference therefore in the *rationale* of the two procedures.

Our difference of opinion seems to me to be chiefly due to a different conception of the primary agencies underlying the symptoms of acute intestinal obstruction. As I understand him, he believes them to be situated outside the bowel (peritonitis), whereas I believe that it is to changes occurring inside the bowel that the symptomatology must be primarily ascribed, and that peritonitis is merely a common accompaniment. Thus all the symptoms may be present without any peritonitis, and, conversely, the most profound peritonitis is often seen without any of the symptoms of intestinal obstruction.—I am, etc.,

London, W., May 2nd.

VICTOR BONNEY.

WOUNDS OF JAW AND FACE.

SIR,—The papers and discussions at the annual general meeting of the British Dental Association on June 15th, 16th, and 17th (to be held at the house of the Royal Society of Medicine) will be entirely devoted to the important subject of war injuries and gunshot fractures of the jaws and the best methods of treatment. There will also be an exhibition of appliances and splints, improved and adapted for the most efficient use under the new war conditions.

May I, by your courtesy, appeal to those of your readers who have been treating cases of jaw injuries to contribute models, appliances, splints, skiagrams, etc., to the exhibition? It is particularly requested that in sending exhibits the following points should be observed:

1. The case containing the exhibit should include a note of the exhibitor's name and address, and a list of all the exhibits contained in the case.
2. That each part of the exhibit should have the exhibitor's initials attached to it by means of a small piece of gummed paper.
3. That all exhibits should reach the house of the Royal Society of Medicine, 1, Wimpole Street, W., not later than Friday, June 9th.

—I am, etc.,

F. N. DOUBLEDAY,

Honorary Secretary, Museum Committee.

19, Hanover Square, W., May 1st.

THE New York Academy of Sciences will celebrate the centenary of its foundation in May, 1917.

Obituary.

WHARTON PETER HOOD, M.D.St.And.,
M.R.C.S., L.S.A.

DR. WHARTON HOOD died on April 27th, aged 82, after a short illness, at his residence in Montagu Mansions, Portman Square, where he had lived in retirement for some years. He was the son of Dr. Peter Hood, who died in 1890, aged 81. Wharton Hood received his professional education at King's College, and held the office of house-surgeon to the hospital. He took the diplomas of M.R.C.S. in 1855 and of L.S.A. in 1856. The degree of M.D.St.And. was conferred upon him in 1862.

Dr. Wharton P. Hood will mainly be remembered for an announcement which he made in his *Bone-setting (so-called) and its Relation to the Treatment of Joints Crippled by Injury, Rheumatism, etc.*, published in 1871, four years after the appearance in print of Sir James Paget's lecture on "Cases that bonesetters cure." Dr. Wharton Hood explained in the introduction to his essay that six years previously his father, Dr. Peter Hood, in conjunction with Dr. Iles of Watford, attended Mr. Hutton, a well-known bonesetter of the day. Dr. P. Hood declined to take a fee, as Hutton had been of service to so many poor people, upon which Hutton offered to instruct him in the details of his method of bonesetting. Though this offer was declined by Dr. Peter Hood owing to stress of work, it was accepted by his son. As long as Hutton lived, Dr. Wharton Hood declined to publish, or even discuss with friends, the procedures by which Hutton treated stiff joints, but he gained additional experience while attending his poor patients during a second illness from which Hutton suffered, and after the bonesetter's death published what he had learnt. In 1875 Sir James Paget, in a new edition of his *Clinical Lectures*, said that "Dr. Hood had thoroughly learned the art, and practises it skilfully," and advised in his discourse on bonesetters' cases, that "Dr. Hood's essay should be read on all these cases, not only for the manual treatment which he teaches, but for the signs which he indicates as decisive in the choice of cases."

In 1902 Dr. Wharton Hood issued a more complete work, *The Treatment of Injuries by Friction and Movement*, in which he explained yet more fully the empirical methods which he had learnt from Hutton, and said that to the last Hutton honestly believed that the snapping noise, heard when a stiff joint was forcibly made movable, meant the reduction of a dislocation.

Dr. Wharton Hood was honorary surgeon to the Royal Academy of Music, and to two Masonic charities, and was at one time surgeon to the Royal Bucks Militia.

THE LATE DR. T. COLCOTT FOX.

DR. J. J. PRINGLE (London) writes: There is, I can confidently say, no doubt that Colcott Fox influenced British dermatology more powerfully than any of his contemporaries, and almost all of our most prominent dermatologists of the present day must be included among his pupils. Their devotion to him was justifiably unbounded, and by them shall most of his teaching be handed down to posterity. Colcott Fox's name is not associated with any startling discovery or linked on to any special disease; he wrote no popular textbook; he was too supreme and conscientious an artist to condescend to the perpetration of any professional "pot-boiler." But he traversed and illuminated the whole length and breadth of the field of dermatology and touched no subject which he did not adorn. His consummate mastery of technical detail did not militate against his breadth of conception; he saw both the trees and the wood. I was associated for fifteen years with Colcott Fox as co-secretary of the Dermatological Society of London, and during that time I learnt to appreciate his many qualities of heart and mind, his wonderful toleration of everything except humbug, pretension, or "unstraightness," and the extraordinary depth and many-sidedness of his knowledge. Had he cared to do so, Colcott Fox might have claimed priority of observation of many conditions which have been accredited to others, but his almost overwhelming generosity constrained him from doing so. No more lovable man ever existed; his friends were many and

true, and their hearts go out in deepest sympathy to his mourning widow, who guarded and guided him with such exquisite tenderness throughout the dark days of his failing years.

Dr. ARTHUR WHITFIELD (London) writes: I knew the late Dr. Colcott Fox since 1892, and for many years afterwards somewhat intimately. His personality was such that it seemed always to inspire a deep affection for him among all those whose privilege it was to work with him. There is no doubt that his teaching has had a most important influence on the English school of dermatology owing to his acute clinical observation, and his wonderful capacity for imparting his knowledge and method to his pupils. To watch him trace out the development of a difficult eruption was a wonderful object lesson in reasoning and observation. Nothing seemed ever to escape his eye, and his touch would tell him almost unfailingly the nature of the tissue beneath his finger. He had also a vast knowledge of medical literature, and this was always at the service of his younger colleagues. In many cases the best clinical descriptions of the less common diseases of the skin are still those written by Colcott Fox. Never a showy man he was almost worshipped by his patients, and at both the Westminster and Paddington Green Hospitals, where I had long opportunities of working with him, it was a recurring pleasure to watch his cheery and sympathetic treatment of them. Outside his profession he was widely read in most good English literature, and it was a wonder to me how his memory could retain so accurately all the various oddments with which he filled it. At heart he was always a lover of the country, and I well remember his saying to me that a Hampshire lane with the wild rose (which he liked to call by the old name of eglantine) in blossom appealed to him as the most beautiful sight he knew. He was a thorough sportsman, a first-class cricketer and oar in his younger days, an excellent skater, a good shot, and in later years a golfer above the average. Always kindly and considerate, the only thing I knew that could rouse his temper was a mean or contemptible action. By the death of Colcott Fox England has lost one of her finest types of gentleman, and dermatology one of its best exponents.

DR. FREDERICK LEVER of Montpellier Lodge, Harrogate, died on April 15th in his 69th year. He was the son of Mr. Benjamin Lever of Blakesley, Northamptonshire, and was educated at Epsom College and Guy's Hospital, where he took the Sands-Cox Scholarship in 1882 and the B.Sc.Lond. with honours in the same year. In 1885 he took the diploma of M.R.C.S. and the degrees of M.B., B.S.Lond. For thirty years Dr. Lever practised in Harrogate, and from first to last was most zealous in urging its advantages—social and medical—as a spa. As late as in 1908 he wrote an article on the properties and therapeutic uses of the Harrogate waters in the *Balneological Journal*. From the commencement he was a prominent member of the Harrogate Medical Society, of which he was twice president. He leaves a widow, one son, and one daughter.

DR. THÉODORE GUILLOZ, professor of electro-therapy in the Medical Faculty of Nancy, recently died at the age of 48. He took his degree at that university in 1893, and became *agrégé* in 1895. He took up radiology as a speciality and settled in Paris, where he was very successful. But he fell a victim to his zeal in working at the improvement of α -ray apparatus and the practical applications of the method. He had to submit to amputation of several fingers, and was awarded the Carnegie gold medal as a martyr of science. In 1906 he was appointed professor at Nancy, and in recognition of the value of his inventions shown at the exposition held in that city in 1909, he received the Cross of the Legion of Honour. On the outbreak of the war he established seven stations of radio-stereoscopy at Nancy; early in 1915 he was appointed chief of the service of radiology of the 20th and 21st legions, and quite recently he was named *médecin-major de 1^{re} classe*. Although very ill he went on with his work, and devised an apparatus for the localization

of embedded projectiles and a needle for finding the foreign body. He died at Lyons, where his duty had called him.

LIEUTENANT-COLONEL HENRY JOSEPH O'BRIEN, R.A.M.C. (ret.), died at Queenstown on April 16th. He was educated at Trinity College, Dublin, where he graduated A.B. and M.B. in 1864, and B.Ch. in 1865. He entered the army as assistant surgeon on October 2nd, 1865, became surgeon on March 1st, 1873, surgeon-major on October 2nd, 1877, and retired as brigade surgeon lieutenant-colonel on June 30th, 1896. He served in the Afghan war in 1878-80, receiving the medal.

The Services.

INDIAN MEDICAL SERVICE.

OFFICERS RETAINED.

THE Government of India has decided that lieutenant-colonels of the Indian Medical Service specially selected for increased pay, who are retained in the service on account of the war after attaining the age of 55, should be treated as supernumerary on the list, and that promotions should be made in their place with effect from the dates on which they attain that age. In the case of officers who have been granted extensions to complete thirty years' service for pension, and who are similarly retained in the service, promotion will be made from the date following that of the expiration of the period of extension.

EXCHANGES.

M.O. Wessex Division, at present under canvas at Hursley Camp, would like to exchange with Territorial M.O. serving in Portsmouth district. Address No. 1750, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

M.O. in Field Ambulance (T.F.), near London, gazetted Captain January, 1916, wishes exchange with medical officer on active service in any capacity. Address No. 1700, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

At a meeting of the University Court on April 24th it was resolved to accept the bequest by Sir William Turner of his bust by Mr. Herbert Hampton, and to place it, as the testator requested, in the Anatomical Museum of the university near that of Professor John Goodsir.

The Court finally approved the regulations already approved by the Senatus for the prize for women medical students to be paid out of the balance of the funds received from the Scottish Association for the Medical Education of Women. It will be awarded to the M.B., B.S. considered the most distinguished woman student of the year.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 27th, Dr. Frederick Taylor, the President, being in the chair.

Admission of Members. The following candidates, having passed the required examination, were admitted Members of the College:

Alexander Greig Anderson, M.D. Aberd., Rowland Hill, M.D., Queen's Univ., Belfast, William MacAdam, M.D. Glasg., Henry Harold Scott, M.D. Lond., L.R.C.P.

Licences.—Licences to practise physic were granted to ninety-nine gentlemen who had passed the requisite examinations.

Election of Fellows. The following Members were elected Fellows of the College:

Michael George Foster, M.D. Camb. (Harrogate), John MacLeod Hendrie MacLeod, M.D. Aberd., Henry Lawrence McKisack, M.D. Roy. Univ. (Irel. (Belfast), Joseph Arthur Arkwright, M.D. Camb., Charles Hewitt Miller, M.D. Camb., Harold Waterlow Wiltshire, M.D. Camb., Charles Ernest Lakin, M.D. Lond., Edward Alfred Cockayne, M.D. Oxfr.

Resignation of Representative.—A letter was received from Sir Wilnot Herringham resigning the office of representative of the College on the Governing Body of the University of Sheffield.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST EXAMINATION.—J. Campbell, J. I. Coventry, Agnes M. Hill, E. R. Lloyd, J. C. Meek, W. M. Reid, F. J. Stevenson, Marguerite M. I. Swanson.

SECOND EXAMINATION.—R. G. Bell, S. H. Waddy, M. J. Woodberg.

THIRD EXAMINATION.—R. Austin, A. Balfour Black, D. M. K. Black, J. Calder, Jean M. M. Crawford, R. P. Crawford, J. T. Dior, G. A. Grandseult, R. D. Howat, L. W. Hughes (with distinction), E. G. Jones, J. Michaelson.

FINAL EXAMINATION.—W. P. H. Lightbody, J. P. Mathie, J. R. B. Robb, A. Morison, T. Jackson, A. Smith, jun., J. McCartney, R. H. Rattray, T. M. Metcalfe.

Medical News.

DR. JOHN WYLLIE, Emeritus professor of medicine in the University of Edinburgh, left estate valued at £15,589.

IT is proposed to reorganize the hospital department of Sing-Sing prison, New York, so as to include a clinic and a bureau for medical research.

AT the meeting of the Medico-Psychological Association to be held at 11, Chandos Street, W., on May 16th at 2.45 p.m., a paper, illustrated by lantern slides, will be read by Dr. Orr and Major Rows, R.A.M.C., on experimental toxic lesions in the rabbit's brain and their bearing on the genesis of acquired idiocy and imbecility in man.

As a tribute to the memory of Miss Edith Cavell, the name "Mount Cavell" has been given by the Canadian Government to one of the peaks in the Canadian Rockies. Mount Cavell rises to a height of over 11,000 feet, and is situated in the province of Alberta, near the famous Jasper Park.

THE Director-General of the Army Medical Service will preside at a meeting to be held at the Royal Army Medical College, Grosvenor Road, S.W., on Wednesday next at 3 p.m. in connexion with the proposed formation of benevolent societies for the benefit of families of officers and other ranks of the medical services auxiliary to the regular Royal Army Medical Corps—namely, the Special Reserve, the Territorial Force, and New Army. It is intended that funds shall be raised by voluntary subscriptions, and it has been proposed that each branch of the service should appoint a committee of five to seven members to administer its own funds. It is hoped that as many officers as possible will attend the meeting.

MEDICAL men share with other users of motor cars in the difficulty of obtaining chauffeurs, but it is a more serious matter for them, since the medical car is not merely a convenience or a luxury, but a necessity for the proper conduct of practice. Numerous inquiries have been received by the British Medical Association, and it has been ascertained that the Automobile Association and Motor Union have a list of men eligible as chauffeurs. Some of them are men who have been discharged from the army, others are Belgians, and nearly all are ineligible for service. Inquiries should be addressed to the Engineers Department, Automobile Association and Motor Union, 8, New Coventry Street, London, W. It is particularly requested that if any engagement is made as a result of such inquiry the Engineers Department should be informed.

AN exhibition of Japanese charms, amulets, votive offerings, and objects of medical interest was opened at the Wellcome Historical Medical Museum on May 4th. The collection, which is lent by Dr. W. L. Hildburgh, a well-known American antiquarian, consists of objects in popular use in Japan for securing protection against evil spirits and against accidents of all kinds. The collection of charms used in the cure and prevention of illness and in connexion with pregnancy and childbirth is particularly numerous. The votive offerings presented to shrines in gratitude for relief obtained are mostly symbolical paintings of various diseases. There is a small section of phallic emblems, and many specimens of printed paper charms, issued by Buddhist or Shinto temples throughout Japan, intended to protect against specific troubles. The collection, though not large, offers not a few features of interest to doctors as well as to archaeologists and anthropologists. It also makes an appeal to those to whom nothing human is foreign as representing in quaint and pathetic form the efforts of man to safeguard himself against the dangers in which he lives and moves and has his being.

OWING to the great demand for munitions in Austria, workshops have been overcrowded and overtime has been worked. The women and girls swept into this industry have not proved as immune to the wear of industrial life as the old factory hand. Professor Oppenheim (*Wien. klin. Woch.*, November 25th, 1915) states that the cases of industrial poisoning in munition factories were most numerous between the outbreak of the war and April, 1915. Their number was then greatly reduced by hygienic reforms and a more careful adaptation of employment to capacity. Professor Oppenheim gives details of twenty-six cases of dermatitis, most of them from the same factory in Vienna. In eighteen of these the disease was caused by fulminate of mercury. In a few cases the symptoms were traceable to the cleaning and polishing of metals with petroleum, ammonium chloride, acids, turpentine, and benzol. In a certain number of cases, alcohol, antimony, potassium chlorate, glue, and nitric

acid were suspected of aggravating the dermatitis. In the workers suffering from mercurial poisoning, the principal symptoms were oedema of the face and of the backs of the hands; a nodular, vesicular, or pustular eruption, which was less common, was apparently the result of a relatively slow process of poisoning. Oedema of the face was often preceded by inflammation of the eyelids and lips, and mercurial stomatitis was not rare. It was, however, ulcerative only in one case. The majority of the patients were young women, and in many of the cases mercury was found in the urine. All the symptoms disappeared quickly when the patients were relieved of their work, and they were fit for work again in a week or two. When systematic dental hygiene was adopted, and other precautions taken to prevent the absorption of mercury by the skin and mucous membrane, the number of cases began to wane, but in the winter began to increase again owing presumably to less efficient ventilation during the colder weather.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

L.R.C.P. asks for advice in the treatment of a case of leucoderma.

INCOME TAX.

A. B. explains that his partner died in February, 1915, that the executors refused to sell the book debts, and that he has paid income tax on all the receipts for 1915. He asks whether he can deduct income tax when handing over to the executors those receipts to which they are entitled.

* * The answer is in the negative, as from the date of dissolution of the partnership—presumably in February, 1915—"A. B." appears to have become the sole proprietor of the practice, and thenceforward was liable to income tax on the full annual profits of the practice, measured either by average cash receipts or by a year's bookings less bad debts. He has accordingly paid for the financial year 1915-16 no more tax than is properly due from him as proprietor of the practice. As regards the debts now being realized and handed over to the executors, the view of the Revenue authorities appears to be that, on the assumption that a full normal income has been assessed in the past, such receipts have already been subjected to income tax, and are not taxable in the hands of the executors.

G. D. K. B. is engaged on work somewhat in the nature of "military duty," inasmuch as he has undertaken additional civil work to release another surgeon for service, and, in addition, is assisting in the work of the local Voluntary Aid Detachment Hospital under military authority. He inquires whether he can on these grounds claim any special rebate or allowance in respect of income tax.

* * The question is dealt with in Section 13 of the Finance Act, 1914 (Session 2), by which the relief in question is confined to members of the military or naval forces of the Crown, or persons serving in any work abroad of the British Red Cross Society or of the St. John Ambulance. From the particulars furnished by our correspondent it would appear that he could not maintain a claim under the section referred to.

PETROL LICENCE DUTY.

T. H. E. occasionally takes his wife and two children with him on his rounds. He has been told by the local police authorities that if this continues the full licence duty must be paid, their view apparently being that only the chauffeur

and, as occasion may arise, a nurse can properly be carried in a car paying half licence duty.

* * Section 86 (4) of the Finance (1909-10) Act, 1910, provides that the allowance shall be granted "if a duly qualified medical practitioner proves to the satisfaction of the Commissioners or council by whom the licence is granted that any motor car kept by him is kept for the purpose of his profession." We cannot see that the occasional use of the car as mentioned by our correspondent could possibly disprove—what, indeed, seems fairly obvious—that the car is "kept for the purpose of his profession." Perhaps "T. H. E." may feel inclined to submit a full statement of the facts to the Commissioners of Customs and Excise, Custom House, E.C., a course which would, no doubt, free him from the present irritating position.

JUNKER ON JAPANESE OBSTETRICS.

A CORRESPONDENT wishes to know if any reader of the JOURNAL possesses a copy of a work by Dr. F. Junker on Japanese obstetrical instruments used before the introduction of European appliances, or knows where that book can be seen. It was prepared by Dr. Junker when he was principal of a medical school in Japan, and some instruments were presented to the museum of the College of Surgeons in 1878 by the author, with a copy of his treatise, but it has been lost.

ANSWERS.

PRURITUS OF THE FACE.

DR. G. W. SEQUEIRA (London) writes: In answer to "Country Doctor's" request (p. 640) I would suggest that, as there are visible changes in the skin—"subcuticular roughness"—the pruritus is not a pure neurosis. It is probably allied to Hutchinson's summer prurigo, which generally begins in childhood and lasts into the twenties, and affects the face, ears, neck, or arms. The itching sensations are due to the irritation of papillary nerves by the suddenly developing, although extremely minute, inflammatory product (serum). In this circumscribed prurigo the patients are often nervous, anxious, and worried, and it is sometimes associated with asthma, hay fever, and other bronchial affections, as well as with uterine disorders. Thus any derangement of the general health which may be present must of course be corrected on general principles. An ointment of beta naphthol, 5 per cent. strength, rubbed on the affected parts is likely to prove useful.

LETTERS, NOTES, ETC.

A VOLUME entitled *Collected Papers on Analytical Psychology*, by C. G. Jung, M.D., LL.D., authorized translation edited by Dr. Constance E. Long, has recently been published by Messrs. Baillière, Tindall, and Cox. The text occupies 377 pages. In a list of books issued by Messrs. Lewis the volume is, we are informed, described as translated by Dr. Constance E. Long. On this Dr. M. D. Eder writes to state that "of nine papers (263 pages) especially translated from the German for this work six (227 pages) were done entirely by my wife and myself; a further two (26 pages) were completely revised and partly retranslated by myself." We have received from Dr. Constance Long a note in which she writes: "My share in the book is merely that of editor; only one paper, and that from the French, being translated by me. Five different persons have contributed translations from the German, but, as Dr. Eder says, he and his wife have done the lion's share, for which they have been paid the usual translator's fees."

MEDICAL REFEREES TO INSURANCE COMPANIES.

A MEMBER writes: May I call attention to a system which seems to me ridiculous—namely, that however many medical practitioners there are, say, in a small town or country district, some insurance companies will only appoint one solely as their medical examiner? If A. holds such an appointment, and B. and C. are practising in the same town, it is clear to all that if, wishing to join a certain society, the candidates must be examined by A., though they may be patients of B. or C., which I hold to be most unfair to the latter. Now that the yearly meetings of branches are coming on, it would be a good thing to have the matter placed on the agenda and discussed. Perhaps local secretaries will take the hint, and my letter may bring forth the views of others on this subject.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

GERONTAL CONSTIPATION AND ITS TREATMENT.*

BY

W. AINSLIE HOLLIS, M.D.,

PAST PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

ETIOLOGY.

A. Prostatic Enlargement.

It has been estimated that 30 per cent. of men over 60 years of age suffer from hyperplasia of the prostate. If to these sufferers we add others in whom a very large prostate "may give rise to no appreciable symptoms,"¹ and may consequently remain undiscovered, the total percentage of elderly men in whom this organ is abnormally large is probably still higher. Situated as the prostate is between the bony unyielding symphysis and the rectum, any general enlargement of the organ exerts a flattening pressure upon the gut where it is in relation with the sacrum and coccyx. The gerontal tumour will be in the upper rectum just below the sigmoid flexure, and close to one of the usual sites of intestinal stasis. During the act of defaecation the plastic contents of the lower colon require a free passage into the rectum. A comparatively slight obstruction at this point may lead to a serious block.

B. Ineffective Peristalsis.

Recent investigations suggest that, so far as the propulsion of its contents is concerned, the alimentary canal can be divided into a series of sections, each of which, through its neuro-muscular apparatus, forms a more or less independent zone of rhythmic contractions. Seemingly these movements start vigorously as a rule at the upper junction of a zonal area and fade away gradually towards the lower one. As regards the automatism of the rhythmic contractions, the parts of the digestive tract situated near the orifices are least automatic in character, and most under the influence of the cerebro-spinal co-ordinated reflexes. On the other hand, the rhythmic movements of the central, that is, the jejuno-iliac, segment of the bowel probably furnishes "the only example known so far (1900) of a true co-ordinated reflex dependent entirely on peripheral nervous structures."² It is well known that in the neuroses associated with senility "disassociation follows the usual law of degeneration, and passes progressively from the unstable to the stable, from the less organized to the more organized, and from the less to the more automatic."³ In accordance with this law (?) the intestinal mid-segment will be the last to yield its automatism to senile decay, and so perhaps it is. On the other hand, stasis, with or without distension of the lower colon, and spasmodic contraction of the gut immediately above the obstruction, is a common result of this disorder. By the position of the cord-like tumour—representing the contracted bowel—whether it is above or below the splenic flexure, the severity of the obstruction can be to some extent gauged by the medical attendant.

C. Dryness of the Intestinal Mucosa.

A comparatively small prostatic tumour, situated near the junction of two rhythmic zones, might presumably cause stasis. Recent researches suggest that one of the functions of the colon is the absorption of water.⁴ Undue dryness of the faecal accumulation within the lower bowel will follow prolonged retention. "Peristalsis," and its analogue "vermiculation," can only be carried on so long as the two glissading surfaces—namely, that of the living tube and the side of the inert material adjacent to it—are freely moistened. The earthworm, for instance—to take a well-known *Oligochaeta*—forms its tunnels in moist and plastic soil.⁵ Although well provided with segmental nephridia with which it excretes a fluid to lave its epidermal coat, it rapidly withers and dies when placed on dry soil. Our intestines, although they, too, are provided with excretory crypts (Lieberkühn's), that produce the succus entericus, lavage the mucosa, yet cannot satisfactorily propel hardened scybala through the bowels. In neither of these two cases of rhythmic contractile movement can progressive or propulsive results be fully brought about, unless and until the inert material is in a condition

to react to the constrictions of the living tube; in other words, that material must be plastic, and, as a consequence, moist. Unfortunately, as above mentioned, old men are handicapped in two directions as regards this necessary accompaniment to a satisfactory peristalsis. Owing to the delay that so often occurs at the recto-sigmoidal juncture not only are the faeces dry, but the mucosa of the lower rectum at all events is usually abnormally dry also. Perhaps a dryness of the inner membrane of the gut may be in some cases general throughout the colon. However this may be, the dryness leads to excessive straining at stool, and may also account for the comparative frequency with which "volvulus" of sigmoid affects old men,⁶ the twisting of the gut being an immediate consequence of an overstrain.

Historic Precedents.

There are certain incidents which recur in the history of patients who suffer from this disorder, and recur with sufficient frequency to justify an inquiry as to whether or no there may be some causal relationship between them. After the age of 45 dietary indiscretions, undue sexual excitement, and inattention to the regular action of the bowels are, in my experience, the most usual coincidents. As regards the first, old men have long had a reputation for enjoying the pleasures of the table. Indeed, the ancient Greeks, who revered the antique, set aside special vintages for their consumption. They even coined a word—"gerousios"—to label this *alcohol olus*, this sparkling wine, as Homer calls it.⁷ Moreover, they took care that the "gerousios oinos" was only drunk at these aldermanic carousals. The similarity of the spelling of the Greek word "gerousios" and its English equivalent (in that case) suggests to my mind a derivational relationship—an opinion not presumably held by the expert compilers of the Oxford *New English Dictionary*. Still, the reputation of the "aged, aged man a-sittin' on a gate" concerns us only so far as it indicates that the above mode of life favours the development of the disorder in question. I think that it does so in two directions. One of the commonest signs of good living when the first bloom of youth has "faded and gone" consists in an increasing girth of the lower *torso*. A tendency to corporeal expansiveness may in some cases be heritable; but, even so, careful dieting with a goodly proportion of fruit and total abstinence of alcohol will frequently check the tendency. It will also assist in checking the excessive straining at stool, and so prevent the early onset of "irritable heart," in my opinion the second most annoying symptom of gerontal constipation, and one which we shall subsequently find is by no means an uncommon accompaniment of the disorder.

Apart from the other historic incidents, the learned Hebenstreit informs us in his book, *De homine sano et aegroto* (1753), p. 158, that men lose their youthful vigour later in life than do women:

Senior est maribus languor, viridisque senectas
Sufficit ad validos motus, et sepius illis
Grata juventutis facies intermitet annis,
Et Veneres illis ridet Charitumque cohortes, etc.

But even they eventually die of *marasmus*, a drying up. Meanwhile they suffer (according to the equally learned Rieger), oft "from an accumulation of humours in the big vessels . . . whence their stases and stagnations, etc." Indeed, the latter commentator draws a very complete picture of an old man affected by gerontal constipation. Rieger even mentions "palpitation" as a common accompaniment of this condition. He also says that "coctio debilitatur," digestion is enfeebled, and furthermore, we may get among other troubles, "dysuria, stranguria, calculus, ischuria," and so on.⁸

SIGNS AND SYMPTOMS.

I shall not attempt to describe in detail the many disorders that are supposed to circle around a diseased prostate. Suffice it to say that the most serious are distinctly surgical in character. Nevertheless there are symptoms which may be considered as specially diagnostic of gerontal constipation, and these we must explain in some detail.

It would seem that some, perhaps a majority, of the cases of simple enlargement of the prostate begin with venous congestion. A serious change in the blood supply

* Gerontal, from Greek *geron*, old man. Gerontal constipation means a disorder of senility affecting men only.

of the gland, which such a circulatory failure implies, would alone suggest the probability of some central (cardiac) causation, either organic or functional, and this conjecture is strongly confirmed if, as is often the case, we find the venules of the face, the nose in particular, also affected. When this is so, the elderly patient also suffers, as a rule, from those interesting, though to the ordinary general practitioner somewhat intricate, symptoms suggesting an "irritable heart," only to be fully diagnosed by an expert in such matters, aided, it may be, by some wonderful electric devices with numerous dial faces and leather straps. The most relevant discovery in this regard is, I take it, the close histological relationship that has been noted between the structural elements constituting the so-called mesenteric plexus (Auerbach's tissue) and "the nodal tissue in which the heart beat arose and the bundle by which the impulse was distributed in the heart."⁶ Experience shows that Rieger was right in giving prominence (about two centuries ago) to the fact that old men often suffered from palpitation. Tachycardia, dropped beats, irregular action of the heart, are frequently secondary to the intestinal stasis of gerontal constipation. Another anomalous symptom, by no means unusual, is probably due to the direct influence of the rectal tumour. It consists in a feeling of distension in the upper rectum, just as though a scybalon had lodged there and might at any moment descend into the trousers.

TREATMENT.

After all, the true worth of a medical treatise is best gauged by the efficiency of the prescribed treatment in bringing about, if not the cure, at all events the relief of the disorder. It is here, then, that an author has an opportunity to display his mother wit to the best advantage. "But, as Yak the Metaphysician hath written:

The wits are a dog that 'tis easy to call
but to cudgel him proveth another affair;
for shouts and abuse
are no manner of use
and unless he agrees, it is safe to declair
that the cudgelling process won't happen at all."¹⁰

The present writer feels the difficulty in this regard, and therefore offers the following suggestions with due diffidence.

The treatment of gerontal constipation can be best considered under three heads: Medicinal, dietetic, and manipulatory. So far as drugs in general are concerned, it is evident that their action can at best be only palliative. Within these limitations and as a preventive of a colic block doses of the aromatic syrup of cascara are very useful. The drug, as is well known, "acts principally on the large intestine and empties the rectum. It is suitable for delicate and elderly persons."¹¹ It would seem probable, from the action of this drug, that some constituent of cascara sagrada acts specially on the mesenteric neuro-muscular plexus in the colon and so stimulates the rhythmic movements. The medicine ought to be given in a full dose directly any falling off in quantity or quality of the daily evacuation is observable. The treatment of the senile heart is, in my experience, best effected by small doses of the tincture of strophanthus in a little water, to which a few grains of sodium bicarbonate have been added. This mixture may be taken three times daily, about half an hour after a meal. It was recommended some years ago by a correspondent of this JOURNAL as a useful palliative of this condition.

As regards diet, I have already drawn attention to the value of fruit; here I need merely add that the ordinary rules regarding the modified requirements of the aged man for meats and the satisfactory mastication of food should be in all cases carefully observed. Dental hygiene is also very important, knowing as we now do, thanks largely to the American dentists, how the flora and fauna of pyorrhoea flourish in the uncleanly mouth. The less stimulant the old man absorbs the better his ultimate chance of longevity.

We now come to what is in many respects the most important part of this paper—that is to say, the part where the "cudgelling process" of the writer's brains is mostly required. When by daily increasing strain the old man begins to perceive that a visit to his doctor is imperative, much mischief may already have been inflicted upon the mucosa and blood vessels about the anus. In the treat-

ment of gerontal constipation cleanliness is undoubtedly the most important manipulative procedure. Congested piles, rents in anal mucosa, commencing prolapse, all rapidly yield as a rule to a régime of cleanliness. But in order that the hygienic procedure may produce the maximum effect, it must be started early. When there is much straining at stool, the gerontal right index-finger, well guarded, it may be, with two or three thicknesses of tissue paper, should be pressed upon the perineum just behind the symphysis, and so relieve the abnormal pressure of an enlarged prostate upon the rectum.

SARCOMA OF FRONTAL LOBE GIVING RISE TO OCULAR SIGNS ONLY.

By R. BEATSON HIRD, M.D., F.R.C.S.E.,

CAPTAIN R.A.M.C.(T.F.),

OPHTHALMIC SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM;
ASSISTANT SURGEON TO THE BIRMINGHAM AND MIDLAND
EYE HOSPITAL, ETC.

THE case here reported must belong to a rare group of cases, and the record is therefore of interest.

The patient was a bricklayer, aged 34, who was admitted under my care at the General Hospital, Birmingham, on October 27th, 1915, having been under observation as an out-patient for two weeks previously. He had suffered from rheumatic fever at the age of 19, and had had an attack of gonorrhoea at the age of 25. Otherwise his health had been good down to within a few months. There was nothing in his family history of any note.

History.

About four months ago he noticed that almost every night he was kept awake by a pain in his right eye, giving rise to the sensation "that his eye was being pulled out." During the day very little was noticed, but towards evening he experienced shooting pains. About a month later he noticed the right eye becoming prominent. He then sought advice at a local hospital. Since then his condition had grown worse, until he was unable to open the right eye properly. He described his head as being "muddled at times." He stated that he had never seen double.

Physical Signs.

There was a moderate degree of right exophthalmos, and the eye was also displaced downwards and a little outwards. There was considerable though not complete ptosis, the frontalis muscle being used when an attempt was made to open the eye. The roof of the orbit appeared to be filled in, and lower than normal. It was firm to touch and not painful.

Corneal sensation was good, and the pupil reactions normal in all respects. Sensation was not quite normal over the area supplied by the supraorbital nerve.

The right fundus showed marked optic neuritis with a fair degree of swelling; there were some retinal haemorrhages in the region of the disc, and the retinal veins were engorged. The left fundus showed early optic neuritis; the upper and lower edges of the disc were blurred and a little swollen, and there was a retinal haemorrhage near the upper part of the disc. The optic neuritis was of the increased pressure type.

* Hippocrates flourished in Greece in the fifth century before Christ. Among other discoveries, he announced to the world that the bald were not usually afflicted with varicose veins (*Aph. vi, 34*). He also presented the Royal College of Physicians of London with a motto, which many read and few understand. Indeed, the most plausible translation was one made by a disappointed Fellow. It was as follows: "The patient's life was short; but then the surgical technique was great!"

My colleague, Mr. Woodman, made a thorough examination of the nose and accessory sinuses. Transillumination showed nothing pathological, and there was no evidence of any intranasal disease. The pharyngeal ends of the Eustachian tubes were enlarged and oedematous. A radiograph showed nothing definite, but the orbital roof on the right side was not as well defined as on the left.

There was a faint haze of albumin in the urine. The Wassermann test was negative. The pulse-rate was normal, but fell once after admission to 64. The temperature on admission was 99.4°, and afterwards fluctuated between 97° and normal. He was admitted with the diagnosis of orbital growth, probably sarcoma growing from the region of the sphenoid.

There was never any sickness nor complaint of any headache. He died on November 5th with typical respiratory failure. For about forty-eight hours before death he was rather peculiar mentally, and got up during the night and wandered about the ward. He never displayed any general symptoms to suggest intracranial trouble.

Post-mortem Examination.

I was present at the post-mortem examination, which was made by the pathologist, Dr. L. Walker. No abnormality was found apart from the central nervous system and orbit. The meningeal coverings over the orbital surface of the right frontal lobe of the brain were almost a quarter of an inch thick. The membranes were vascular and adherent both to the brain and roof of the orbit. The bone here, as well as in the neighbourhood of the nasal sinuses, was eroded, soft, and friable, being largely replaced by fibrous-looking tissue. The orbital roof was considerably displaced downwards. Tissue of fibrous character was present in the orbital cavity, involving the contents. There was nothing present definitely resembling sarcoma. The nasal cavities were quite healthy. Tissues from the orbit were removed for microscopical examination, and the brain removed and hardened in formalin. The orbital surface of the frontal lobe was very firm, and a piece was removed for microscopical examination. When the hardened brain was examined, the right frontal lobe was found to contain a tumour about the size of a Tangerine orange; the swelling projected mesially and caused a considerable depression in the left frontal lobe. The edge of the growth was ill-defined, and there was no capsule. Microscopically, it was a typical round-celled sarcoma, and the tissues removed from the right orbit showed a sarcomatous infiltration of the same nature. In my opinion the growth started in the brain and extended to the orbit.

In the *American Journal of Obstetrics* for October, Foskett reports the case of a single woman, aged 22, employed in an hotel, who was advised to take a bichloride douche. She dissolved three tablets of 7.3 grains each in a cup of water, and used a whirling spray syringe for the douche. At once a severe local burning sensation was experienced, and the patient went to a physician, who promptly ordered albumin water to be taken by the mouth; douches and ointments were prescribed for the external parts. Three days later Foskett was called in, and found the vagina and vulva covered with a white slough; the mucous membrane of the mouth, uvula, and pharynx was likewise white and sloughy, and there was salivation. For the first few days there was almost complete suppression of urine; what was passed contained albumin, and granular and hyaline casts, but no mercury could be detected, nor could any trace of that metal be found in blood taken from a vein. Hot packs were applied every six hours, and high colon irrigations were employed four times daily; saline aperients given by the mouth caused free catharsis. The patient, in spite of all care, became worse; bleeding from the mouth and epistaxis occurred on the fifth and sixth days, and separation of sloughs and haemorrhage from the vagina on the seventh, with dysphagia and hiccough. Blood clots were vomited on the ninth day and the throat was sore, and the fauces oedematous from separation of sloughs. The mental condition was bad, the patient being irrational and restless. The urine was excreted in normal quantities but could not be retained. There was more haemorrhage from the mouth and vagina, and on the eleventh day melaena was observed, and recent clots were also passed from the bowel. Haematemesis followed, and the patient died early on the twelfth day. In many other recorded instances of poisoning when bichloride had been used for douches in the puerperium and in operations on the pelvic organs, salivation was absent but profuse diarrhoea occurred.

Notes on Military Orthopaedics.

II. ON SUTURE OF NERVES, AND ALTERNATIVE METHODS OF TREATMENT BY TRANSPLANTATION OF TENDON.

BY

LIEUTENANT-COLONEL ROBERT JONES, CH.M.,

F.R.C.S.I. (HON.),

INSPECTOR OF MILITARY ORTHOPAEDICS, ARMY MEDICAL SERVICE.

(Continued from p. 643.)

In the first part of this paper I considered some general principles which should guide the surgeon in the treatment of limbs disabled by injuries involving nerves. I pointed out the importance of giving the muscles ample time and opportunity to recover by keeping them in a relaxed position for a sufficiently long period, and I began the discussion of tendon transplantation as an alternative method of treatment where nerve suture was not possible. I now propose to consider the transplantation operations my experience leads me to recommend in various injuries.

UPPER LIMB.

Irreparable Injury of Musculo-spiral Nerve.

1. In cases of musculo-spiral injury the deformity is a dropped wrist, with loss of the power of extending the fingers. The uncontrolled action of the flexor group causes the fingers to curl into the palm, and the hand to become useless.

In such a case:

- (a) The flexor carpi radialis and the flexor carpi ulnaris can be transplanted into the paralysed extensor of thumb and fingers; and
- (b) in addition the pronator radii teres may be affixed to the two radial extensors.

Transplantation of Pronator Radii Teres and the Radial and Ulnar Flexors in Musculo-spiral Paralysis.

I would recommend for this condition of musculo-spiral paralysis the double operation (a) and (b), and I will briefly indicate the method of its performance.

With the forearm midway between pronation and supination an incision is made along the radial border of the forearm in its middle third. Under cover of the tendon of the supinator longus the pronator radii teres will be found where it becomes inserted into the outer border of the radius. From this it is detached, and is then inserted into the tendons of the extensor carpi radialis longus and brevis, which lie closely applied to it on the dorsal surface.

A horseshoe incision, with the convexity resting on the back of the carpus, with the two straight sides extending along the radial and ulnar borders, is now made. Through the lateral aspects of this incision the tendons of the carpi ulnaris and radialis are identified, and are detached from their insertion as near the carpus as possible.

The tendons are brought round the ulna and radius respectively in very slanting fashion, and are then attached to the extensors of the fingers and thumb, the carpi ulnaris being attached to the tendons of the three inner fingers and the flexor carpi radialis to those of the thumb and index finger. The method of fixation should be neat and workmanlike.

Injury to Median and Ulnar Nerves.

In the case of great damage to the median and ulnar nerves, operations on tendons alternative to those on the nerves will be very rarely required as compared with those on the external popliteal and the musculo-spiral, for the reason that by means of flexion of the elbow a gap of two or three inches in the median may be closed up; by flexing the elbow and displacing the ulnar to the front a similar space in this nerve can be obliterated. End-to-end suture, therefore, is much more easily secured in these two nerves than in the case of the musculo-spiral and external popliteal.

In cases of complete and irreparable paralysis of the muscles supplied by the median nerve the only active muscles on the flexor aspect of the forearm are the flexor carpi ulnaris and the inner half of the flexor profundus digitorum.

Operation of Transplantation of Tendons in Median Paralysis.

(a) The outer tendons of the flexor sublimis are inserted into the inner tendons of the flexor profundus digitorum.

(b) The inner tendons of the flexor sublimis are inserted into the tendon of the flexor carpi ulnaris. The extensor carpi radialis longior is attached to the flexor longus pollicis.

Method.—A curved incision is made convex downwards with the apex just above the anterior annular ligament of

FIG. 8.—Tendon of peroneus longus divided in its course, and identified at the outer border of the foot.

FIG. 9.—Tendon of peroneus longus drawn out through the lower incision.

the wrist. After retracting the flexor sublimis tendons, the outer two tendons of the flexor profundus are inserted into the two active inner tendons of the same muscle. The flexor ulnaris is then divided close to its insertion, and between the two portions of its split end the tendons of the flexor sublimis to the four fingers are inserted. The tendon of the extensor carpi radialis longior is now found at the outer border of the incision, and after division is inserted into the tendon of the flexor longus pollicis round the outer border of the radius.

Operation of Transplantation in Complete Paralysis of the Ulnar.

The two inner tendons of the flexor profundus are attached to the two outer.

The palmaris longus is inserted into the tendon of the flexor carpi ulnaris.

After-Treatment.

After operations for musculo-spiral paralysis the hand should be kept dorsiflexed until recovery of the muscle is complete. When the grafted muscles are acting sufficiently

FIG. 10.—Tendon of peroneus longus about to be drawn through the incision opposite the annular ligament under which it has to pass.

FIG. 11.—Tendon of peroneus longus about to be drawn under the annular ligament to be inserted in the tibia.

well and strongly to lift the hand and fingers, the time will have come for gradual training in co-ordination and balanced movement. Even after the patient has learnt to use his hand it is still necessary that he should continue to wear a dorsiflexion splint at night to prevent contractures of the flexors during sleep.

LOWER LIMB.

Paralysis of the Anterior Crural Nerve.

Transplant the sartorius and biceps into the patella.

An alternative measure would be the application of a knee cage with an extension spring to take the place of the paralysed quadriceps. This should be worn permanently.

PARALYSIS OF MUSCLES SUPPLIED BY EXTERNAL POPLITEAL NERVE.

The anterior group of muscles and the peronei are paralysed. The deformity is a dropped foot with varus due to gravity and the uncontrolled action of the muscles attached to the tendo Achillis and of the tibialis posticus.

Tendon Transplantation.

There is not much scope for effective tendon transplantation in this injury, except in cases in which only particular branches of the nerve have been picked out. For instance, an injury paralysing the two peronei muscles, but leaving the anterior tibial nerve intact, would result in a deformity consisting chiefly of inversion of the foot at the mid-tarsal joint—that is, pes varus. In such cases, transplantation of the insertion of the tibialis anticus into the dorsum of the cuboid or into the base of the fifth metatarsal, replaces the loss of the evertors, and restores the balance of the foot.

Tendon Fixation.

In cases of more extensive paralysis there is not sufficient muscle power remaining for it to be effectually distributed; there is, so to say, not enough power to go round. Tendon fixation is then the best operative procedure, for it establishes a firm barrier against drop-foot, and yet allows useful mobility. Tilanus, of Holland, suggested tendon fixation for certain types of flail-foot many years ago, and I am hoping that it will prove increasingly useful in military surgery.

The object of tendon fixation is to utilize the tendons of completely paralysed muscles as accessory ligaments to hold a paralysed foot in a correct position. This can be brought about in an endless variety of ways, and will supply the ingenious surgeon with many interesting and useful problems for reflection. Personally, after many successful operations, I would recommend this method of treatment to meet the disabilities of paralysis due to injury of the external popliteal.

FIG. 13.—Tendon of peroneus longus about to be drawn through the hole drilled in the tibia.

An Operation for Tendon Fixation in Drop-foot due to Injury of the External Popliteal Nerve.

Two small incisions are made along the course of the peroneus longus tendon. The first is placed over the tendon, just before it turns round the outer border of the foot (Fig. 8) on to the sole, and the other about three to

FIG. 12.—Tendon of tibialis anticus being drawn through the foot being kept at right angles; tendon is then cut and passed through a tunnel in the tibia. The tendon of the peroneus longus is shown drawn up through the same opening.

FIG. 14.—Tendon of peroneus longus drawn through the tibia.

FIG. 15.—Tendon of peroneus longus about to be stitched to the periosteum of the tibia.

FIG. 16.—Tendons of peroneus longus and tibialis anticus inserted into a groove made on the surface of the tibia, showing the periosteum raised and drawn aside before being sewn in place.

FIG. 17.—Lower divided portions of the tendons of the peroneus longus and tibialis anticus inserted into the tibia. The upper end of the tendon of the tibialis anticus sutured to the lower end below its insertion in the bone.

four inches above the tip of the external malleolus (Fig. 8).

The tendon is now divided through this upper incision, and the lower freed portion is then pulled out of its sheath through the lower opening while its normal attachment to the sole remains undisturbed (Figs. 8 and 9).

An incision 2 to 3 in. above the tip of the external malleolus is made just external to the anterior border of the tibia, and the divided lower portion of the peroneus longus tendon is passed up from the lower incision to this new one. In its new course the tendon should pass under the anterior annular ligament (Figs. 10 and 11), but if this cannot be done it may be passed in the deep fascial layer (Fig. 19).

The periosteum is now raised from the anterior aspect of the tibia and a deep groove is made in the bone; the tightly pulled tendon, whose outer surface has previously been roughened, is then laid in the groove and is retained in it by a small nail or it is fixed by strong catgut into fascia. The periosteum is then replaced over it (Figs. 16 and 17).

Another effective method of fixing the tendon is to bore a hole through the anterior border of the tibia and pull the tendon through (Figs. 13, 14, and 15). The free end can then be stitched to periosteum, on the inner side of the tibia, or in some cases it may be more convenient to turn the tendon over the crest of the tibia and stitch it to the tendon before it enters the tunnel. Through this same incision the tendon of the tibialis anticus (Fig. 12) is divided and the upper end of the lower portion inserted

FIG. 18.—Diagram to show the anatomy of the area concerned; the three parts of the annular ligament are shown, the tendon of the tibialis anticus is hooked inwards, the tendon of the peroneus longus has been passed under the annular ligament and brought into contact with the tibia.

beneath the periosteum in front of the tibia, in a manner similar to that first described, by nailing, or through a hole bored in the substance of the bone after the second method.

When this has been done the cut end of the upper part

of the tibialis anticus tendon is inserted into the lower part of the tendon distal to its insertion into the tibia (Fig. 17).

The peroneus brevis tendon may then be shortened and inserted into a gutter along the anterior surface of the external malleolus, by another short nail.

If the patient refuses operation he may wear a leather band above the ankle and one round the instep. These leather bands are connected by indiarubber bands sufficiently strong to keep the foot at right angles. The boot can be worn over this.

FIG. 19.—Alternative operation in which the tendon of the peroneus longus is pulled through the subcutaneous tissue without regard to the annular ligament. A. First stage. B. Tendon of peroneus longus drawn upwards and inwards.

Injury to Sciatic Trunk.

If the whole sciatic nerve has been divided high up in the thigh there is total loss of power below the knee and in certain muscles governing the knee-joint. In such cases the patient can walk quite well in a jointed caliper splint with a filling inside the boot to keep the foot at right angles. Another useful plan is to fit a jointed knee cage with a spring and a right-angled support for the ankle. This really means that we make the paralysed distal part of the leg into a species of artificial limb, and this, in actual practice, has proved much better than any artificial limb that I have ever met with.

The idea of rushing to amputation of a limb merely because the sciatic nerve is destroyed and therefore

theoretically the nutrition of the foot must go wrong, is too horrible to be contemplated. Actual experience has proved that, in many cases, the errors of nutrition which ought in theory to occur do not occur, or, at worst, are not nearly so serious as might be expected.

CONCLUSION.

Surgeons will glean from what has been written that there are many ways in which the disabilities following nerve destruction can be met, and that hardly any case is bad enough to justify a counsel of despair. Our knowledge of what can be done in poliomyelitis will invite us to take a cheerful outlook in traumatic paralyses.

This article is intended not merely to indicate ways in which the ground can be prepared for the operations of nerve suturing, or to point out the value of keeping a paralysed muscle relaxed by opposing the force of gravitation, but to indicate the great and ever-increasing field of usefulness that is opened up by utilizing tendon, whether that of an active or a hopelessly paralysed muscle, for the restoration of movement or the correction of deformity, thereby restoring to a greater or less extent the economic efficiency of an individual who will otherwise sink into the position of a non-productive and dependent member of the community.

THE IMPORTANCE OF METHOD IN THE ISOLATION OF PATHOGENIC ORGANISMS OF THE TYPHOID GROUP FROM FAECES.

A FURTHER NOTE ON THE VALUE OF TELLURIC ACID COMBINED WITH BRILLIANT GREEN.

BY

C. H. BROWNING AND L. H. D. THORNTON.

(From the Bland-Sutton Institute of Pathology, Middlesex Hospital.)

THE employment of brilliant green in fluid medium as a means of isolating typhoid and paratyphoid bacilli from faeces, which was originally suggested by Browning, Gilmour and Mackie, and independently by Torrey, for paratyphoid organisms, has now found wide acceptance (Clarke and Stokes, Dreyer, Tidy, as well as other workers whose results are not yet published). The general experience has been that, when used in conjunction with the ordinary direct plating of the faeces on a differential medium like MacConkey's or Endo's, a substantial increase in the number of positive results has been obtained as compared with the latter method alone. As Clarke and Stokes note, however, this statistical result

leaves out of the picture the relative ease of the two methods so far as finding the colonies is concerned. The balance from this point of view is strongly in favour of the brilliant green method, in which it was common to get a practically pure plate of the typhoid group organism.

Accordingly our statement is confirmed that when these specific organisms are found they usually occur in abundance in the subcultures from the brilliant green medium, thus saving much of the time which is taken up in testing a variety of "likely" colonies from the direct plates.

As regards the procedure which has been followed by other workers who have employed brilliant green, it is to be noted that for the most part they have cut down the series of tubes of peptone water containing varying amounts of the dye, which we originally recommended. Thus a single tube containing 0.4 to 0.5 c.cm. of brilliant green 1 in 10,000 in 10 c.cm. of peptone water has been generally employed as representing the optimum concentration. The adjuvant procedure in the form of a further series of tubes containing telluric acid along with brilliant green, in addition to green alone, which was suggested by Browning, Mackie, and Smith, does not appear to have been extensively tested by other investigators. It is, of course, recognized that exigencies of work set a limit to the time which can be devoted to such examinations; but as the paramount importance of leaving no carriers undetected is now generally recognized, it seems desirable that methods should be adopted which will expose the maximum number of cases. The results of others have shown that the use of a single tube of

brilliant green medium will contribute a large proportion of the extra positives detectable by means of this reagent; but in view of the epidemiological significance of carriers it would be an unwise economy of time to rest content with the detection of those carriers which could be found by abbreviated methods and to neglect the further number of cases which could be discovered by suitable means, and which, if overlooked, are probably quite as likely as the rest to constitute foci of infection later on. Thus, provided that there is a definite prospect of adding to the number of positive results, a moderate increase in the amount of attention devoted to the examination of the faeces beyond the inoculation of one direct plate and one tube of brilliant green medium is highly advisable.

The question is, What extension of procedure is likely to yield the best return of further positives? On the basis of our own routine investigations of suspected typhoid-group infections in a large general hospital we would submit that of the means at present available, in addition to direct plating, the employment of a series of tubes of fluid medium containing varying amounts of brilliant green along with a series containing green and telluric acid will probably afford the largest yield of positive results.

As has already been emphasized in these pages (Browning and Thornton), we believe that the employment of a series of doses of the differential reagent in the medium is of the greatest importance. It is obviously a difficult task to arrange such conditions that scanty specific bacteria in a mixture with a large number of biologically similar organisms may undergo selective proliferation so as to enable the former to be isolated in pure culture. The method of making very large surface inoculations on a solid differential medium direct from the faeces, as was done some years ago by Harvey in his important work on the detection of carriers in the army in India,* involves the use of much agar and the search among large numbers of likely colonies, a serious matter where coliform bacilli, which do not produce typical appearances on the differential medium (for example, pale growth on MacConkey's agar), are present. Therefore the use of a simple fluid medium containing differential antiseptics probably yields the best return for the time spent.

In the case of *B. paratyphosus* B the disparity in behaviour between the specific organism and most of the accompanying coliform bacilli is such that brilliant green by itself, in the proportion of 0.5 c.cm. 1 in 10,000 per 10 c.cm. of peptone water, seems to constitute usually a highly suitable medium for isolation. But where one has to deal with smaller differences between the specific organism and the concomitants, as is especially the case with *B. typhosus*, a single concentration of green does not yield the best results (as Clarke and Stokes's figures indicate), and a finer adjustment of the medium becomes necessary. Hence appears the value of using a series of amounts of the differentiating reagent (brilliant green) in the culture of a single specimen of faeces, as the optimum concentration of the dye depends on factors which vary from case to case. Torrey, in employing brilliant green for the isolation of paratyphoid bacilli from faeces, also recognized the importance of the quantitative factor; thus he adopted a fixed concentration of green in glucose bouillon, but added varying amounts of faeces to a series of tubes; subcultures were then made after twenty-four hours' incubation at 37° C. He found that

if the paratyphoid or enteritidis bacilli are fairly numerous in the faeces, pure or nearly pure cultures will develop in all of these tubes. If, however, they are present in very small numbers, the specific growth occurs rather more often in the lightly than in the heavily seeded tubes.

We also employed a relatively light inoculation and found that positive results might be obtained in subcultures from the fluid medium after forty-eight hours' incubation, although the subcultures at twenty-four hours had been negative. Clarke and Stokes, on the other hand, made much heavier inoculations, and found it advisable to subculture earlier (after nine hours).

Here, again, the optimum conditions cannot be determined beforehand, hence the advisability of employing a series of concentrations of the reagent so as to afford a range within which the optimum is likely to lie.

* Harvey used three 9-in. plates of Conradi's medium for each sample of faeces. Each plate required approximately 30 c.cm. of medium, and every likely colony was picked off and investigated.

Further, it has already been pointed out that typhoid bacilli may be isolated from faeces by means of a series of doses of brilliant green and telluric acid, where direct plating, as well as the use of varying amounts of brilliant green alone, both fail to detect their presence (Browning, Mackie, and Smith). The following instance, which recently came under our observation, furnishes a fresh illustration of this latter highly important point. We are indebted to Dr. Pasteur for permission to use the clinical notes of the case.

Woman, aged 34. History of sixteen days' illness; pains in the head and abdomen, with slight abdominal tenderness, vertigo, and profound weakness. The faeces throughout have been firm and well formed. "Rose spots" present; also slight splenic enlargement (maximum recorded temperature 103.4° F.). Previous to the onset of illness the patient had for five weeks nursed a case said to be suffering from typhoid fever. Widal reaction (by the macroscopic method, using Dreyer's emulsion) shows marked agglutination of *B. typhosus* up to 1 in 200 serum dilution after two hours at 55° C. Specimen of faeces (solid, obtained by enema)—one loopful emulsified in 5 c.cm. normal saline; then one large loopful of emulsion added to each tube of medium (1 per cent. peptone water, neutral to litmus; two series (a) containing brilliant green, and (b) brilliant green plus telluric acid).

10 c.cm. Peptone Water containing		Resulting Growth, after Incubation for 24 hours at 37° C., plated on MacConkey's Medium.
Telluric Acid 1 per cent.	Brilliant Green 1:10,000.	
0 ...	0.1 c.cm.	Coliform bacilli.
	0.2 "	" "
	0.35 "	" "
	0.5 "	" "
0.04 c.cm. in each tube	0.7 "	Coliform bacilli which did not ferment inositol.
	0.1 c.cm.	Coliform bacilli.
	0.2 "	" "
	0.35 "	" "
	0.5 "	" "
	0.7 "	<i>B. typhosus</i> in pure culture.

Plate of MacConkey's medium inoculated directly with the faeces showed nothing resembling *B. typhosus* present in more than 100 colonies.

The amount of faeces used was less than that commonly employed by us. As a rule, in the case of very fluid faeces a large loop (up to 1 in. diameter) is employed for inoculation; solid faeces are emulsified by rubbing up with several volumes of sterile water, and then one loopful is used to inoculate each tube.

The results obtained here show (1) that along with a negative result by direct culture on MacConkey's medium—the number of typhoid bacilli present in the faeces constituting probably much less than 1 per cent. of the total viable organisms—(2) no amount of brilliant green up to high doses enabled *B. typhosus* to flourish so as to permit it to be recovered in subcultures, but (3) the mixture of telluric acid and brilliant green yielded in this case a pure growth of *B. typhosus* in the tube containing the highest amount of green, whereas no typhoid bacilli were found in subcultures from any other tubes of the series. We shall not attempt to analyse the multiplicity of factors which may operate in such cases; but the practical issues are clear—namely, that (a) for the successful isolation of *B. typhosus* from faeces varying amounts of the differential reagents may be necessary, and (b) the use of telluric acid along with brilliant green may be essential in order to secure a positive result.

Summary.

1. In the examination of faeces for typhoid and paratyphoid bacilli, the value of a simple fluid medium containing brilliant green, in addition to direct plating, as a means of increasing the number of positive results, has been confirmed by a number of workers.

2. A single fixed concentration of brilliant green (0.5 c.cm. of green 1 to 10,000 per 10 c.cm. of peptone water) seems to leave little to be desired as a medium for the isolation of *B. paratyphosus* B; but this fixed medium does not yield so good results with *B. typhosus*, for which a series of doses of green are required in order to secure the optimum concentration, which depends on a number of variables.

3. In the examination of faeces for *B. typhosus* a series of varying amounts of brilliant green along with telluric acid may be essential in order to isolate this organism in cases where both direct plating and brilliant green alone fail.

MacConkey's agar has been employed, since we have not found that, as prepared here, it compared disadvantageously with Endo's as a medium for the growth of *B. typhosus*.

4. The importance of detecting carriers for the prophylaxis of epidemics should justify the time spent in this extension of the "one-tube" method. Even in its unabbreviated form the procedure compares favourably, as regards consumption both of time and materials, with the old method of spreading a number of large plates directly with the faeces. The fact that the successful subcultures from the fluid medium frequently yield practically pure growths of the pathogenic organism is an important advantage of the method.

EXAMINATION OF FIFTY DYSENTERY CONVALESCENTS FOR CARRIERS.

BY

J. A. ARKWRIGHT, W. YORKE,
TEMPORARY CAPTAINS R.A.M.C.,

O. H. PRIESTLEY, AND W. GILMORE,
TEMPORARY LIEUTENANTS R.A.M.C.

The fifty men examined had all suffered from dysentery contracted on service, and with one exception gave a history of passing blood and slime for periods varying from three days to nine weeks. In four cases a history was also obtained of an illness resembling enteric fever. The convalescents were not selected, but were the first fifty examinations completed in the course of search for carriers in a convalescent camp.

The date of onset of the original illness ranged from May, 1915, to January, 1916, but all except two cases first showed symptoms of dysentery before the end of November, 1915. The examination began on February 16th, and ended on March 24th, 1916.

In every case, therefore, except two the illness began more than two months before the investigation here recorded. The examination of faeces was made in each case on three occasions, an interval of two or three, or occasionally more, days elapsing between the separate observations. The specimens of faeces reached the laboratory within half an hour of being passed. The examination consisted of: (1) Microscopic search for protozoa; (2) plating on MacConkey's neutral red bile-salt lactose agar, and subsequent examination of colourless colonies by means of carbohydrate media and agglutinating serums; (3) a specimen of blood was taken from each man on one occasion and its agglutinating power tested against stock emulsions.

Table showing the Results Obtained by Microscopic Examination and Culture.

<i>Entamoeba histolytica</i> was found in	9 men
<i>E. coli</i> was found in	25 "
<i>Lamblia intestinalis</i> was found in	15 "
<i>B. dysenteriae</i> (Shiga) was found in	2 "
<i>B. dysenteriae</i> (Y) was found in	0 "
<i>B. typhosus</i> , <i>B. paratyphosus</i> A or B was found in	0 "
Negative results (neither protozoa nor bacteria)	14 "

Trichomonas intestinalis was noted in two cases, but was not looked for, especially on account of the need for rapid work. In all the cases in which *Entamoeba histolytica* was recognized *tetragena* cysts were observed, and large or small vegetative forms were also observed in some of these.

Further Analysis of the Results of Microscopic Examination.

<i>Entamoeba</i> was found alone in	6 men
<i>Entamoeba coli</i> was found alone in	12 "
<i>Lamblia intestinalis</i> was found alone in	4 "
<i>E. histolytica</i> and <i>Lamblia</i> were found in	1 man
<i>E. histolytica</i> and <i>E. coli</i> were found in	2 men
<i>E. histolytica</i> and <i>Trichomonas</i> were found in	1 man
Negative	14 men.

THE TREATMENT OF WOUND INFECTIONS.*

BY

W. PARRY MORGAN, M.A., M.B., B.Sc.,

LATE TEMPORARY CAPTAIN R.A.M.C.; FORMERLY ASSISTANT IN THE
DEPARTMENT OF THERAPEUTIC INOCULATION, ST. MARY'S
HOSPITAL, AND IN THE BACTERIOLOGICAL DEPART-
MENT OF THE MEDICAL RESEARCH COMMITTEE.

ATTENTION is being drawn at the present time to the study of the physiological aspect of the treatment of wound infections, and, as a result, new methods, to replace old, have been suggested. In particular, Sir Almroth Wright advocates very strongly giving up treatment by antiseptics for treatment by salt solutions. He does this chiefly on the ground of laboratory experiments, laying it down in respect to treatment that "where the results are neither brilliantly successful nor the reverse . . . we shall be well advised if we guide ourselves, when this is unambiguous, by the verdict of laboratory experiments." Although I have been working with him, I am unable to agree that his experiments conform to this standard, and would for that reason put forward points which appear worthy of further consideration. These relate to: (1) Measures which affect the flow of lymph; (2) measures which affect the flow of pus; (3) antiseptics.

1. Measures which Affect the Flow of Lymph.

In his first lecture on the treatment of wounds Sir Almroth Wright maintained "that we have at disposition an agency for powerfully increasing the outflow of lymph," and asserted that a 5 per cent. solution of common salt "brings into play osmotic forces, and 'draws' the lymph out of the walls of a wound by a *vis a fronte*." In his second lecture, as a result of the criticism that osmotic forces would determine the flow of water and not of lymph, he appeared to give up the notion of osmosis, but otherwise maintained his position. At this lecture he showed four experiments to "bring clearly before the eye the drawing power of salt." For the first, he took a capillary tube open at both ends with an additional opening at its middle. This tube he filled with strong salt solution, and, holding it horizontally, dipped it for a few seconds into a watery solution of methylene blue. On taking the tube out he found that more methylene blue had passed in through the three openings than had happened in the case of a control tube which contained water instead of salt solution. This result we should expect, since salt solution is heavier than water. The salt solution would, for this reason, tend to fall out of the tube, and consequently the methylene blue solution would run in to take its place. The same explanation holds in the case of the second experiment, which was as follows: A piece of glass tubing, plugged with moist cotton-wool, was placed vertically in a vessel containing a watery solution of methylene blue. It was found that the methylene blue travelled up the tube, but travelled higher when salt was placed on the top of the plug. In the third experiment Sir Almroth Wright took a "stab" of watery agar, and on the top placed a cube of salt. In some twelve hours an interchange had taken place, salt passing into the agar and water to the salt. This he gave as a demonstration of what he expected—namely, "a process of barter in which salt and water should be exchanged, not in volumetric equivalents, but in the ratio of very many volumes of fluid for one of the solid." As a matter of fact, the volume of fluid in such a case is not greater than the volume of solid, and the experiment is merely a demonstration of the diffusibility of salt in agar. The fourth experiment was similar, but in this case the stab consisted of blood agar. Here the presence of the albuminous substances in the fluid which collected above the agar showed only that such substances diffuse in agar in the same way as salt, and not that salt draws lymph. It is therefore clear that these experiments do not support the view that hypertonic solution will draw lymph out of a wound.

Again, Sir Almroth Wright, in his discourse, asserted that it was "confusion of thought" which led to the belief "that it is the interposition of the sieve which confers upon salt the power of drawing water to itself." Such an assertion is really a denial of Newton's third law, which lays it down that action and reaction are equal and opposite. For it follows from this law that salt would be

drawn to water by forces equal to any which would draw water to salt. Consequently, unless a sieve supported and held back salt, while not at the same time preventing the passage of water, there could not be such a process of barter as Sir Almroth Wright suggests. It is plain, then, that the only sense in which salt can be said to draw "water" to itself is that recognized when such a process as osmosis takes place. But salt cannot be said to draw lymph to itself even by osmosis, because albuminous substances cannot pass through membranes impermeable to salt. On the contrary, it might be said that since animal membranes are usually permeable to crystalloids and not to colloids an albuminous substance may by osmosis "draw" salt to itself.

Having seen that salt does not draw lymph by a *vis a fronte*, we may examine how the outflow can be influenced. We shall only deal with those ways which are clearly physical. For these to be operative, we must presume that the lymph spaces and channels, potential and otherwise, are open to the surface, and that a fluid pressure greater than atmospheric tends to drive lymph out through them. The flow will then be at a rate depending on the pressure in the tissues and on the number and size of the channels. As regards the pressure, it is plain that this will vary with the hyperaemia, and so we may expect that any measure which favours hyperaemia will also act as a lymphagogue. Again, as regards the channels, we see that they may be obstructed (1) by dried lymph on the surface blocking the outlets; (2) by the cellular walls coming together and obliterating such channels. The application of any moist dressing will usually remedy the first, and is as a rule sufficient. In this connexion it must not be thought that moist coagulated lymph will necessarily prevent drainage. After all, it is merely a meshwork of fibrin in which the leucocytes can move and function. It is hardly comparable with a membrane, and is pervious unless it becomes blocked by pus cells. The obstruction due to this and to the obliteration of the channels can be relieved if we can abstract fluid from the cells. This can be done by the application of hypertonic solutions, which would cause an osmotic diffusion of water out of the cells. The cells would then shrink and the obliterated channels open up, just as the ground is fissured in dry weather. The result would be that the lymph would have free passage to the surface and the lymph-bound condition be relieved. This action of hypertonic solutions can readily be demonstrated by trying to filter fluids through agar containing blood corpuscles. Owing to the osmotic crenation and shrinkage of the corpuscles which they cause, hypertonic solutions go through comparatively readily, while the isotonic are held back.

But it is hardly to be expected that the direct osmotic effect of salt in a wound will be more than a very superficial one, for, once a flow is established, the current of lymph outwards will tend to counteract the diffusion of salt inwards. Thus, as soon as the surface becomes pervious, the presence of hypertonic solutions cannot be expected still further to increase the flow. Again, it does not necessarily happen that the osmotic effect of hypertonic solutions will always produce conditions favourable to a flow. From a clinical point of view, this is made clear by Colonel H. M. W. Gray,¹ who, at Rouen, in a lecture strongly advocating the use of hypertonic salt solution as a lymphagogue, gave away much of his case by pointing out that salt tabloid packs, so far from producing a flow, frequently became dry after twenty-four hours.

It may be observed here that the effect of hypotonic fluids, such as tap water, hydrogen peroxide, and iodine solutions, have the opposite effect to hypertonic fluids, and would cause the surface cells to swell. This swelling may be expected to bring about a diminished flow of lymph. It is therefore desirable that the excipient used for antiseptics should be isotonic with the blood fluids. For this reason we ought to dilute antiseptics with physiological saline, unless they are incompatible, and not, as is usually done, with water.

2. Measures which Affect the Flow of Pus.

Here, again, Sir Almroth Wright claims that he has a specific, this time in physiological saline, asserting that "the white corpuscles are carried forward by a chemio-tactic movement in the direction of the free surface upon

* Read at the Royal Society of Medicine, Pathological Section, on May 2nd, 1916 (see p. 689).

which the physiological solution has been imposed." I would venture, however, to examine in fuller detail the experiments on which he bases this claim, and whether it is warranted by them.

Taking flat capillary tubes containing unclotted blood, he centrifugalized this before it had time to clot. When clotting had taken place there was then in the tube a clot consisting of a red corpuscular portion (a), a white plasma portion (c), and between these, joining them, a narrow portion containing white corpuscles (b). He then superimposed upon these clots a "chemiotactic agent," such as saline, and incubated them. The clots were afterwards removed from the tubes, mounted on slides, and stained. It was observed in many cases that, if the temperature was in the neighbourhood of body temperature, the leucocytes had wandered or emigrated into the white clot. It was on experiments of this nature that Sir Almroth Wright based his statements regarding chemiotaxis.

We may get help in understanding the behaviour of the leucocytes in these experiments if we consider the ways in which the clot tends to contract, and, for this purpose, it is what happens in the neighbourhood of the leucocytic layer of the clot which is of importance as once the leucocytes have moved well out into the white clot they appear to remain there. Sometimes, as Sir Watson Cheyne points out,² there is no contraction (Fig. 1, A). At other times contraction takes place at the junction of the red and white clots (Fig. 1, B, C), and a neck containing most of the leucocytes is formed. This neck may lie wholly free in serum (Fig. 1, B), or partially in contact with the walls of the tube (Fig. 1, C). When it lies wholly free in serum, it becomes highly probable that the wandering movements of the leucocytes will result in their finding a way laterally out of the clot into the serum more readily than along the axis, and thus we would expect to find, in such a case, no emigration. On the other hand, when the neck of the clot lies partly in contact with the tube, the leucocytes in that situation would not be able to pass out of the clot, and so they would be more likely to travel along the axis and show emigration. These expectations accord with what is actually seen to take place. In my own experiments I found

FIG. 1.—Emigration tubes showing different types of contraction. (a) red clot, (b) leucocytic layer, (c) white clot, (d) superimposed fluid. A. No contraction; free emigration shown. B. Contraction with the formation of a neck at the leucocytic portion of the clot, which lies free in serum; emigration is not shown in this. C. Contraction similar to B, but the neck is partly in contact with the tube; emigration shown. D. Chemiotactic agent superimposed; retraction of clot along its axis; leucocytic layer in contact with the tube; emigration shown; this clot is not so likely to contract in mounting, so that the distance which leucocytes traverse would appear greater than in those from A and C.

In some cases practically no polynuclear cells in the white clot, and only a few mononuclear near the neck. This occurred both with and without the addition of the chemiotactic agent. In other cases the leucocytes travelled along the clot, especially the more active polynuclear. This also occurred both with and without the addition of the chemiotactic agent. Some of the specimens, showing ultimately no emigration, where no chemiotactic agent had been applied, I examined from time to time on a warm stage, where the movements of the leucocytes could be watched. At first near the neck, they could be seen moving actively in all directions, but later they disappeared out of the clot. When mounting these specimens, I collected the serum which had exuded from the clot, and found a very large number of leucocytes in the exudate. Subsequent examination of the tubes, which, after the clot had been removed, were immediately filled with fresh serum, also revealed large numbers of leucocytes adhering

to the walls and showing active movements. Hence the polynuclear leucocytes do, without the application of a chemiotactic agent, wander into the clot and then out into the serum. It is clear, therefore, that Sir Almroth Wright can hardly be justified in supposing that emigration due to wandering or "eleutherotropic" movement is predominantly mononuclear and that polynuclear emigration is chemiotactic. This variable loss of leucocytes from the clot to the serum, clearly independent of any possible chemiotactic influence, shows that it is as futile to aim at measuring quantitatively the emigration movements and chemiotactic effects by estimating the number of leucocytes which remain in the white clot at different distances from the red as it would be to estimate the total number of a company after an unknown proportion had retired. But even when free emigration takes place in the presence of physiological saline it cannot be said to be due to chemiotaxis, for the distance traversed by the leucocytes is little or no greater than when no fluid but serum is present, whereas if such emigration were due to chemiotaxis—that is, "a directed movement along a particular axis undertaken under the direction of a chemical stimulus"—one would expect great differences. The small differences that are occasionally seen may be explained by a slight effect which physiological saline may possibly have in increasing the non-directed wandering movements of the leucocytes. This effect is apparently shown in some specimens obtained by mixing saline with blood before it clots, circumstances in which there could be no chemiotaxis. But even admitting this stimulation, it is doubtful whether it is of any value. For the leucocytes would not start their wanderings in larger numbers, but only travel faster through the infected tissues, and act there for a shorter time. Again, physiological saline would not increase the all-important function of phagocytosis. I submit, therefore, that laboratory results, as yet, give no grounds for asserting that we have in physiological saline an agent which will advantageously affect the activities of the leucocytes and the flow of pus into a wound.
